1 Overview

1.1 What Is MRS?

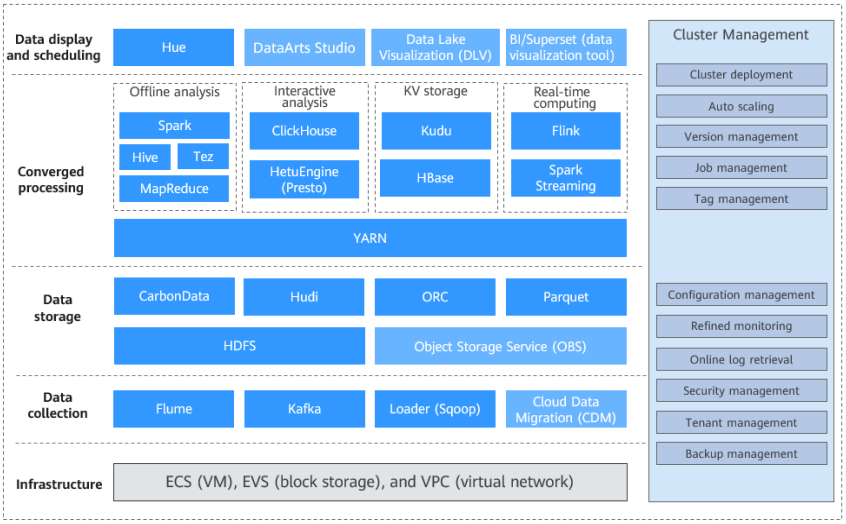
Big data is a huge challenge facing the Internet era as the data volume and types increase rapidly. Conventional data processing technologies, such as single-node storage and relational databases, are unable to solve the emerging big data problems. In this case, the Apache Software Foundation (ASF) has launched an open source Hadoop big data processing solution. Hadoop is an open source distributed computing platform that can fully utilize computing and storage capabilities of clusters to process massive amounts of data. If enterprises deploy Hadoop systems by themselves, the disadvantages include high costs, long deployment period, difficult maintenance, and inflexible use.

To address these issues, MapReduce Service (MRS) is provided on the cloud for you to manage Hadoop-based components. With MRS, you can deploy a Hadoop cluster with a few clicks. MRS provides enterprise-level big data clusters on the cloud. Tenants can fully control clusters and easily run big data components such as Hadoop, Spark, HBase, and Kafka. MRS is fully compatible with open source APIs, and incorporates advantages of the cloud computing and storage and big data industry experience to provide customers with a full-stack big data platform featuring high performance, low cost, flexibility, and ease-of-use. In addition, the platform can be customized based on service requirements to help enterprises quickly build a massive data processing system and discover new value points and business opportunities by analyzing and mining massive amounts of data in real time or in non-real time.

Product Architecture

Figure 1-1 shows the MRS logical architecture.

Figure 1-1 MRS architecture



MRS architecture includes infrastructure and big data processing phases.

- Infrastructure

  MRS big data clusters are built based on Elastic Cloud Server (ECS), and fully utilizes the high reliability and security capabilities of the virtualization layer.

  - A Virtual Private Cloud (VPC) is a virtual internal network provided for each tenant. It is isolated from other networks by default.
  - Elastic Volume Service (EVS) provides highly reliable and high-performance storage.
  - ECS provides scalable VMs, and works with VPCs, security groups, and the EVS multi-replica mechanism to build an efficient, reliable, and secure computing environment.

- Data collection

  The data collection layer provides the capability of importing data from various dta sources, such as Flume (data ingestion), Loader (relational data import), and Kafka (highly reliable message queue), to MRS big data clusters. Alternatively, you can use Cloud Data Migration (CDM) to import external data to MRS clusters.

- Data storage

  MRS clusters can store structured and unstructured data, and support multiple efficient formats to meet the requirements of different computing engines.

  - HDFS is a general-purpose distributed file system on a big data platform.
  - OBS is an object storage service that features high availability and low cost.
  - HBase supports data storage with indexes, and is applicable to high-performance index-based query scenarios.

- Data convergence processing

  - MRS provides multiple mainstream compute engines, including MapReduce (batch processing), Tez (DAG model), Spark (in-memory computing), Spark Streaming (micro-batch stream computing), and Flink

(stream computing), to convert data structures and logic into data models that meet service requirements in a variety of big data application scenarios.
  - Based on the preset data model and easy-to-use SQL data analysis, users can select Hive (data warehouse), SparkSQL, and Presto (interactive query engine).
- Data display and scheduling

  Displays data analysis results and integrates with DataArts Studio to provide a one-stop big data collaborative development platform, helping you easily complete multiple tasks, such as data modeling, data integration, script development, job scheduling, and O&M monitoring, making big data more accessible than ever before, and helping you effortlessly build big data processing centers.
- Cluster management

  All components of the Hadoop-based big data ecosystem are deployed in distributed mode, and their deployment, management, and O&M are complex.

  MRS provides a unified O&M management platform for cluster management, supporting one-click cluster deployment, multi-version selection, as well as manual scaling and auto scaling of clusters without service interruption. In addition, MRS provides job management, resource tag management, and O&M of the preceding data processing components at each layer. It also provides one-stop O&M capabilities, covering monitoring, alarm reporting, configuration, and patch upgrade.

Product Advantages

MRS has a powerful Hadoop kernel team and is deployed based on enterprise-level FusionInsight big data platform. MRS has been deployed on tens of thousands of nodes and can ensure Service Level Agreements (SLAs) for multi-level users.

MRS has the following advantages:

- High performance

  MRS supports self-developed CarbonData storage technology. CarbonData is a high-performance big data storage solution. It allows one data set to apply to multiple scenarios and supports features, such as multi-level indexing, dictionary encoding, pre-aggregation, dynamic partitioning, and quasi-real-time data query. This improves I/O scanning and computing performance and returns analysis results of tens of billions of data records in seconds. In addition, MRS supports self-developed enhanced scheduler Superior, which breaks the scale bottleneck of a single cluster and is capable of scheduling over 10,000 nodes in a cluster.
- Cost-effectiveness

  Based on diversified cloud infrastructure, MRS provides various computing and storage choices and separates computing from storage, delivering cost-effective massive data storage solutions. MRS supports auto scaling to address peak and off-peak service loads, releasing idle resources on the big data platform for customers. MRS clusters can be created and scaled out when you need them, and can be terminated or scaled in after you use them, minimizing cost.

- High security

  MRS delivers enterprise-level big data multi-tenant permissions management and security management to support table-based and column-based access control and data encryption.

- Easy O&M

  MRS provides a visualized big data cluster management platform, improving O&M efficiency. MRS supports rolling patch upgrade and provides visualized patch release information and one-click patch installation without manual intervention, ensuring long-term stability of user clusters.

- High reliability

  The proven large-scale reliability and long-term stability of MRS meet enterprise-level high reliability requirements. In addition, MRS supports automatic data backup across AZs and regions, as well as automatic anti-affinity. It allows VMs to be distributed on different physical machines.

1.2 Application Scenarios

Big data is ubiquitous in our lives. MRS is suitable to process big data in the industries such as the Internet of things (IoT), e-commerce, finance, manufacturing, healthcare, energy, and government departments.

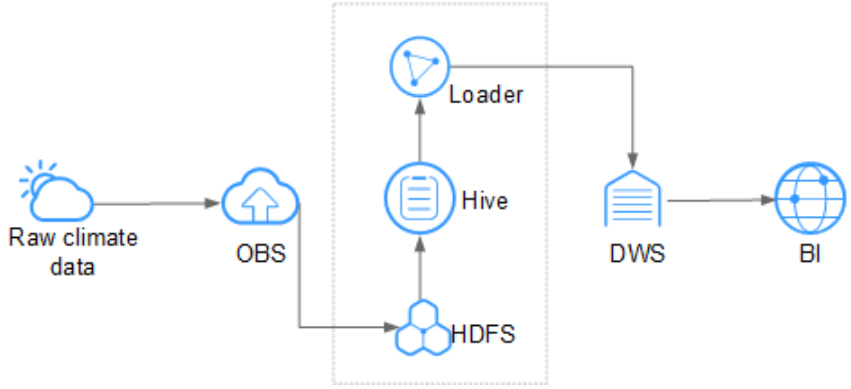
Large-scale data analysis

Large-scale data analysis is a major scenario in modern big data systems. Generally, an enterprise has multiple data sources. After data is accessed,extract, transform, and load (ETL) processing is required to generate modelized data for each service module to analyze and sort out data. This type of service has the following characteristics:

- The requirements for real-time execution are not high, and job execution time ranges from dozens of minutes to hours.
- The data volume is large.
- There are various data sources and diversified formats.
- Data processing usually consists of multiple tasks, and resources need to be planned in detail.

In the environmental protection industry, climate data is stored on OBS and periodically dumped into HDFS for batch analysis. 10 TB of climate data can be analyzed in 1 hour.

Figure 1-2 Large-scale data analysis in the environmental protection industry



MRS has the following advantages in this scenario.

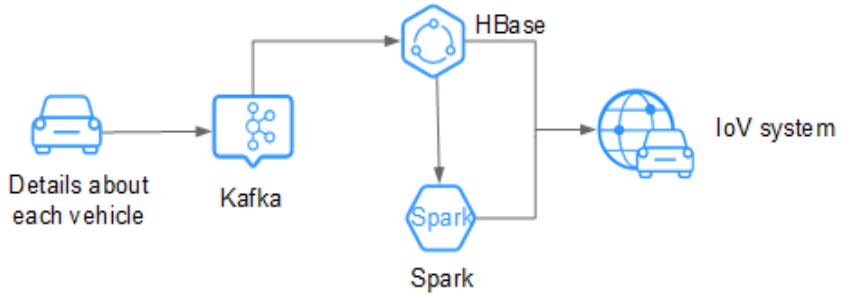
- Low cost: OBS offers cost-effective storage.
- Massive data analysis: TB/PB-level data is analyzed by Hive.
- Visualized data import and export tool: Loader exports data to Data Warehouse Service (DWS) for business intelligence (BI) analysis.

Large-scale data storage

A user who has a large amount of structured data usually requires index-based quasi-real-time query capabilities. For example, in an Internet of Vehicles (IoV) scenario, vehicle maintenance information is queried by vehicle number. Therefore, vehicle information is indexed based on vehicle numbers when it is being stored, to implement second-level response in this scenario. Generally, the data volume is large. The user may store data for one to three years.

For example, in the IoV industry, an automobile company stores data on HBase, which supports PB-level storage and CDR queries in milliseconds.

Figure 1-3 Large-scale data storage in the IoV industry



MRS has the following advantages in this scenario.

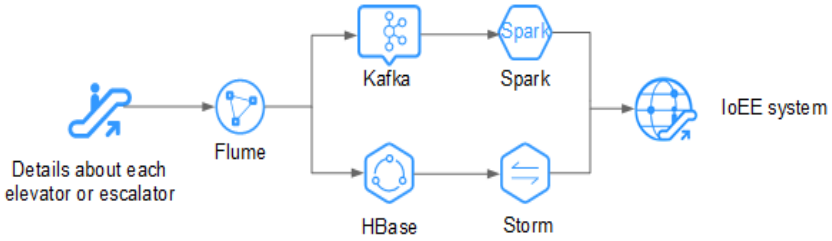
- Real time: Kafka accesses massive amounts of vehicle messages in real time.
- Massive data storage: HBase stores massive volumes of data and supports data queries in milliseconds.
- Distributed data query: Spark analyzes and queries massive volumes of data.

Real-time data processing

Real-time data processing is usually used in scenarios such as anomaly detection, fraud detection, rule-based alarming, and service process monitoring. Data is processed while it is being inputted to the system.

For example, in the Internet of elevators & escalators (IoEE) industry, data of smart elevators and escalators is imported to MRS streaming clusters in real time for real-time alarming.

Figure 1-4 Low-latency streaming processing in the IoEE industry



MRS has the following advantages in this scenario.

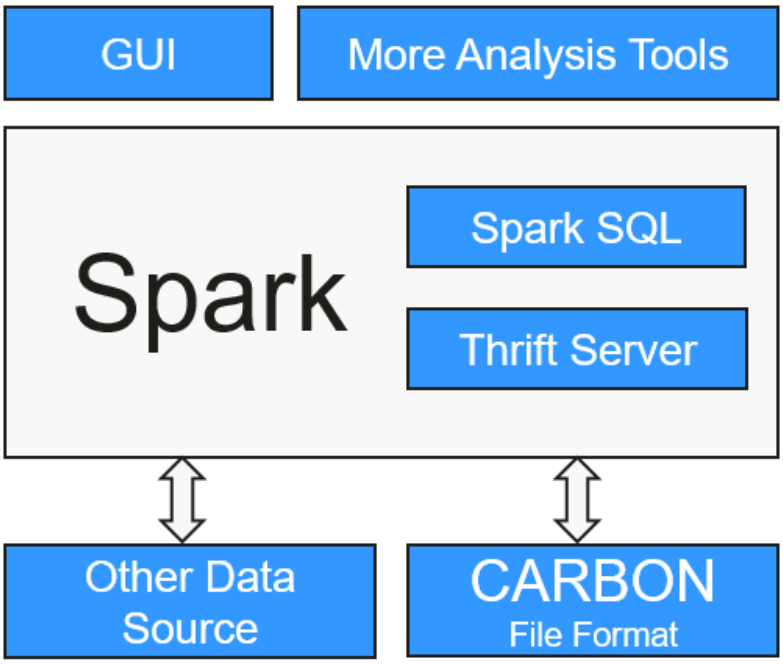
- Real-time data ingestion: Flume implements real-time data ingestion and provides various data collection and storage access methods.
- Data source access: Kafka accesses data of tens of thousands of elevators and escalators in real time.

1.3 Components

1.3.1 CarbonData

CarbonData is a new Apache Hadoop native data-store format. CarbonData allows faster interactive queries over PetaBytes of data using advanced columnar storage, index, compression, and encoding techniques to improve computing efficiency. In addition, CarbonData is also a high-performance analysis engine that integrates data sources with Spark.

Figure 1-5 Basic architecture of CarbonData



The purpose of using CarbonData is to provide quick response to ad hoc queries of big data. Essentially, CarbonData is an Online Analytical Processing (OLAP) engine, which stores data using tables similar to those in Relational Database Management System (RDBMS). You can import more than 10 TB data to tables created in CarbonData format, and CarbonData automatically organizes and stores data using the compressed multi-dimensional indexes. After data is loaded to CarbonData, CarbonData responds to ad hoc queries in seconds.

CarbonData integrates data sources into the Spark ecosystem. You can use Spark SQL to query and analyze data, or use the third-party tool ThriftServer provided by Spark to connect to Spark SQL.

CarbonData features

- SQL: CarbonData is compatible with Spark SQL and supports SQL query operations performed on Spark SQL.
- Simple Table dataset definition: CarbonData allows you to define and create datasets by using user-friendly Data Definition Language (DDL) statements. CarbonData DDL is flexible and easy to use, and can define complex tables.
- Easy data management: CarbonData provides various data management functions for data loading and maintenance. It can load historical data and incrementally load new data. The loaded data can be deleted according to the loading time and specific data loading operations can be canceled.
- CarbonData file format is a columnar store in HDFS. It has many features that a modern columnar format has, such as splittable and compression schema.

Unique features of CarbonData

- Stores data along with index: Significantly accelerates query performance and reduces the I/O scans and CPU resources, when there are filters in the query. CarbonData index consists of multiple levels of indices. A processing

framework can leverage this index to reduce the task it needs to schedule and process, and it can also perform skip scan in more finer grain unit (called blocklet) in task side scanning instead of scanning the whole file.

- Operable encoded data: Through supporting efficient compression and global encoding schemes, CarbonData can query on compressed/encoded data. The data can be converted just before returning the results to the users, which is "late materialized".
- Supports various use cases with one single data format: like interactive OLAP-style query, Sequential Access (big scan), and Random Access (narrow scan).

Key technologies and advantages of CarbonData

- Quick query response: CarbonData features high-performance query. The query speed of CarbonData is 10 times of that of Spark SQL. It uses dedicated data formats and applies multiple index technologies, global dictionary code, and multiple push-down optimizations, providing quick response to TB-level data queries.
- Efficient data compression: CarbonData compresses data by combining the lightweight and heavyweight compression algorithms. This significantly saves 60% to 80% data storage space and the hardware storage cost.

1.3.2 ClickHouse

Introduction to ClickHouse

ClickHouse is an open-source columnar database oriented to online analysis and processing. It is independent of the Hadoop big data system and features ultimate compression rate and fast query performance. In addition, ClickHouse supports SQL query and provides good query performance, especially the aggregation analysis and query performance based on large and wide tables. The query speed is one order of magnitude faster than that of other analytical databases.

The core functions of ClickHouse are as follows:

Comprehensive DBMS functions

ClickHouse has a complete Database Management System (DBMS), and has the following basic functions:

- Data Definition Language (DDL): allows databases, tables, and views to be dynamically created, modified, or deleted without restarting services.
- Data Manipulation Language (DML): allows data to be queried, inserted, modified, or deleted dynamically.
- Permission control: supports user-based database or table operation permission settings to ensure data security.
- Data backup and restoration: supports data backup, export, import, and restoration to meet the requirements of the production environment.
- Distributed management: provides the cluster mode to automatically manage multiple database nodes.

Column-based storage and data compression

ClickHouse is a database that uses column-based storage. Data is organized by column. Data in the same column is stored together, and data in different columns is stored in different files.

During data query, columnar storage can reduce the data scanning range and data transmission size, thereby improving data query efficiency.

In a traditional row-based database system, data is stored in the sequence in **Table 1-1**:

Table 1-1 Row-based database

row	ID	Flag	Name	Event	Time
0	12345678901	0	name1	1	2020/1/11 15:19
1	32345678901	1	name2	1	2020/5/12 18:10
2	42345678901	1	name3	1	2020/6/13 17:38
N	...	...	...	...	...

In a row-based database, data in the same row is physically stored together. In a column-based database system, data is stored in the sequence in **Table 1-2**:

Table 1-2 Columnar database

row:	0	1	2	N
ID:	12345678901	32345678901	42345678901	...
Flag:	0	1	1	...
Name:	name1	name2	name3	...
Event:	1	1	1	...
Time:	2020/1/11 15:19	2020/5/12 18:10	2020/6/13 17:38	...

This example shows only the arrangement of data in a columnar database. Columnar databases store data in the same column together and data in different columns separately. Columnar databases are more suitable for online analytical processing (OLAP) scenarios.

Vectorized executor

ClickHouse uses CPU's Single Instruction Multiple Data (SIMD) to implement vectorized execution. SIMD is an implementation mode that uses a single instruction to operate multiple pieces of data and improves performance with data

parallelism (other methods include instruction-level parallelism and thread-level parallelism). The principle of SIMD is to implement parallel data operations at the CPU register level.

Relational model and SQL query

ClickHouse uses SQL as the query language and provides standard SQL query APIs for existing third-party analysis visualization systems to easily integrate with ClickHouse.

In addition, ClickHouse uses a relational model. Therefore, the cost of migrating the system built on a traditional relational database or data warehouse to ClickHouse is lower.

Data sharding and distributed query

The ClickHouse cluster consists of one or more shards, and each shard corresponds to one ClickHouse service node. The maximum number of shards depends on the number of nodes (one shard corresponds to only one service node).

ClickHouse introduces the concepts of local table and distributed table. A local table is equivalent to a data shard. A distributed table itself does not store any data. It is an access proxy of the local table and functions as the sharding middleware. With the help of distributed tables, multiple data shards can be accessed by using the proxy, thereby implementing distributed query.

ClickHouse Applications

ClickHouse is short for Click Stream and Data Warehouse. It is initially applied to a web traffic analysis tool to perform OLAP analysis for data warehouses based on page click event flows. Currently, ClickHouse is widely used in Internet advertising, app and web traffic analysis, telecommunications, finance, and Internet of Things (IoT) fields. It is applicable to business intelligence application scenarios and has a large number of applications and practices worldwide.

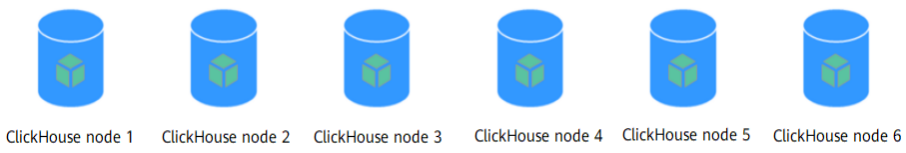
ClickHouse Enhanced Open Source Features

MRS ClickHouse has advantages such as automatic cluster mode, HA deployment, and smooth and elastic scaling.

- Automatic Cluster Mode

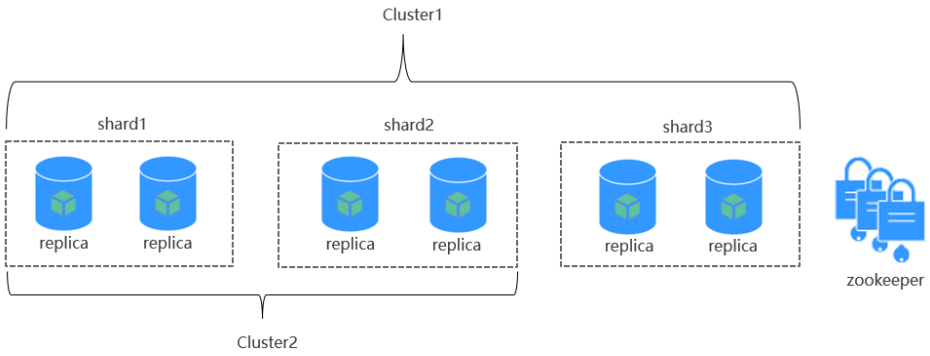
  As shown in **Figure 1-6**, a cluster consists of multiple ClickHouse nodes, which has no central node. It is more of a static resource pool. If the ClickHouse cluster mode is used for services, you need to pre-define the cluster information in the configuration file of each node. Only in this way, services can be correctly accessed.

  Figure 1-6 ClickHouse cluster

Users are unaware of data partitions and replica storage in common database systems. However, ClickHouse allows you to proactively plan and define detailed configurations such as shards, partitions, and replica locations. The ClickHouse instance of MRS packs the work in a unified manner and adapts it to the automatic mode, implementing unified management, which is flexible and easy to use. A ClickHouse instance consists of three ZooKeeper nodes and multiple ClickHouse nodes. The Dedicated Replica mode is used to ensure high reliability of dual data copies.

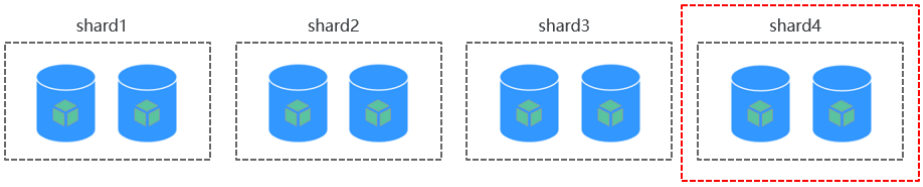
Figure 1-7 ClickHouse cluster structure



- Smooth and Elastic Scaling

  As business grows rapidly, MRS provides ClickHouse, a data migration tool, for scenarios such as the cluster's storage capacity or CPU compute resources approaching the limit. This tool is used to migrate some partitions of one or multiple MergeTree tables on several ClickHouseServer nodes to the same tables on other ClickHouseServer nodes. In this way, service availability is ensured and smooth capacity expansion is implemented.

  When you add ClickHouse nodes to a cluster, use this tool to migrate some data from the existing nodes to the new ones for data balancing after the expansion.



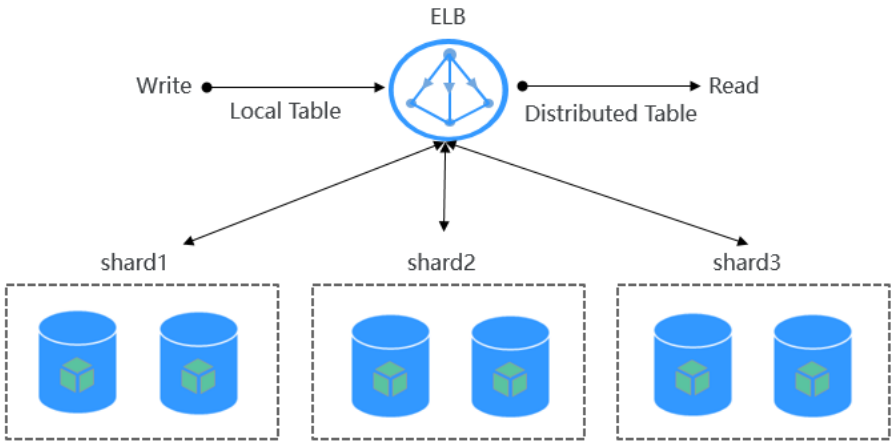
- HA Deployment Architecture

  MRS uses the ELB-based high availability (HA) deployment architecture to automatically distribute user access traffic to multiple backend nodes, expanding service capabilities to external systems and improving fault tolerance. As shown in **Figure 1-8**, when a client application requests a cluster, Elastic Load Balance (ELB) is used to distribute traffic. With the ELB polling mechanism, data is written to local tables and read from distributed tables on different nodes. In this way, data read/write load and high availability of application access are guaranteed.

  After the ClickHouse cluster is provisioned, each ClickHouse instance node in the cluster corresponds to a replica, and two replicas form a logical shard. For example, when creating a ReplicatedMergeTree table, you can specify shards

so that data can be automatically synchronized between two replicas in the same shard.

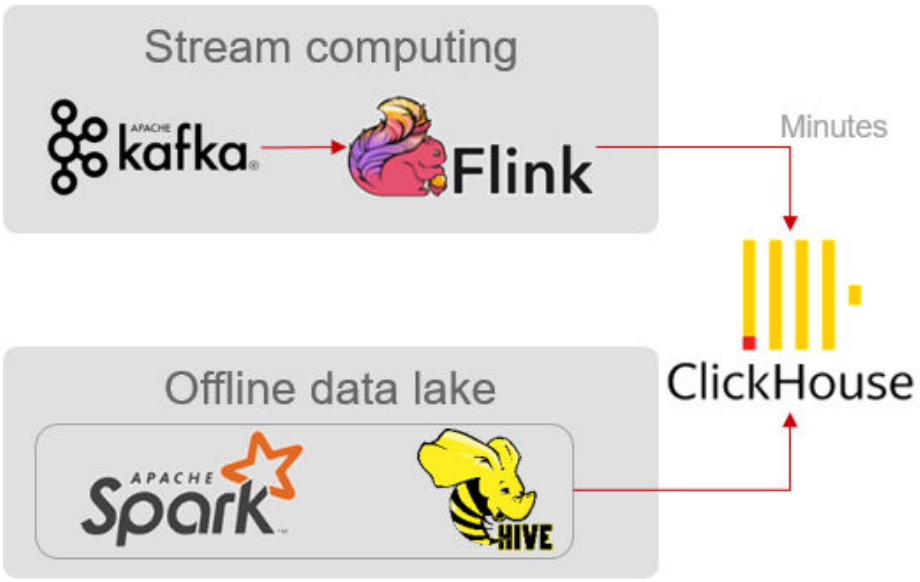
Figure 1-8 HA deployment architecture



Relationship Between ClickHouse and Other Components

ClickHouse depends on ZooKeeper for installation and deployment.

Flink stream computing applications are used to generate common report data (detail flat-wide tables) and write the report data to ClickHouse in quasi-real time. Hive/Spark jobs are used to generate common report data (detail flat-wide tables) and batch import the data to ClickHouse.



NOTE

Currently, ClickHouse does not support interconnection with Kafka in normal mode or HDFS in security mode.

1.3.3 DBService

1.3.3.1 DBService Basic Principles

Overview

DBService is a HA storage system for relational databases, which is applicable to the scenario where a small amount of data (about 10 GB) needs to be stored, for example, component metadata. DBService can only be used by internal components of a cluster and provides data storage, query, and deletion functions.

DBService is a basic component of a cluster. Components such as Hive, Hue, Oozie, Loader, and Redis, and Loader store their metadata in DBService, and provide the metadata backup and restoration functions by using DBService.

DBService Architecture

DBService in the cluster works in active/standby mode. Two DBServer instances are deployed and each instance contains three modules: HA, Database, and FloatIP.

Figure 1-9 shows the DBService logical architecture.

Figure 1-9 DBService architecture

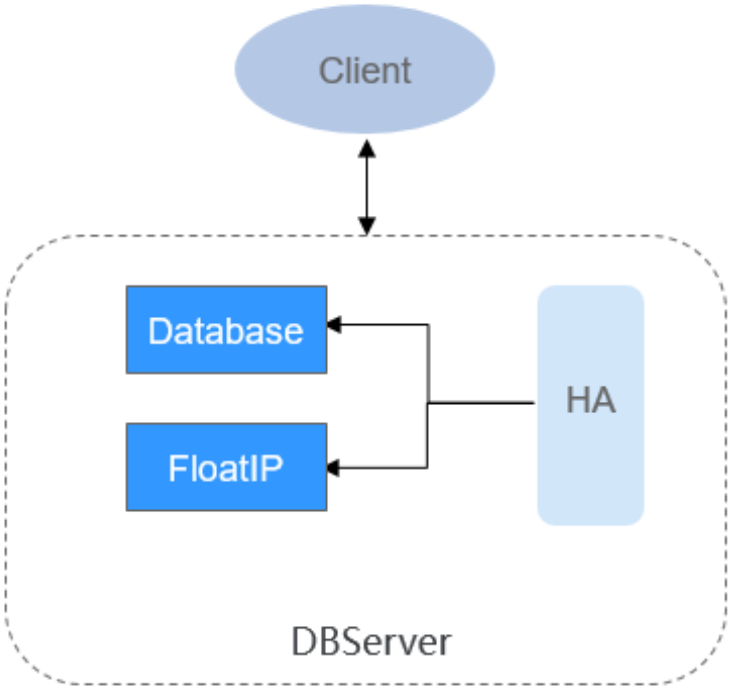


Table 1-3 describes the modules shown in **Figure 1-9**

Table 1-3 Module description

Name	Description
HA	HA management module. The active/standby DBServer uses the HA module for management.
Database	Database module. This module stores the metadata of the Client module.
FloatIP	Floating IP address that provides the access function externally. It is enabled only on the active DBServer instance and is used by the Client module to access Database.
Client	Client using the DBService component, which is deployed on the component instance node. The client connects to the database by using FloatIP and then performs metadata adding, deleting, and modifying operations.

1.3.3.2 Relationship Between DBService and Other Components

DBService is a basic component of a cluster. Components such as Hive, Hue, Oozie, Loader, Metadata, and Redis, and Loader store their metadata in DBService, and provide the metadata backup and restoration functions by using DBService.

1.3.4 Doris

1.3.4.1 Basic Principles

Introduction to Doris

Doris is a high-performance, real-time analytical database based on MPP architecture, known for its extreme speed and ease of use. It can return query results of mass data in sub-seconds and can support high-concurrency point queries and high-throughput complex analysis. All this makes Apache Doris an ideal tool for report analysis, ad-hoc query, unified data warehouse, and data lake query acceleration. On Doris, users can build various applications, such as user behavior analysis, AB test platform, log retrieval analysis, user portrait analysis, and order analysis.

Doris Architecture

The following figure shows the overall architecture of Doris. The frontend and backend nodes can be expanded horizontally and infinitely.

Figure 1-10 Doris architecture

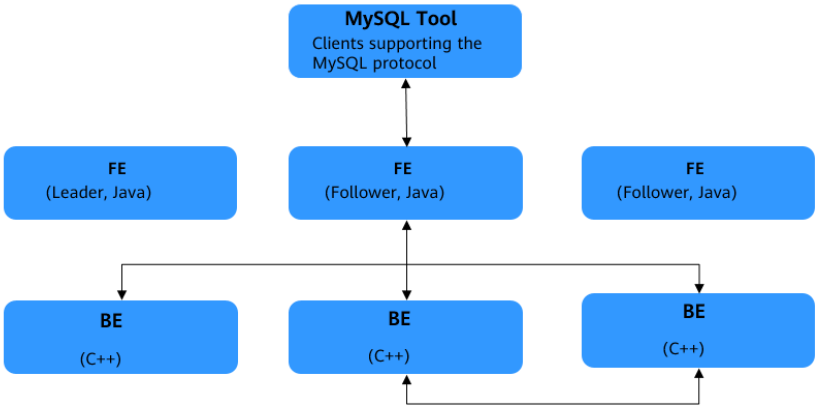

Table 1-4 Description

Parameter	Description
MySQL Tools	Doris is highly compatible with MySQL syntax and is accessible by various client tools. It also supports standard SQL statements and interconnection with BI tools.
FE	Frontend nodes process user access requests, plan query parsing, and manage metadata and nodes.
BE	Stores data, executes query plans, and balances load among copies.
Leader	Leader is a role elected from the Follower group.
Follower	A metadata log needs to be written successfully in most Follower nodes.

Doris uses the MPP model. Inter-node and intra-node parallel execution is used, which is applicable to distributed join of multiple large tables.

Supports vectorized query engines, AQE (Adaptive Query Execution) technology, CBO-RBO optimization policies, and hot data cache query.

Basic Concepts of Doris

In Doris, data is logically described in the form of tables.

- **Row&Column**

  A table consists of rows and columns.

  – Row: a row of user data.

  - Column: describes different fields in a row of data.

  Columns can be classified into two types: key and value. From the service perspective, Key and Value can correspond to dimension columns and metric columns, respectively. From the perspective of the aggregation model, rows with the same Key column are aggregated into one row. The aggregation mode of the Value column is specified when the table is created.

- **Tablet&Partition**

  In the Doris storage engine, user data is horizontally divided into several data shards (tablets, also called data buckets). Each tablet contains several rows of data. The data between the individual tablets does not intersect and is physically stored independently.

  Multiple tables logically belong to different partitions. A table belongs to only one partition, but a partition contains multiple tables. Since the tablets are physically stored independently, the partitions can be seen as physically independent, too. Tablet is the smallest physical storage unit for data operations such as movement and replication.

  Multiple partitions form a table. A partition can be regarded as the smallest logical management unit. Data can be imported or deleted only for one partition.

- **Data Models**

  Doris data models are classified into three types: Aggregate, Unique, and Duplicate.

  - Aggregate models

    When data is imported, rows with the same Key column are aggregated into one row, and the Value column is aggregated based on the configured AggregationType. Currently, AggregationType has the following four aggregation modes:

    - SUM: Accumulate the values in multiple rows.
    - REPLACE: The newly imported value replaces the previous value.
    - MAX: Keep the maximum value.
    - MIN: Keep the minimum value.

  - Unique model

    In some multi-dimensional analysis scenarios, users are highly concerned about how to create uniqueness constraints for the Primary Key. Therefore, the Unique data model is introduced.

    - Read-on-read combination

      The read-on-read combination of the Unique model can be replaced by the Replace mode of the Aggregate model. The internal implementation mode and data storage mode are the same.

    - Merge-on-write

      Different from the Aggregate model, the query performance of the Unique model is closer to that of the Duplicate model. Compared with the Aggregate model, the Unique model has great advantages in query performance in scenarios where primary key constraints are

required, especially in aggregation queries and queries that need to filter a large amount of data using indexes.

In a Unique table where merge-on-write is enabled, overwritten and updated data is marked and deleted during data import, and new data is written to a new file. During query, all data marked for deletion is filtered out at the file level, and the read data is the latest data. This eliminates the data aggregation process in read-time combination and supports pushdown of multiple predicates in many cases. Therefore, the performance can be greatly improved in many scenarios, especially in the case of aggregation query.

- Duplicate model

  In some multi-dimensional analysis scenarios, primary keys and data aggregation are not required. Duplicate data models can be introduced to meet such requirements.

  Different from the AGGREGATE KEY and UNIQUE KEY models, the DUPLICATE KEY model stores the data as they are and executes no aggregation. Even if there are two identical rows of data, they will both be retained. The DUPLICATE KEY in the **CREATE TABLE** statement is only used to specify based on which columns the data are sorted.

- Suggestions on data model selection

  The data model is determined when the table is created and cannot be modified. Therefore, it is important to select a proper data model.

  - The AGGREGATE KEY model aggregates data in advance, greatly reducing data scanning and calculation workload. Therefore, it is suitable for reporting query business, which has fixed schema. However, this model is not user-friendly for **count(*)** queries. In addition, because the aggregation function in Value columns is fixed, semantic correctness needs to be considered when aggregation queries using other functions are performed.

  - The Unique model ensures that the primary key is unique in scenarios where a unique primary key constraint is required. However, the query advantages brought by pre-aggregation such as ROLLUP cannot be used.
    - For users who have high performance requirements for aggregation query, you are advised to use the write-on-write combination added in version 1.2.
    - The Unique model supports only the update of an entire row. If you need to update both the unique primary key constraint and some columns (for example, importing multiple source tables to one Doris table), you can use the Aggregate model and set the aggregation type of non-primary key columns to **REPLACE_IF_NOT_NULL**.
    - Duplicate is suitable for ad-hoc query in any dimension. Although the pre-aggregation feature cannot be used, it is not restricted by the aggregation model and can make full use of the advantages of the column-store model (only related columns are read, and all key columns do not need to be read).

1.3.4.2 Relationship with Other Components

Relationship Between Doris and HDFS

Doris can import and export HDFS data and directly query HDFS data sources.

Relationship Between Doris and Hudi Components

The Doris supports direct query of the Hudi data source.

Relationship Between Doris and Spark

The Spark Doris Connector can be used to read data stored in the Doris through Spark or write data to the Doris through Spark.

Relationship Between Doris and Flink Components

You can use Flink Doris Connector to perform operations (read, insert, modify, and delete) on data stored in Doris through Flink.

Relationship Between Doris and Hive Components

Doris supports direct query of Hive data sources.

Relationship Between Doris and Kafka

Doris can import Kafka data.

1.3.5 Flink

1.3.5.1 Flink Basic Principles

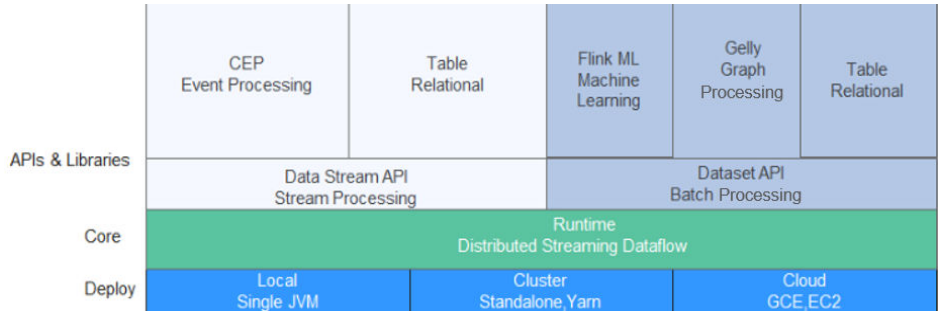
Overview

Flink is a unified computing framework that supports both batch processing and stream processing. It provides a stream data processing engine that supports data distribution and parallel computing. Flink features stream processing and is a top open source stream processing engine in the industry.

Flink provides high-concurrency pipeline data processing, millisecond-level latency, and high reliability, making it extremely suitable for low-latency data processing.

Figure 1-11 shows the technology stack of Flink.

Figure 1-11 Technology stack of Flink



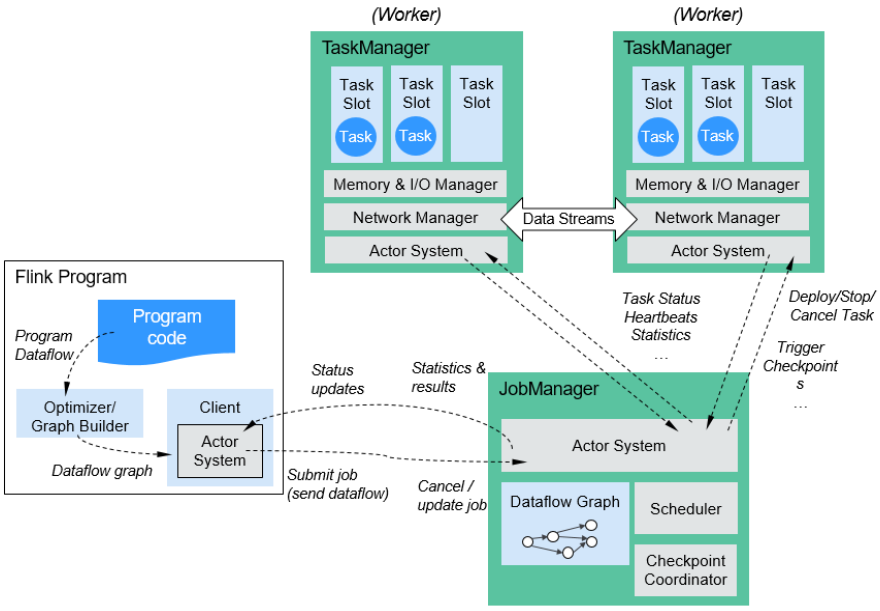
Flink provides the following features in the current version:

- DataStream
- Checkpoint
- Window
- Job Pipeline
- Configuration Table

Flink Architecture

Figure 1-12 shows the Flink architecture.

Figure 1-12 Flink architecture



As shown in the above figure, the entire Flink system consists of three parts:

- Client

  Flink client is used to submit jobs (streaming jobs) to Flink.

- TaskManager

  TaskManager is a service execution node of Flink. It executes specific tasks. A Flink system can have multiple TaskManagers. These TaskManagers are equivalent to each other.

- JobManager

  JobManager is a management node of Flink. It manages all TaskManagers and schedules tasks submitted by users to specific TaskManagers. In high-availability (HA) mode, multiple JobManagers are deployed. Among these JobManagers, one is selected as the active JobManager, and the others are standby.

Flink Principles

- **Stream & Transformation & Operator**

  A Flink program consists of two building blocks: stream and transformation.

  a. Conceptually, a stream is a (potentially never-ending) flow of data records, and a transformation is an operation that takes one or more streams as input, and produces one or more output streams as a result.

  b. When a Flink program is executed, it is mapped to a streaming dataflow. A streaming dataflow consists of a group of streams and transformation operators. Each dataflow starts with one or more source operators and ends in one or more sink operators. A dataflow resembles a directed acyclic graph (DAG).

  Figure 1-13 shows the streaming dataflow to which a Flink program is mapped.

  Figure 1-13 Example of Flink DataStream

  As shown in Figure 1-13, **FlinkKafkaConsumer** is a source operator; Map, KeyBy, TimeWindow, and Apply are transformation operators; RollingSink is a sink operator.

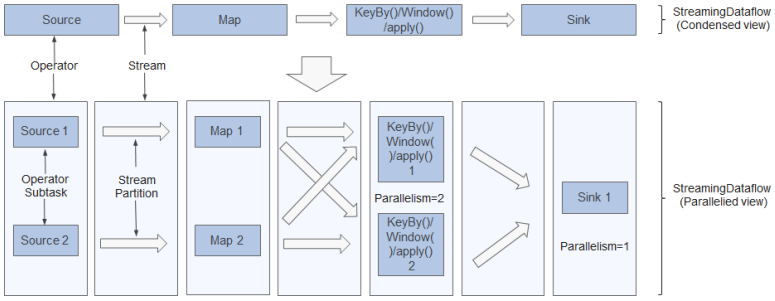
- **Pipeline Dataflow**

  Applications in Flink can be executed in parallel or distributed modes. A stream can be divided into one or more stream partitions, and an operator can be divided into multiple operator subtasks.

  The executor of streams and operators are automatically optimized based on the density of upstream and downstream operators.

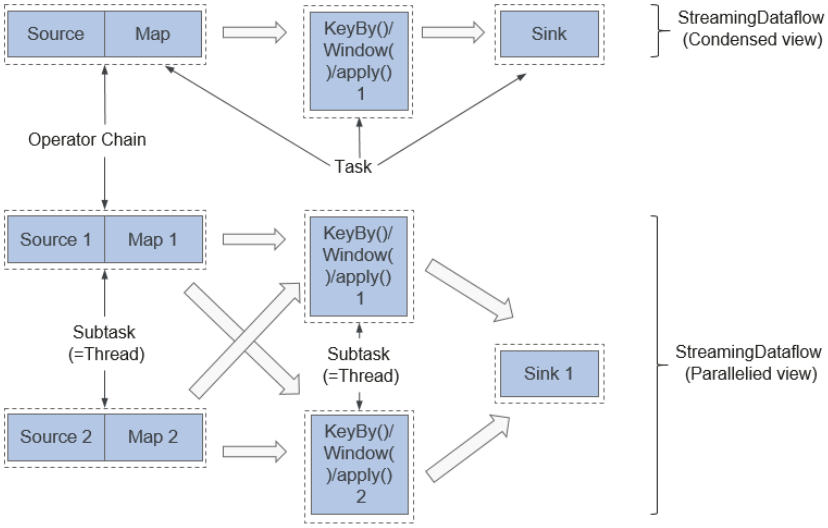
  – Operators with low density cannot be optimized. Each operator subtask is separately executed in different threads. The number of operator subtasks is the parallelism of that particular operator. The parallelism (the total number of partitions) of a stream is that of its producing operator. Different operators of the same program may have different levels of parallelism, as shown in Figure 1-14.

Figure 1-14 Operator



– Operators with high density can be optimized. Flink chains operator subtasks together into a task, that is, an operator chain. Each operator chain is executed by one thread on TaskManager, as shown in **Figure 1-15**.

Figure 1-15 Operator chain



- In the upper part of **Figure 1-15**, the condensed Source and Map operators are chained into an Operator Chain, that is, a larger operator. The Operator Chain, KeyBy, and Sink all represent an operator respectively and are connected with each other through streams. Each operator corresponds to one task during the running. Namely, there are three tasks in the upper part.
- In the lower part of **Figure 1-15**, each task, except Sink, is paralleled into two subtasks. The parallelism of the Sink operator is one.

Key Features

- Stream processing

  The real-time stream processing engine features high throughput, high performance, and low latency, which can provide processing capability within milliseconds.
- Various status management

The stream processing application needs to store the received events or intermediate result in a certain period of time for subsequent access and processing at a certain time point. Flink provides diverse features for status management, including:

- Multiple basic status types: Flink provides various states for data structures, such as ValueState, ListState, and MapState. Users can select the most efficient and suitable status type based on the service model.
- Rich State Backend: State Backend manages the status of applications and performs Checkpoint operations as required. Flink provides different State Backends. State can be stored in the memory or RocksDB, and supports the asynchronous and incremental Checkpoint mechanism.
- Exactly-once state consistency: The Checkpoint and fault recovery capabilities of Flink ensure that the application status of tasks is consistent before and after a fault occurs. Flink supports transactional output for some specific storage devices. In this way, exactly-once output can be ensured even when a fault occurs.

- Various time semantics

  Time is an important part of stream processing applications. For real-time stream processing applications, operations such as window aggregation, detection, and matching based on time semantics are very common. Flink provides various time semantics.

  - Event-time: The timestamp provided by the event is used for calculation, making it easier to process the events that arrive at a random sequence or arrive late.
  - Watermark: Flink introduces the concept of Watermark to measure the development of event time. Watermark also provides flexible assurance for balancing processing latency and data integrity. When processing event streams with Watermark, Flink provides multiple processing options if data arrives after the calculation, for example, redirecting data (side output) or updating the calculation result.
  - Processing-time and Ingestion-time are supported.
  - Highly flexible streaming window: Flink supports the time window, count window, session window, and data-driven customized window. You can customize the triggering conditions to implement the complex streaming calculation mode.

- Fault tolerance mechanism

  In a distributed system, if a single task or node breaks down or is faulty, the entire task may fail. Flink provides a task-level fault tolerance mechanism, which ensures that user data is not lost when an exception occurs in a task and can be automatically restored.

  - Checkpoint: Flink implements fault tolerance based on checkpoint. Users can customize the checkpoint policy for the entire task. When a task fails, the task can be restored to the status of the latest checkpoint and data after the snapshot is resent from the data source.
  - Savepoint: A savepoint is a consistent snapshot of application status. The savepoint mechanism is similar to that of checkpoint. However, the savepoint mechanism needs to be manually triggered. The savepoint mechanism ensures that the status information of the current stream application is not lost during task upgrade or migration, facilitating task suspension and recovery at any time point.

- Flink SQL

  Table APIs and SQL use Apache Calcite to parse, verify, and optimize queries. Table APIs and SQL can be seamlessly integrated with DataStream and DataSet APIs, and support user-defined scalar functions, aggregation functions, and table value functions. The definition of applications such as data analysis and ETL is simplified. The following code example shows how to use Flink SQL statements to define a counting application that records session times.

  ```
  SELECT userId, COUNT(*)
  FROM clicks
  GROUP BY SESSION(clicktime, INTERVAL '30' MINUTE), userId
  ```

- CEP in SQL

  Flink allows users to represent complex event processing (CEP) query results in SQL for pattern matching and evaluate event streams on Flink.

  CEP SQL is implemented through the **MATCH_RECOGNIZE** SQL syntax. The **MATCH_RECOGNIZE** clause is supported by Oracle SQL since Oracle Database 12c and is used to indicate event pattern matching in SQL. The following is an example of CEP SQL:

  ```
  SELECT T.aid, T.bid, T.cid
  FROM MyTable
    MATCH_RECOGNIZE (
      PARTITION BY userid
      ORDER BY proctime
      MEASURES
        A.id AS aid,
        B.id AS bid,
        C.id AS cid
      PATTERN (A B C)
      DEFINE
        A AS name = 'a',
        B AS name = 'b',
        C AS name = 'c'
    ) AS T
  ```

1.3.5.2 Flink HA Solution

Flink HA Solution

A Flink cluster has only one JobManager. This has the risks of single point of failures (SPOFs). There are three modes of Flink: Flink On Yarn, Flink Standalone, and Flink Local. Flink On Yarn and Flink Standalone modes are based on clusters and Flink Local mode is based on a single node. Flink On Yarn and Flink Standalone provide an HA mechanism. With such a mechanism, you can recover the JobManager from failures and thereby eliminate SPOF risks. This section describes the HA mechanism of the Flink On Yarn.

Flink supports the HA mode and job exception recovery that highly depend on ZooKeeper. If you want to enable the two functions, configure ZooKeeper in the **flink-conf.yaml** file in advance as follows:

```
high-availability: zookeeper
high-availability.zookeeper.quorum:  ZooKeeper IP address:2181
high-availability.storageDir: hdfs:///flink/recovery
```

Flink On Yarn

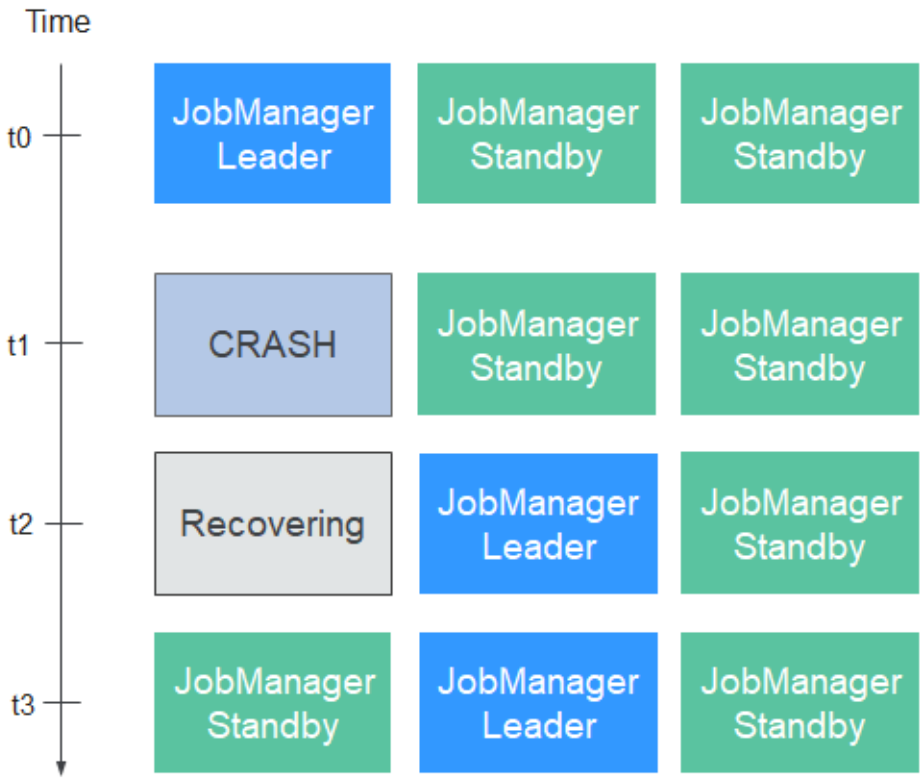
Flink JobManager and Yarn ApplicationMaster are in the same process. Yarn ResourceManager monitors ApplicationMaster. If ApplicationMaster is abnormal,

Yarn restarts it and restores all JobManager metadata from HDFS. During the recovery, existing tasks cannot run and new tasks cannot be submitted. ZooKeeper stores JobManager metadata, such as information about jobs, to be used by the new JobManager. A TaskManager failure is listened and processed by the DeathWatch mechanism of Akka on JobManager. When a TaskManager fails, a container is requested again from Yarn and a TaskManager is created.

Standalone

In the standalone mode, multiple JobManagers can be started and ZooKeeper elects one as the leader JobManager. In this mode, there is a leader JobManager and multiple standby JobManagers. If the leader JobManager fails, a standby JobManager takes over the leadership. **Figure 1-16** shows the process of a leader/standby JobManager switchover.

Figure 1-16 Switchover process



Restoring TaskManager

A TaskManager failure is listened and processed by the DeathWatch mechanism of Akka on JobManager. If the TaskManager fails, the JobManager creates a TaskManager and migrates services to the created TaskManager.

Restoring JobManager

Flink JobManager and Yarn ApplicationMaster are in the same process. Yarn ResourceManager monitors ApplicationMaster. If ApplicationMaster is abnormal, Yarn restarts it and restores all JobManager metadata from HDFS. During the recovery, existing tasks cannot run and new tasks cannot be submitted.

Restoring Jobs

If you want to restore jobs, ensure that the startup policy is configured in Flink configuration files. Supported restart policies are **fixed-delay**, **failure-rate**, and **none**. Jobs can be restored only when the policy is configured to **fixed-delay** or **failure-rate**. If the restart policy is configured to **none** and checkpoint is configured for jobs, the restart policy is automatically configured to **fixed-delay** and the value of **restart-strategy.fixed-delay.attempts** (which specifies the number of retry times) is configured to **Integer.MAX_VALUE**.

The configuration strategies are as follows:

```
restart-strategy: fixed-delay
restart-strategy.fixed-delay.attempts: 3
restart-strategy.fixed-delay.delay: 10 s
```

Jobs will be restored in the following scenarios:

- If a JobManager fails, all its jobs are stopped, and will be recovered after another JobManager is created and running.
- If a TaskManager fails, all tasks on the TaskManager are stopped, and will be started until there are available resources.
- When a task of a job fails, the job is restarted.

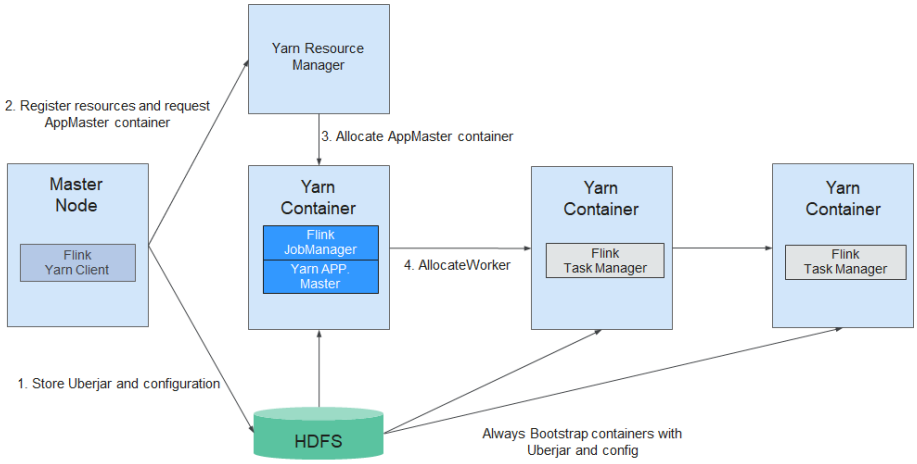
1.3.5.3 Relationship Between Flink and Other Components

Relationship Between Flink and YARN

Flink supports YARN-based cluster management mode. In this mode, Flink serves as an application of YARN and runs on YARN.

Figure 1-17 shows the YARN-based Flink cluster deployment.

Figure 1-17 YARN-based Flink cluster deployment



1. The Flink YARN Client first checks whether there are sufficient resources for starting the YARN cluster. If yes, the Flink YARN client uploads JAR files and configuration files to HDFS.
2. Flink YARN client communicates with YARN ResourceManager to request a container for starting ApplicationMaster. After all YARN NodeManagers finish downloading the JAR file and configuration files, the ApplicationMaster is started.

3. During the startup, the ApplicationMaster interacts with the YARN ResourceManager to request the container for starting a TaskManager. After the container is ready, the TaskManager process is started.
4. In the Flink YARN cluster, the ApplicationMaster and Flink JobManager are running in the same container. The ApplicationMaster informs each TaskManager of the RPC address of the JobManager. After TaskManagers are started, they register with the JobManager.
5. After all TaskManagers has registered with the JobManager, Flink starts up in the YARN cluster. Then, the Flink YARN client can submit Flink jobs to the JobManager, and Flink can perform mapping, scheduling, and computing for the jobs.

1.3.5.4 Flink Enhanced Open Source Features

1.3.5.4.1 Window

Enhanced Open Source Feature: Window

This section describes the sliding window of Flink and provides the sliding window optimization method.

Introduction to Window

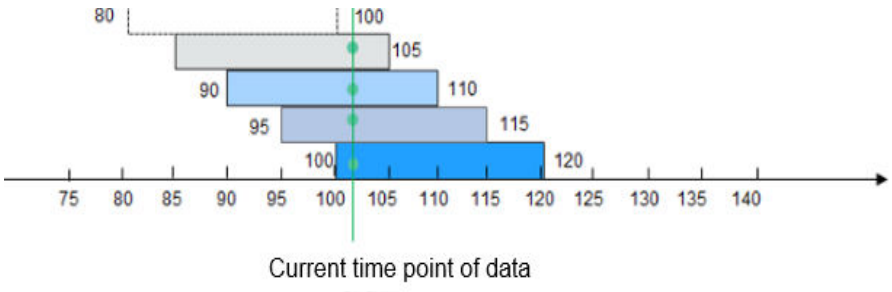
Data in a window is saved as intermediate results or original data. If you perform a sum operation (**window(SlidingEventTimeWindows.of(Time.seconds(20), Time.seconds(5))).sum**) on data in the window, only the intermediate result will be retained. If a custom window (**window(SlidingEventTimeWindows.of(Time.seconds(20), Time.seconds(5))).apply(new UDF)**) is used, all original data in the window will be saved.

If custom windows **SlidingEventTimeWindow** and **SlidingProcessingTimeWindow** are used, data is saved as multiple backups. Assume that the window is defined as follows:

```
window(SlidingEventTimeWindows.of(Time.seconds(20), Time.seconds(5))).apply(new
UDFWindowFunction)
```

If a block of data arrives, it is assigned to four different windows (20/5 = 4). That is, the data is saved as four copies in the memory. When the window size or sliding period is set to a large value, data will be saved as excessive copies, causing redundancy.

Figure 1-18 Original structure of a window



If a data block arrives at the 102nd second, it is assigned to windows [85, 105), [90, 110), [95, 115), and [100, 120).

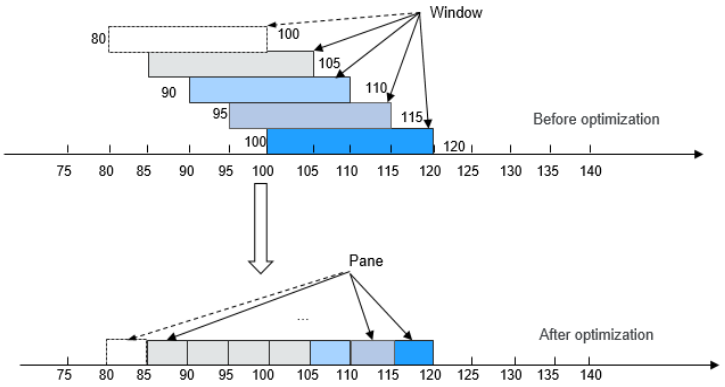
Window Optimization

As mentioned in the preceding, there are excessive data copies when original data is saved in SlidingEventTimeWindow and SlidingProcessingTimeWindow. To resolve this problem, the window that stores the original data is restructured, which optimizes the storage and greatly lowers the storage space. The window optimization scheme is as follows:

1. Use the sliding period as a unit to divide a window into different panes.

   A window consists of one or multiple panes. A pane is essentially a sliding period. For example, the sliding period (namely, the pane) of **window(SlidingEventTimeWindows.of(Time.seconds(20), Time.seconds.of(5)))** lasts for 5 seconds. If this window ranges from [100, 120), this window can be divided into panes [100, 105), [105, 110), [110, 115), and [115, 120).

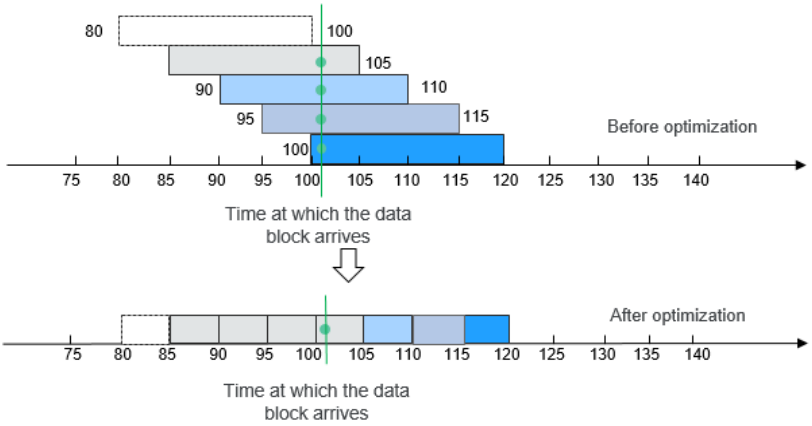
   Figure 1-19 Window optimization



2. When a data block arrives, it is not assigned to a specific window. Instead, Flink determines the pane to which the data block belongs based on the timestamp of the data block, and saves the data block into the pane.

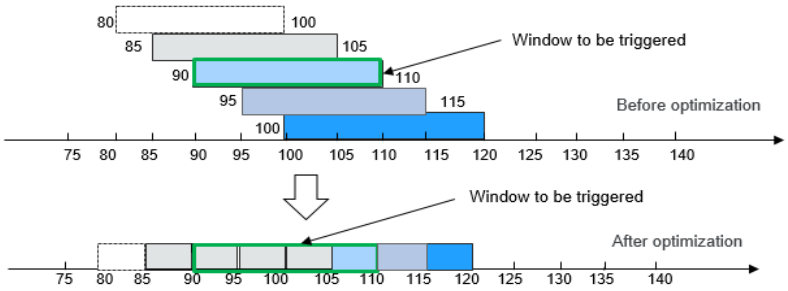
   A data block is saved only in one pane. In this case, only a data copy exists in the memory.

   Figure 1-20 Saving data in a window



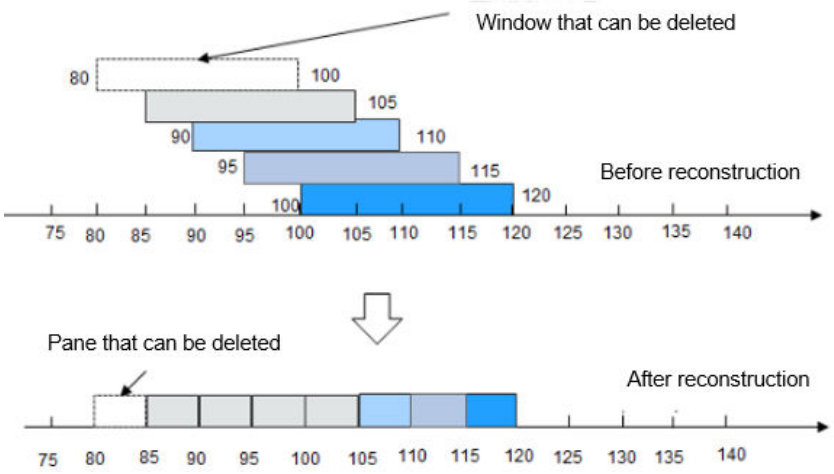
3. To trigger a window, compute all panes contained in the window, and combine all these panes into a complete window.

   Figure 1-21 Triggering a window



4. If a pane is not required, you can delete it from the memory.

   Figure 1-22 Deleting a window



After optimization, the quantity of data copies in the memory and snapshot is greatly reduced.

1.3.5.4.2 Job Pipeline

Enhanced Open Source Feature: Job Pipeline

Generally, logic code related to a service is stored in a large JAR package, which is called Fat JAR. Disadvantages of Fat JAR are as follows:

- When service logic becomes more and more complex, the size of the Fat JAR increases.
- Fat Jar makes coordination complex. Developers of all services are working with the same service logic. Even though the service logic can be divided into several modules, all modules are tightly coupled with each other. If the requirement needs to be changed, the entire flow diagram needs to be replanned.

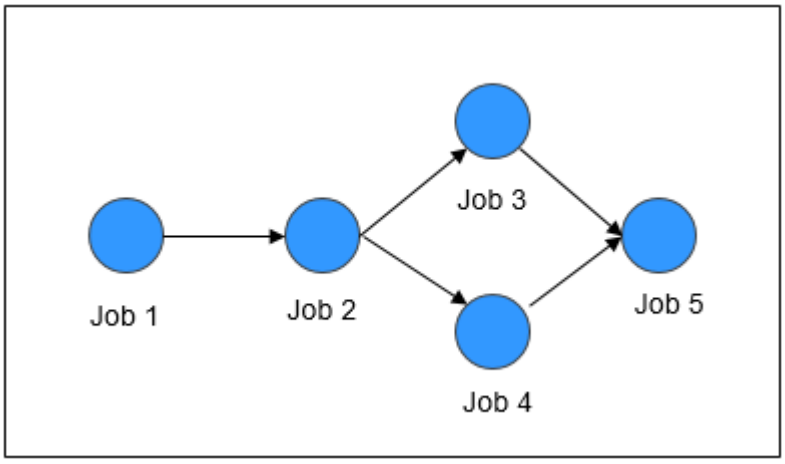
Splitting of jobs is facing the following problems:

- Data transmission between jobs can be achieved using Kafka. For example, job A transmits data to the topic A in Kafka, and then job B and job C read data from the topic A in Kafka. This solution is simple and easy to implement, but the latency is always longer than 100 ms.
- Operators are connected using the TCP protocol. In distributed environment, operators can be scheduled to any node and upstream and downstream services cannot detect the scheduling.

Job Pipeline

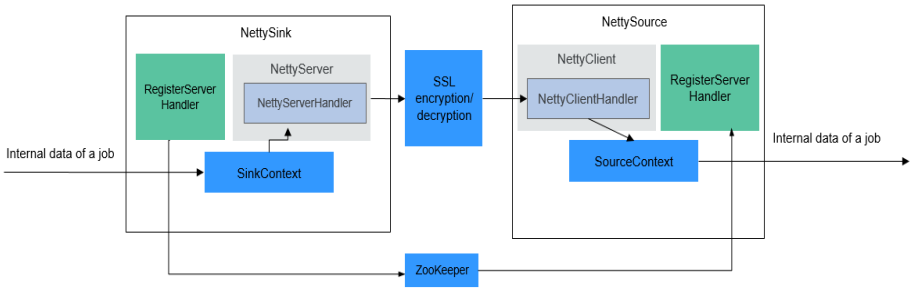
A pipeline consists of multiple Flink jobs connected through TCP. Upstream jobs can send data to downstream jobs. The flow diagram about data transmission is called a job pipeline, as shown in **Figure 1-23**.

Figure 1-23 Job pipeline



Job Pipeline Principles

Figure 1-24 Job pipeline principles



- NettySink and NettySource

  In a pipeline, upstream jobs and downstream jobs communicate with each other through Netty. The Sink operator of the upstream job works as a server and the Source operator of the downstream job works as a client. The Sink operator of the upstream job is called NettySink, and the Source operator of the downstream job is called NettySource.
- NettyServer and NettyClient

NettySink functions as the server of Netty. In NettySink, NettyServer achieves the function of a server. NettySource functions as the client of Netty. In NettySource, NettyClient achieves the function of a client.

- Publisher

  The job that sends data to downstream jobs through NettySink is called a publisher.

- Subscriber

  The job that receives data from upstream jobs through NettySource is called a subscriber.

- RegisterServer

  RegisterServer is the third-party memory that stores the IP address, port number, and concurrency information about NettyServer.

- The general outside-in architecture is as follows:
  - NettySink->NettyServer->NettyServerHandler
  - NettySource->NettyClient->NettyClientHandler

Job Pipeline Functions

- **NettySink**

  NettySink consists of the following major modules:

  - RichParallelSinkFunction

    NettySink inherits RichParallelSinkFunction and attributes of Sink operators. The RichParallelSinkFunction API implements following functions:

    - Starts the NettySink operator.
    - Runs the NettySink operator and receives data from the upstream operator.
    - Cancels the running of NettySink operators.

    Following information can be obtained using the attribute of RichParallelSinkFunction:

    - subtaskIndex about the concurrency of each NettySink operator.
    - Concurrency of the NettySink operator.

  - RegisterServerHandler

    RegisterServerHandler interacts with the component of RegisterServer and defines following APIs:

    - **start();**: Starts the RegisterServerHandler and establishes a contact with the third-party RegisterServer.
    - **createTopicNode();**: Creates a topic node.
    - **register();**: Registers information such as the IP address, port number, and concurrency to the topic node.
    - **deleteTopicNode();**: Deletes a topic node.

- **unregister();**: Deletes registration information.
- **query();**: Queries registration information.
- **isExist();**: Verifies that a specific piece of information exists.
- **shutdown();**: Disables the RegisterServerHandler and disconnects from the third-party RegisterServer.

NOTE

- RegisterServerHandler API enables ZooKeeper to work as the handler of RegisterServer. You can customize your handler as required. Information is stored in ZooKeeper in the following form:

```
Namespace
|---Topic-1
  |---parallel-1
  |---parallel-2
  |....
  |---parallel-n
|---Topic-2
  |---parallel-1
  |---parallel-2
  |....
  |---parallel-m
|...
```

- Information about NameSpace can be obtained from the following parameters of the **flink-conf.yaml** file:

```
nettyconnector.registerserver.topic.storage: /flink/nettyconnector
```

- The simple authentication and security layer (SASL) authentication between ZookeeperRegisterServerHandler and ZooKeeper is implemented through the Flink framework.
- Ensure that each job has a unique topic. Otherwise, the subscription relationship may be unclear.
- When calling **shutdown()**, ZookeeperRegisterServerHandler deletes the registration information about the current concurrency, and then attempts to delete the topic node. If the topic node is not empty, deletion will be canceled, because not all concurrency has exited.

– NettyServer

NettyServer is the core of the NettySink operator, whose main function is to create a NettyServer and receive connection requests from NettyClient. Use NettyServerHandler to send data received from upstream operators of a same job. The port number and subnet of NettyServer needs to be configured in the **flink-conf.yaml** file.

- Port range

```
nettyconnector.sinkserver.port.range: 28444-28943
```

- Subnet

```
nettyconnector.sinkserver.subnet: 10.162.222.123/24
```

NOTE

The **nettyconnector.sinkserver.subnet** parameter is set to the subnet (service IP address) of the Flink client by default. If the client and TaskManager are not in the same subnet, an error may occur. Therefore, you need to manually set this parameter to the subnet (service IP address) of TaskManager.

– NettyServerHandler

The handler enables the interaction between NettySink and subscribers. After NettySink receives messages, the handler sends these messages out. To ensure data transmission security, this channel is encrypted using SSL. The **nettyconnector.ssl.enabled** configures whether to enable SSL encryption. The SSL encryption is enabled only when **nettyconnector.ssl.enabled** is set to **true**.

- **NettySource**

  NettySource consists of the following major modules:

  – RichParallelSourceFunction

    NettySource inherits RichParallelSinkFunction and attributes of Source operators. The RichParallelSourceFunction API implements following functions:

    - Starts the NettySink operator.
    - Runs the NettySink operator, receives data from subscribers, and injects the data to jobs.
    - Cancels the running of Source operators.

    Following information can be obtained using the attribute of RichParallelSourceFunction:

    - subtaskIndex about the concurrency of each NettySource operator.
    - Concurrency of the NettySource operator.

    When the NettySource operator enters the running stage, the NettyClient status is monitored. Once abnormality occurs, NettyClient is restarted and reconnected to NettyServer, preventing data confusion.

  – RegisterServerHandler

    RegisterServerHandler of NettySource has similar function as the RegisterServerHandler of NettySink. It obtains the IP address, port number, and information of concurrent operators of each subscribed job obtained in the NettySource operator.

  – NettyClient

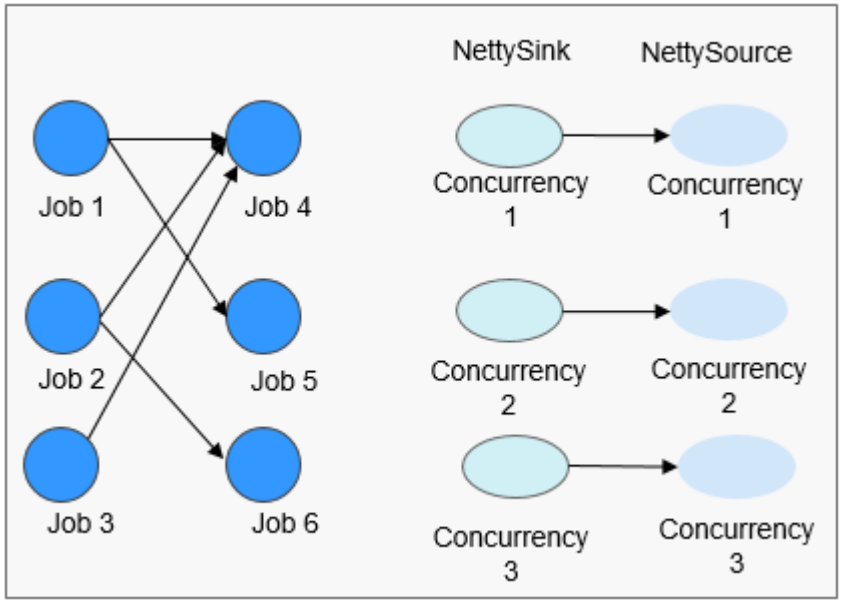
    NettyClient establishes a connection with NettyServer and uses NettyClientHandler to receive data. Each NettySource operator must have a unique name (specified by the user). NettyServer determines whether each client comes from different NettySources based on unique names. When a connection is established between NettyClient and NettyServer, NettyClient is registered with NettyServer and the NettySource name of NettyClient is transferred to NettyServer.

  – NettyClientHandler

    The NettyClientHandler enables the interaction with publishers and other operators of the job. When messages are received, NettyClientHandler transfers these messages to the job. To ensure secure data transmission, SSL encryption is enabled for the communication with NettySink. The SSL encryption is enabled only when SSL is enabled and **nettyconnector.ssl.enabled** is set to **true**.

The relationship between the jobs may be many-to-many. The concurrency between each NettySink and NettySource operator is one-to-many, as shown in **Figure 1-25**.

Figure 1-25 Relationship diagram



1.3.5.4.3 Stream SQL Join

Enhanced Open Source Feature: Stream SQL Join

Flink's Table API&SQL is an integrated query API for Scala and Java that allows the composition of queries from relational operators such as selection, filter, and join in an intuitive way.

Introduction to Stream SQL Join

SQL Join is used to query data based on the relationship between columns in two or more tables. Flink Stream SQL Join allows you to join two streaming tables and query results from them. Queries similar to the following are supported:

```
SELECT o.proctime, o.productId, o.orderId, s.proctime AS shipTime
FROM Orders AS o
JOIN Shipments AS s
ON o.orderId = s.orderId
AND o.proctime BETWEEN s.proctime AND s.proctime + INTERVAL '1' HOUR;
```

Currently, Stream SQL Join needs to be performed within a specified window. The join operation for data within the window requires at least one equi-join predicate and a join condition that bounds the time on both sides. Such a condition can be defined by two appropriate range predicates (<, <=, >=, >), a **BETWEEN** predicate, or a single equality predicate that compares the same type of time attributes (such as processing time or event time) of both input tables.

The following example will join all orders with their corresponding shipments if the order was shipped four hours after the order was received.

```
SELECT *
FROM Orders o, Shipments s
```

```
WHERE o.id = s.orderId AND
o.ordertime BETWEEN s.shiptime - INTERVAL '4' HOUR AND s.shiptime
```

NOTE

1. Stream SQL Join supports only inner join.
2. The **ON** clause should include an equal join condition.
3. Time attributes support only the processing time and event time.
4. The window condition supports only the bounded time range, for example, **o.proctime BETWEEN s.proctime - INTERVAL '1' HOUR AND s.proctime + INTERVAL '1' HOUR**. The unbounded range such as **o. proctime > s.proctime** is not supported. The **proctime** attribute of two streams must be included. **o.proctime BETWEEN proctime () AND proctime () + 1** is not supported.

1.3.5.4.4 Flink CEP in SQL

Flink CEP in SQL

Flink allows users to represent complex event processing (CEP) query results in SQL for pattern matching and evaluate event streams on Flink engines.

SQL Query Syntax

CEP SQL is implemented through the **MATCH_RECOGNIZE** SQL syntax. The **MATCH_RECOGNIZE** clause is supported by Oracle SQL since Oracle Database 12c and is used to indicate event pattern matching in SQL. Apache Calcite also supports the **MATCH_RECOGNIZE** clause.

Flink uses Calcite to analyze SQL query results. Therefore, this operation complies with the Apache Calcite syntax.

```
MATCH_RECOGNIZE (
    [ PARTITION BY expression [, expression ]* ]
    [ ORDER BY orderItem [, orderItem ]* ]
    [ MEASURES measureColumn [, measureColumn ]* ]
    [ ONE ROW PER MATCH | ALL ROWS PER MATCH ]
    [ AFTER MATCH
          ( SKIP TO NEXT ROW
          | SKIP PAST LAST ROW
          | SKIP TO FIRST variable
          | SKIP TO LAST variable
          | SKIP TO variable )
    ]
    PATTERN ( pattern )
    [ WITHIN intervalLiteral ]
    [ SUBSET subsetItem [, subsetItem ]* ]
    DEFINE variable AS condition [, variable AS condition ]*
    )
```

The syntax elements of the **MATCH_RECOGNIZE** clause are defined as follows:

(Optional) **-PARTITION BY**: defines partition columns. This clause is optional. If this parameter is not defined, the parallelism 1 is used.

(Optional) **-ORDER BY**: defines the sequence of events in a data flow. The **ORDER BY** clause is optional. If it is ignored, non-deterministic sorting is used. Since the order of events is important in pattern matching, this clause should be specified in most cases.

(Optional) **-MEASURES**: specifies the attribute value of the successfully matched event.

(Optional) **-ONE ROW PER MATCH | ALL ROWS PER MATCH**: defines how to output the result. **ONE ROW PER MATCH** indicates that only one row is output for each matching. **ALL ROWS PER MATCH** indicates that one row is output for each matching event.

(Optional) **-AFTER MATCH**: specifies the start position for processing after the next pattern is successfully matched.

-PATTERN: defines the matching pattern as a regular expression. The following operators can be used in the **PATTERN** clause: join operators, quantifier operators (*, +, ?, {n}, {n,}, {n,m}, and {,m}), branch operators (vertical bar |), and differential operators ('{- -}').

(Optional) **-WITHIN**: outputs a pattern clause match only when the match occurs within the specified time.

(Optional) **-SUBSET**: combines one or more associated variables defined in the **DEFINE** clause.

-DEFINE: specifies the Boolean condition, which defines the variables used in the **PATTERN** clause.

In addition, the **MATCH_RECOGNIZE** clause supports the following functions:

-MATCH_NUMBER(): Used in the **MEASURES** clause to allocate the same number to each row that is successfully matched.

-CLASSIFIER(): Used in the **MEASURES** clause to indicate the mapping between matched rows and variables.

-FIRST() and **LAST()**: Used in the **MEASURES** clause to return the value of the expression evaluated in the first or last row of the row set mapped to the schema variable.

-NEXT() and **PREV()**: Used in the **DEFINE** clause to evaluate an expression using the previous or next row in a partition.

-RUNNING and **FINAL** keywords: Used to determine the semantics required for aggregation. **RUNNING** can be used in the **MEASURES** and **DEFINE** clauses, whereas **FINAL** can be used only in the **MEASURES** clause.

- Aggregate functions (**COUNT**, **SUM**, **AVG**, **MAX**, **MIN**): Used in the **MEASURES** and **DEFINE** clauses.

Query Example

The following query finds the V-shaped pattern in the stock price data flow.

```
SELECT *
   FROM MyTable
   MATCH_RECOGNIZE (
     ORDER BY rowtime
     MEASURES
       STRT.name as s_name,
       LAST(DOWN.name) as down_name,
       LAST(UP.name) as up_name
     ONE ROW PER MATCH
     PATTERN (STRT DOWN+ UP+)
     DEFINE
       DOWN AS DOWN.v < PREV(DOWN.v),
       UP AS UP.v > PREV(UP.v)
   )
```

In the following query, the aggregate function **AVG** is used in the **MEASURES** clause of **SUBSET E** consisting of variables related to A and C.

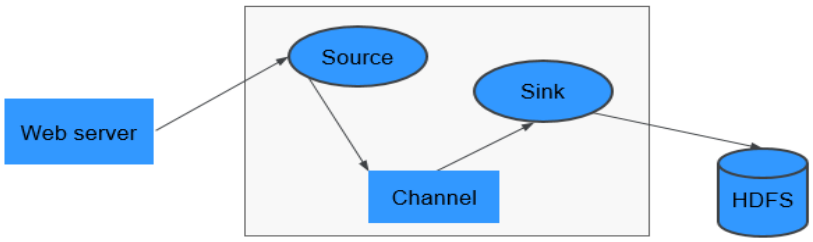
```
SELECT *
   FROM Ticker
   MATCH_RECOGNIZE (
     MEASURES
       AVG(E.price) AS avgPrice
     ONE ROW PER MATCH
     AFTER MATCH SKIP PAST LAST ROW
     PATTERN (A B+ C)
     SUBSET E = (A,C)
     DEFINE
       A AS A.price < 30,
       B AS B.price < 20,
       C AS C.price < 30
   )
```

1.3.6 Flume

1.3.6.1 Flume Basic Principles

Flume is a distributed, reliable, and HA system that supports massive log collection, aggregation, and transmission. Flume supports customization of various data senders in the log system for data collection. In addition, Flume can roughly process data and write data to various data receivers (customizable). A Flume-NG is a branch of Flume. It is simple, small, and easy to deploy. The following figure shows the basic architecture of the Flume-NG.

Figure 1-26 Flume-NG architecture



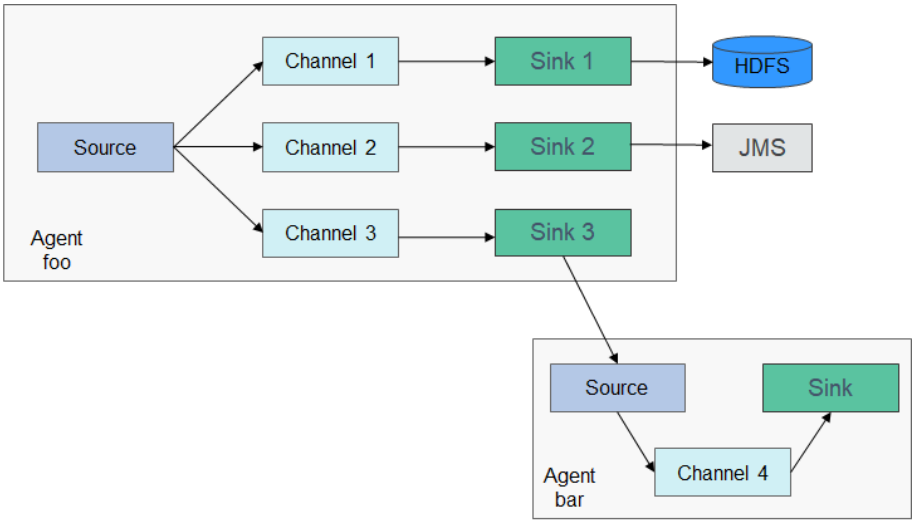
A Flume-NG consists of agents. Each agent consists of three components (source, channel, and sink). A source is used for receiving data. A channel is used for transmitting data. A sink is used for sending data to the next end.

Table 1-5 Module description

Module	Description
Source	A source receives data or generates data by using a special mechanism, and places the data in batches in one or more channels. The source can work in data-driven or polling mode. Typical source types are as follows: ● Sources that are integrated with the system, such as Syslog and Netcat ● Sources that automatically generate events, such as Exec and SEQ ● IPC sources that are used for communication between agents, such as Avro A source must be associated with at least one channel.
Channel	A channel is used to buffer data between a source and a sink. The channel caches data from the source and deletes that data after the sink sends the data to the next-hop channel or final destination. Different channels provide different persistence levels. ● Memory channel: non-persistency ● File channel: Write-Ahead Logging (WAL)-based persistence ● JDBC channel: persistency implemented based on the embedded database The channel supports the transaction feature to ensure simple sequential operations. A channel can work with sources and sinks of any quantity.
Sink	A sink sends data to the next-hop channel or final destination. Once completed, the transmitted data is removed from the channel. Typical sink types are as follows: ● Sinks that send storage data to the final destination, such as HDFS and HBase ● Sinks that are consumed automatically, such as Null Sink ● IPC sinks used for communication between Agents, such as Avro A sink must be associated with a specific channel.

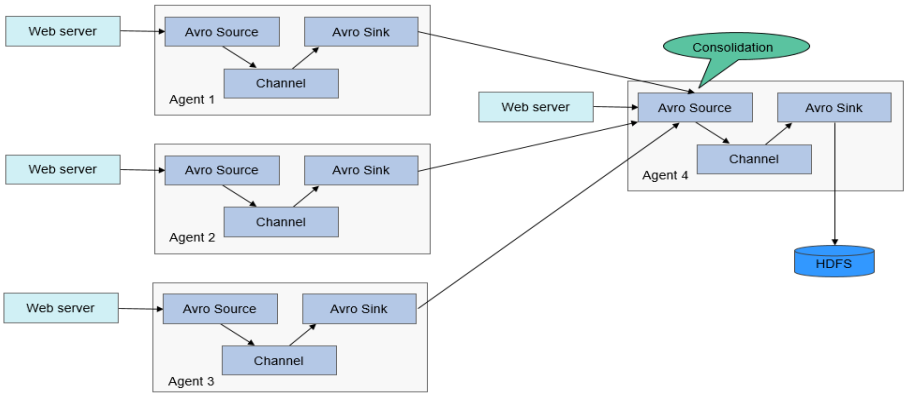
As shown in **Figure 1-27**, a Flume client can have multiple sources, channels, and sinks.

Figure 1-27 Flume structure



The reliability of Flume depends on transaction switchovers between agents. If the next agent breaks down, the channel stores data persistently and transmits data until the agent recovers. The availability of Flume depends on the built-in load balancing and failover mechanisms. Both the channel and agent can be configured with multiple entities between which they can use load balancing policies. Each agent is a Java Virtual Machine (JVM) process. A server can have multiple agents. Collection nodes (for example, Agents 1, 2, 3) process logs. Aggregation nodes (for example, Agent 4) write the logs into HDFS. The agent of each collection node can select multiple aggregation nodes for load balancing.

Figure 1-28 Flume cascading

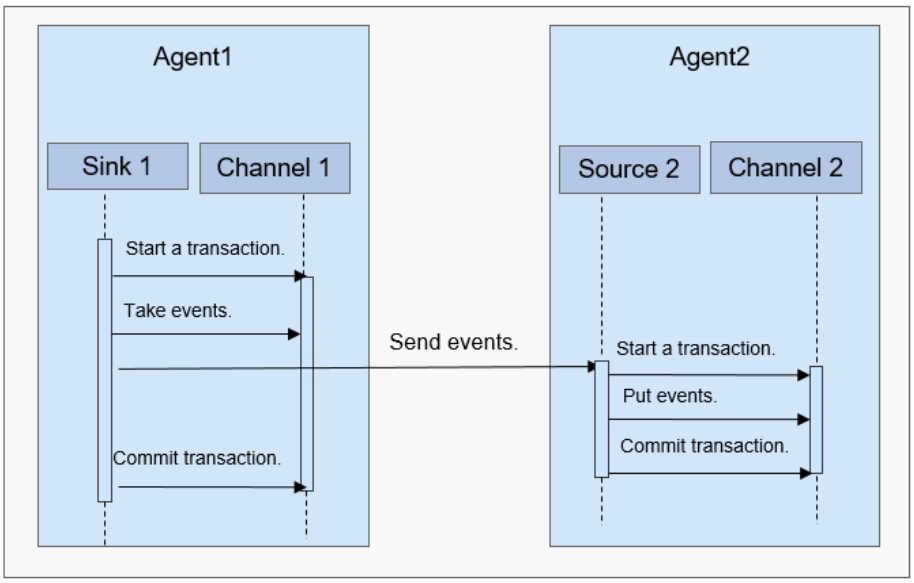


Principle

Reliability Between Agents

Figure 1-29 shows the data exchange between agents.

Figure 1-29 Data transmission process



1. Flume ensures reliable data transmission based on transactions. When data flows from one agent to another agent, the two transactions take effect. The sink of Agent 1 (agent that sends a message) needs to obtain a message from a channel and sends the message to Agent 2 (agent that receives the message). If Agent 2 receives and successfully processes the message, Agent 1 will submit a transaction, indicating a successful and reliable data transmission.
2. When Agent 2 receives the message sent by Agent 1 and starts a new transaction, after the data is processed successfully (written to a channel), Agent 2 submits the transaction and sends a success response to Agent 1.
3. Before a commit operation, if the data transmission fails, the last transcription starts and retransmits the data that fails to be transmitted last time. The commit operation has written the transaction into a disk. Therefore, the last transaction can continue after the process fails and restores.

1.3.6.2 Relationship Between Flume and Other Components

Relationship Between Flume and HDFS

If HDFS is configured as the Flume sink, HDFS functions as the final data storage system of Flume. Flume installs, configures, and writes all transmitted data into HDFS.

Relationship Between Flume and HBase

If HBase is configured as the Flume sink, HBase functions as the final data storage system of Flume. Flume writes all transmitted data into HBase based on configurations.

1.3.6.3 Flume Enhanced Open Source Features

Flume Enhanced Open Source Features

- Improving transmission speed: Multiple lines instead of only one line of data can be specified as an event. This improves the efficiency of code execution and reduces the times of disk writes.
- Transferring ultra-large binary files: According to the current memory usage, Flume automatically adjusts the memory used for transferring ultra-large binary files to prevent out-of-memory.
- Supporting the customization of preparations before and after transmission: Flume supports customized scripts to be run before or after transmission for making preparations.
- Managing client alarms: Flume receives Flume client alarms through MonitorServer and reports the alarms to the alarm management center on MRS Manager.

1.3.7 FTP-Server

1.3.7.1 FTP-Server Basic Principles

Overview

FTP-Server is a pure Java File Transfer Protocol (FTP) service based on the existing open FTP protocol. FTP-Server supports FTP and FTP over SSL (FTPS). Each FTP-Server service supports port and passive data transmission modes. You can perform operations, such as uploading or downloading files, viewing, creating, or deleting directories, and modifying file access permissions, on HDFS through an FTP client.

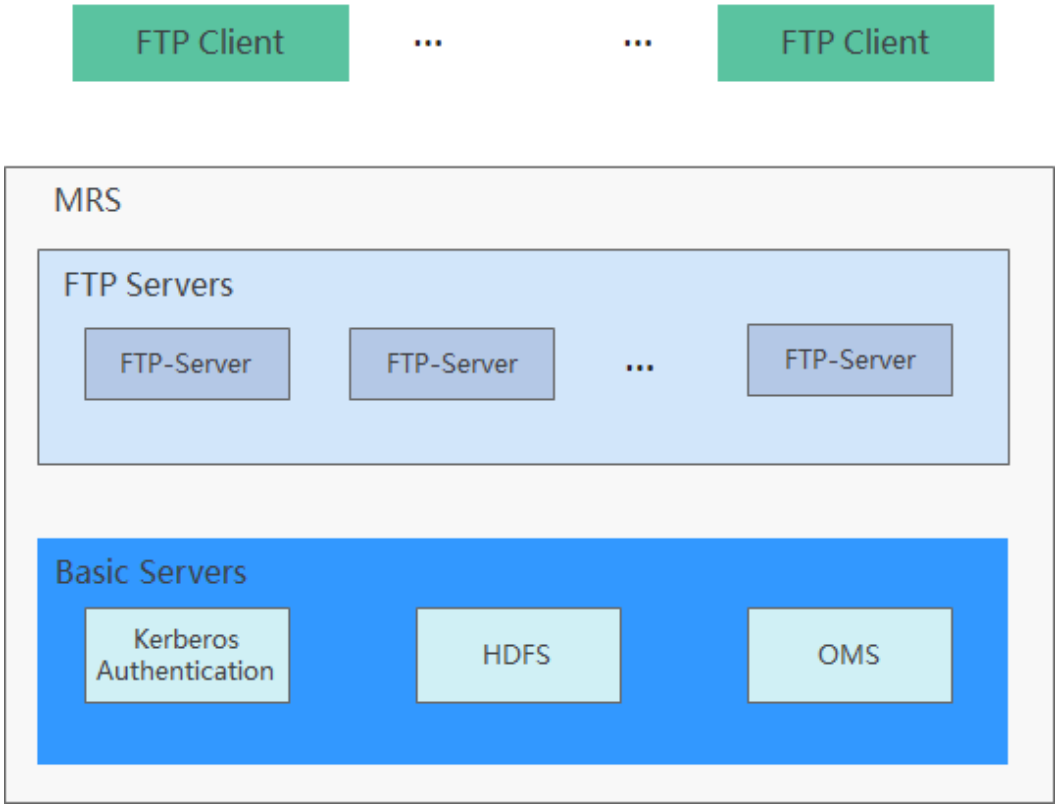
- Supports FTPS. FTPS-based data transmission is encrypted to ensure security. FTP has security risks. It is recommended that FTPS be used.
- Supports port and passive data transmission modes.
- Performs user authentication by using the Kerberos authentication service provided by a cluster.

FTP-Server structure

The FTP-Server service consists of multiple FTP-Server or FTPS-Server processes, as shown in **Figure 1-30**.

The FTP-Server service can be deployed on multiple nodes. Each node has only one FTP-Server instance, and each instance has only one FTP-Server process.

Figure 1-30 FTP-Server structure



FTP Client

The FTP client is used to access the FTP server to upload and download data. The FTP client is integrated into service applications.

FTP Server

The FTP server provides standard FTP APIs externally for FTP clients to access the HDFS system. The FTP server provides most of the FTP commands.

The basic MRS services implement underlying services of FTP servers. That is, the Kerberos security authentication service implements user management, the HDFS service implements data storage, and the OMS service implements service configuration.

Basic Servers

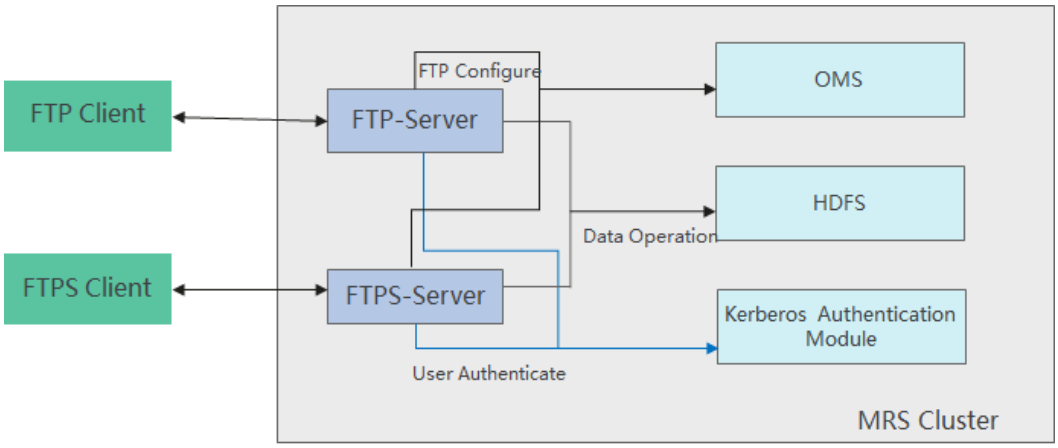
The FTP server provides the following basic services:

- Kerberos security service: supports FTP user management and user login.
- HDFS: implements data storage.
- OMS: configures FTP service parameters and enables or disables FTP services.

Principle

Figure 1-31 shows the FTP-Server data access process.

Figure 1-31 FTP-Server data access process



1. An FTP client connects to the FTP server using the FTP service IP address and port number.
2. The FTP server uses the information to perform user authentication on the Kerberos module.
3. After the authentication succeeds, the FTP server accesses HDFS and returns the file information to the client.
4. The FTP client uses the standard FTP to upload and download files and manage HDFS file directories.

Security

FTP communication is not encrypted, so that the content, username, password, and transmission data are easily stolen. Therefore, FTPS is recommended to be used in untrusted networks. MRS provides FTP-Server to support basic enterprise and financial applications. FTPS allows data to be encrypted during transmission, effectively preventing information leakage. When the client uses FTPS, only the implicit **FTP over TLS** encryption mode is supported.

The FTP-Server process of FTP is disabled by default. The administrator can enable it on the FTP service configuration window. A connection can be created (using the business IP address) only after the service is restarted.

Each node supports 16 FTP/FTPS (user or client) connections by default. To satisfy performance requirements, FTPS is recommended to be used with the command channel encrypted but the data channel not encrypted.

1.3.7.2 Relationship with Components

Relationship Between FTP-Server and HDFS

HDFS is the storage file system of FTP-Server. All the data uploaded by users is stored on related directories on HDFS. Users perform operations on the files in HDFS by using FTP commands.

Relationship Between FTP-Server and Kerberos

Kerberos Authentication Module is the authentication module of FTP-Server. FTP-Client needs to send the username and password to FTP-Server before connecting

to FTP-Server. After receiving the username and password, FTP-Server uses the Kerberos service to check whether the password is correct and whether the user has the rights to access FTP-Server.

1.3.7.3 FTP-Server Enhanced Open Source Features

Enhanced Open Source Feature: Kerberos Authentication

Apache FTP Server authentication records usernames and passwords in files or databases. In a distributed system, this storage mode has certain defects. The file storage mode is not applicable for distributed systems, while the database storage mode is quite different from user management in HDFS. Therefore, MRS uses the Kerberos service in the cluster for authentication, seamlessly integrating user management, cluster user management, and HDFS user management.

Enhanced Open Source Feature: FTP-based File Transfer to the HDFS File System

As the storage file system of FTP-Server, HDFS stores all data of FTP-Server.

1.3.8 Guardian

Guardian Basic Principles

Guardian is a service that provides temporary authentication credentials for services such as HDFS, Hive, Spark, HBase, Loader and HetuEngine to access OBS in decoupled storage and compute scenarios. The Guardian component needs to be installed only when OBS is connected. Typical features of Guardian include:

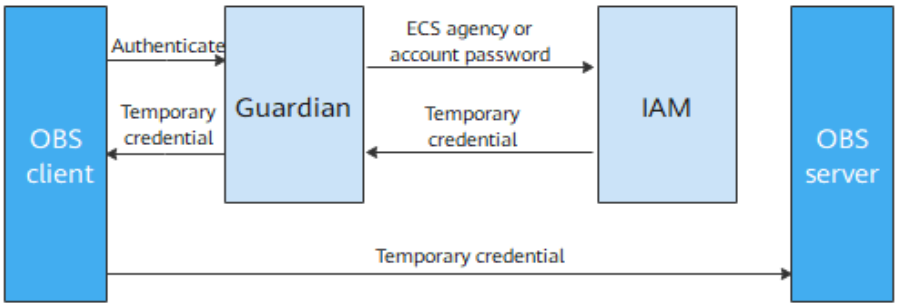
- Provides the capability of obtaining temporary authentication credentials for accessing OBS.
- Provides fine-grained permission control for accessing OBS.
- Provides the unified cache refreshing capability for temporary authentication credentials used to access OBS.

The Guardian server provides functions for the TokenServer role. TokenServer supports multi-instance deployment. Each instance can have the same functions. A single point of failure (SPOF) does not affect service functions. In addition, the Guardian server provides RPC and HTTPS interfaces to obtain temporary authentication credentials for accessing OBS.

Guardian Architecture

Figure 1-32 shows the basic architecture of Guardian.

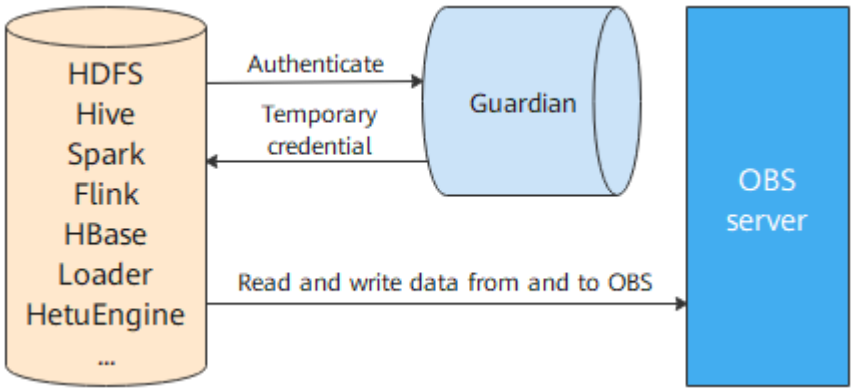
Figure 1-32 Guardian architecture



Relationships Between Guardian and Other Components

Before accessing OBS, HDFS, Hive, Spark, Flink, HBase, Loader, and HetuEngine access Guardian to obtain temporary credentials for the access. Guardian generates a temporary credential with fine-grained authentication content based on the IAM access request of the current login user and returns the credential to the component. The component uses the credential to access OBS. OBS determines whether the current user has the access permission based on the credential.

Figure 1-33 Relationships between Guardian and other components



1.3.9 HBase

1.3.9.1 HBase Basic Principles

HBase undertakes data storage. HBase is an open source, column-oriented, distributed storage system that is suitable for storing massive amounts of unstructured or semi-structured data. It features high reliability, high performance, and flexible scalability, and supports real-time data read/write.

Typical features of a table stored in HBase are as follows:

- Big table (BigTable): One table contains hundred millions of rows and millions of columns.
- Column-oriented: Column-oriented storage, retrieval, and permission control

- Sparse: Null columns in the table do not occupy any storage space.

MRS HBase supports decoupled storage and compute to allow data to be stored in low-cost cloud storage services (for example, OBS) and allow data to be backed up across AZs. Furthermore, MRS HBase supports secondary indexing to allow indexes to be created for column values so that data can be filtered by column using native HBase APIs.

HBase Architecture

An HBase cluster consists of active and standby HMaster processes and multiple RegionServer processes.

Figure 1-34 HBase architecture

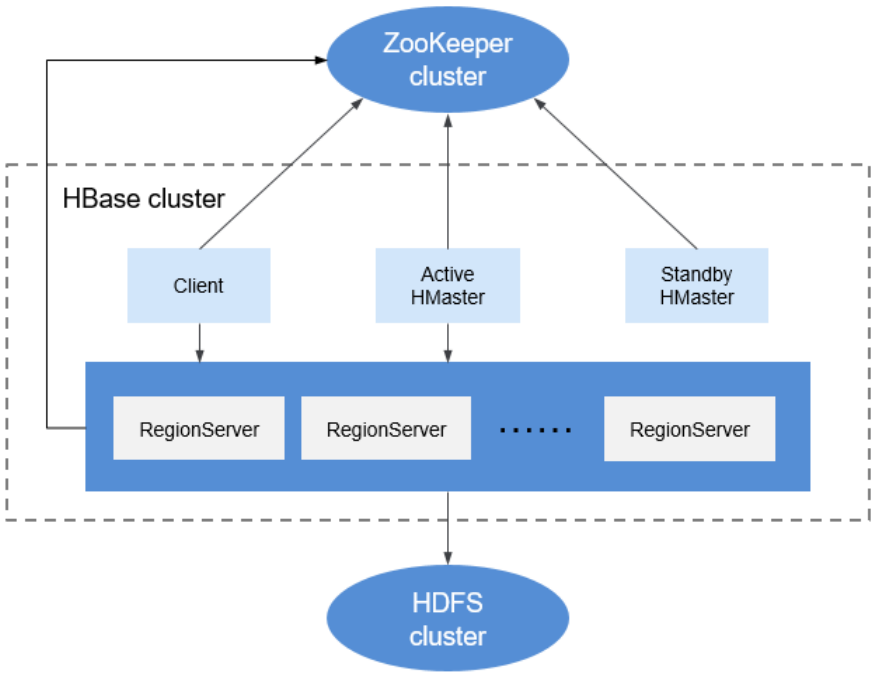


Table 1-6 Module description

Module	Description
Master	Master is also called HMaster. In HA mode, HMaster consists of an active HMaster and a standby HMaster. • Active Master: manages RegionServer in HBase, including the creation, deletion, modification, and query of a table, balances the load of RegionServer, adjusts the distribution of Region, splits Region and distributes Region after it is split, and migrates Region after RegionServer expires. • Standby Master: takes over services when the active HMaster is faulty. The original active HMaster demotes to the standby HMaster after the fault is rectified.

Module	Description
Client	Client communicates with Master for management and with RegionServer for data protection by using the Remote Procedure Call (RPC) mechanism of HBase.
RegionServer	RegionServer provides read and write services of table data as a data processing and computing unit in HBase. RegionServer is deployed with DataNodes of HDFS clusters to store data.
ZooKeeper cluster	ZooKeeper provides distributed coordination services for processes in HBase clusters. Each RegionServer is registered with ZooKeeper so that the active Master can obtain the health status of each RegionServer.
HDFS cluster	HDFS provides highly reliable file storage services for HBase. All HBase data is stored in the HDFS.

HBase Principles

- **HBase Data Model**

  HBase stores data in tables, as shown in **Figure 1-35**. Data in a table is divided into multiple Regions, which are allocated by Master to RegionServers for management.

  Each Region contains data within a RowKey range. An HBase data table contains only one Region at first. As the number of data increases and reaches the upper limit of the Region capacity, the Region is split into two Regions. You can define the RowKey range of a Region when creating a table or define the Region size in the configuration file.

  Figure 1-35 HBase data model

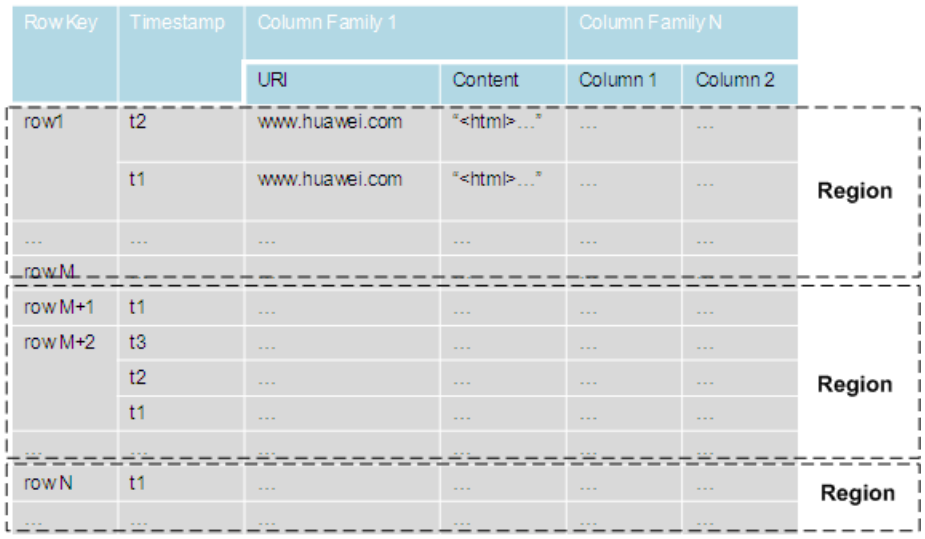

Table 1-7 Concepts

Module	Description
RowKey	Similar to the primary key in a relationship table, which is the unique ID of the data in each row. A RowKey can be a string, integer, or binary string. All records are stored after being sorted by RowKey.
Timestamp	The timestamp of a data operation. Data can be specified with different versions by time stamp. Data of different versions in each cell is stored by time in descending order.
Cell	Minimum storage unit of HBase, consisting of keys and values. A key consists of six fields, namely row, column family, column qualifier, timestamp, type, and MVCC version. Values are the binary data objects.
Column Family	One or multiple horizontal column families form a table. A column family can consist of multiple random columns. A column is a label under a column family, which can be added as required when data is written. The column family supports dynamic expansion so the number and type of columns do not need to be predefined. Columns of a table in HBase are sparsely distributed. The number and type of columns in different rows can be different. Each column family has the independent time to live (TTL). You can lock the row only. Operations on the row in a column family are the same as those on other rows.
Column	Similar to traditional databases, HBase tables also use columns to store data of the same type.

- **RegionServer Data Storage**

  RegionServer manages the regions allocated by HMaster. **Figure 1-36** shows the data storage structure of RegionServer.

Figure 1-36 RegionServer data storage structure

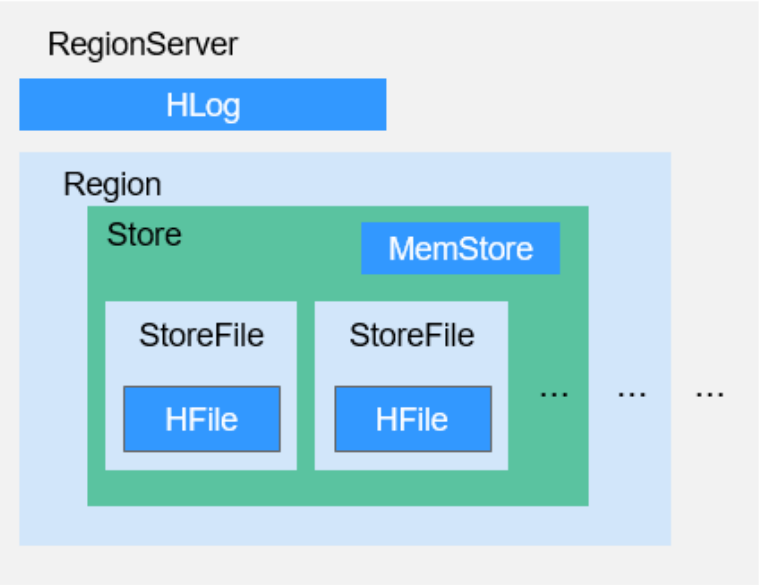

Table 1-8 lists each component of Region described in Figure 1-36.

Table 1-8 Region structure description

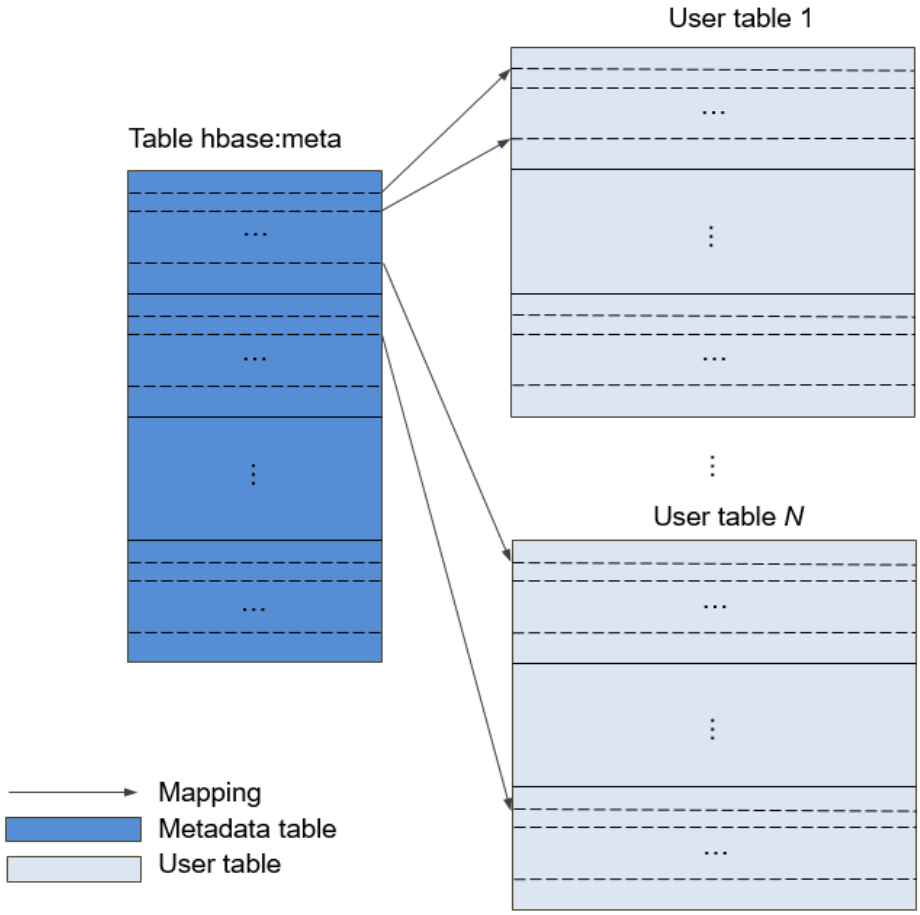
Module	Description
Store	A Region consists of one or multiple Stores. Each Store maps a column family in Figure 1-35.
MemStore	A Store contains one MemStore. The MemStore caches data inserted to a Region by the client. When the MemStore capacity reaches the upper limit, RegionServer flushes data in MemStore to the HDFS.
StoreFile	The data flushed to the HDFS is stored as a StoreFile in the HDFS. As more data is inserted, multiple StoreFiles are generated in a Store. When the number of StoreFiles reaches the upper limit, RegionServer merges multiple StoreFiles into a big StoreFile.
HFile	HFile defines the storage format of StoreFiles in a file system. HFile is the underlying implementation of StoreFile.
HLog	HLogs prevent data loss when RegionServer is faulty. Multiple Regions in a RegionServer share the same HLog.

- **Metadata Table**

  The metadata table is a special HBase table, which is used by the client to locate a region. Metadata table includes **hbase:meta** table to record region information of user tables, such as the region location and start and end RowKey.

Figure 1-37 shows the mapping relationship between metadata tables and user tables.

Figure 1-37 Mapping relationships between metadata tables and user tables



- **Data Operation Process**

  Figure 1-38 shows the HBase data operation process.

  Figure 1-38 Data processing

  a. When you add, delete, modify, and query HBase data, the HBase client first connects to ZooKeeper to obtain information about the RegionServer

where the **hbase:meta** table is located. If you modify the namespace, such as creating and deleting a table, you need to access HMaster to update the meta information.

b. The HBase client connects to the RegionServer where the region of the **hbase:meta** table is located and obtains the RegionServer location where the region of the user table resides.

c. Then the HBase client connects to the RegionServer where the region of the user table is located and issues a data operation command to the RegionServer. The RegionServer executes the command.

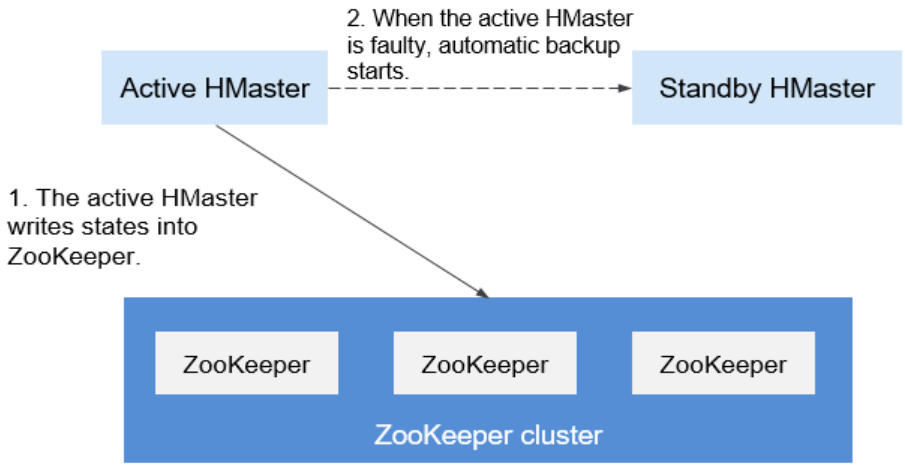
To improve data processing efficiency, the HBase client caches region information of the **hbase:meta** table and user table. When an application initiates a second data operation, the HBase client queries the region information from the memory. If no match is found in the memory, the HBase client performs the preceding operations to obtain region information.

1.3.9.2 HBase HA Solution

HBase HA

HMaster in HBase allocates Regions. When one RegionServer service is stopped, HMaster migrates the corresponding Region to another RegionServer. The HMaster HA feature is brought in to prevent HBase functions from being affected by the HMaster single point of failure (SPOF).

Figure 1-39 HMaster HA implementation architecture



The HMaster HA architecture is implemented by creating the ephemeral ZooKeeper node in a ZooKeeper cluster.

Upon startup, HMaster nodes try to create a master znode in the ZooKeeper cluster. The HMaster node that creates the master znode first becomes the active HMaster, and the other is the standby HMaster.

It will add watch events to the master node. If the service on the active HMaster is stopped, the active HMaster disconnects from the ZooKeeper cluster. After the session expires, the active HMaster disappears. The standby HMaster detects the

disappearance of the active HMaster through watch events and creates a master node to make itself be the active one. Then, the active/standby switchover completes. If the failed node detects existence of the master node after being restarted, it enters the standby state and adds watch events to the master node.

When the client accesses the HBase, it first obtains the HMaster's address based on the master node information on the ZooKeeper and then establishes a connection to the active HMaster.

1.3.9.3 Relationship with Other Components

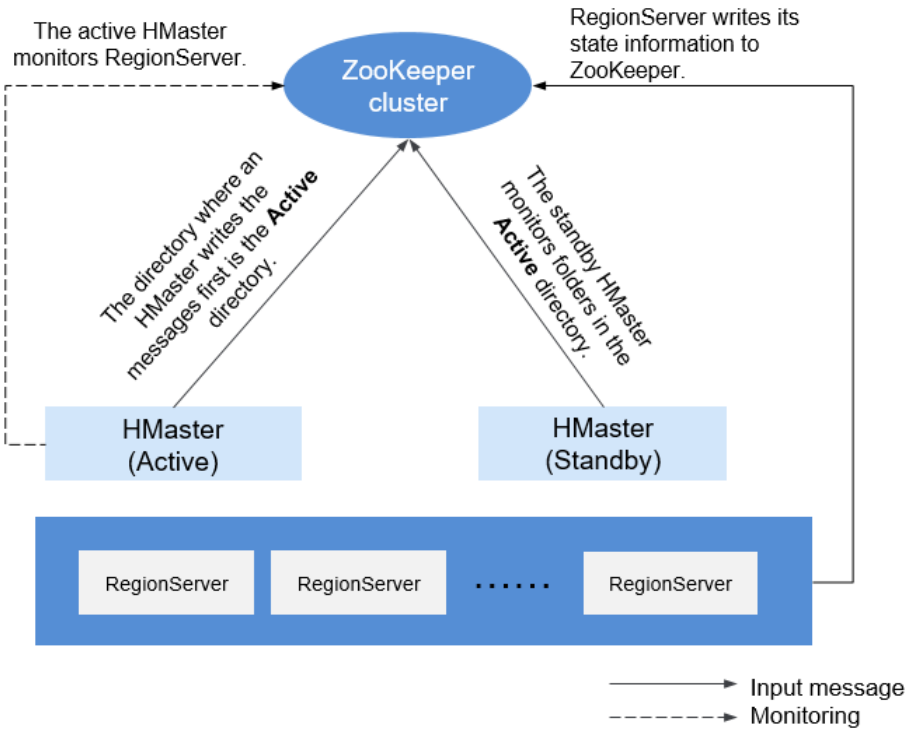
Relationship Between HDFS and HBase

HDFS is the subproject of Apache Hadoop. HBase uses the Hadoop Distributed File System (HDFS) as the file storage system. HBase is located in structured storage layer. The HDFS provides highly reliable support for lower-layer storage of HBase. All the data files of HBase can be stored in the HDFS, except some log files generated by HBase.

Relationship Between ZooKeeper and HBase

Figure 1-40 describes the relationship between ZooKeeper and HBase.

Figure 1-40 Relationship between ZooKeeper and HBase



1. HRegionServer registers itself to ZooKeeper in Ephemeral node. ZooKeeper stores the HBase information, including the HBase metadata and HMaster addresses.
2. HMaster detects the health status of each HRegionServer using ZooKeeper, and monitors them.

3. HBase can deploy multiple HMasters (like HDFS NameNode). When the active HMatser node is faulty, the standby HMaster node obtains the state information of the entire cluster using ZooKeeper, which means that HBase single point faults can be avoided using ZooKeeper.

1.3.9.4 HBase Enhanced Open Source Features

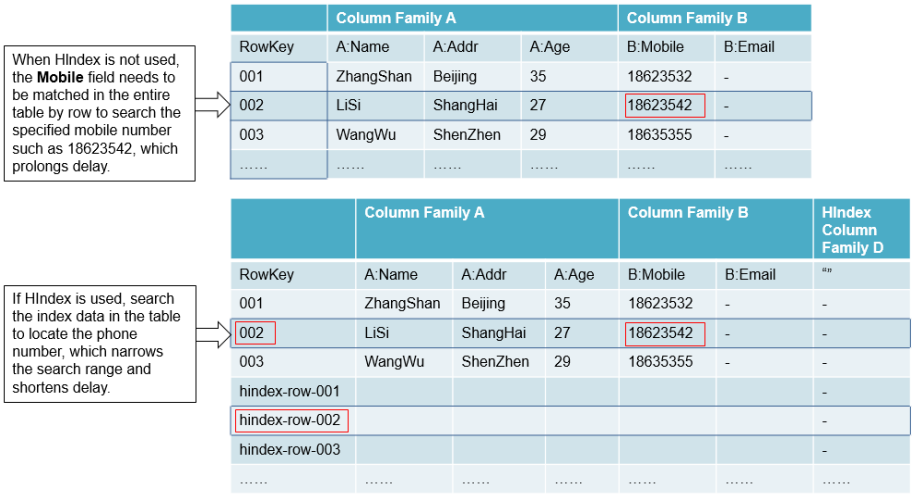
HIndex

HBase is a distributed storage database of the Key-Value type. Data of a table is sorted in the alphabetic order based on row keys. If you query data based on a specified row key or scan data in the scale of a specified row key, HBase can quickly locate the target data, enhancing the efficiency.

However, in most actual scenarios, you need to query the data of which the column value is *XXX*. HBase provides the Filter feature to query data with a specific column value. All data is scanned in the order of row keys, and then the data is matched with the specific column value until the required data is found. The Filter feature scans some unnecessary data to obtain the only required data. Therefore, the Filter feature cannot meet the requirements of frequent queries with high performance standards.

HBase HIndex is designed to address these issues. HBase HIndex enables HBase to query data based on specific column values.

Figure 1-41 HIndex



- Rolling upgrade is not supported for index data.
- Restrictions of combined indexes:
  - All columns involved in combined indexes must be entered or deleted in a single mutation. Otherwise, inconsistency will occur.

    Index: **IDX1=>cf1:[q1->datatype],[q2];cf2:[q2->datatype]**

    Correct write operations:

    ```
    Put put = new Put(Bytes.toBytes("row"));
    put.addColumn(Bytes.toBytes("cf1"), Bytes.toBytes("q1"), Bytes.toBytes("valueA"));
    put.addColumn(Bytes.toBytes("cf1"), Bytes.toBytes("q2"), Bytes.toBytes("valueB"));
    ```

```
put.addColumn(Bytes.toBytes("cf2"), Bytes.toBytes("q2"), Bytes.toBytes("valueC"));
table.put(put);
```

Incorrect write operations:

```
Put put1 = new Put(Bytes.toBytes("row"));
put1.addColumn(Bytes.toBytes("cf1"), Bytes.toBytes("q1"), Bytes.toBytes("valueA"));
table.put(put1);
Put put2 = new Put(Bytes.toBytes("row"));
put2.addColumn(Bytes.toBytes("cf1"), Bytes.toBytes("q2"), Bytes.toBytes("valueB"));
table.put(put2);
Put put3 = new Put(Bytes.toBytes("row"));
put3.addColumn(Bytes.toBytes("cf2"), Bytes.toBytes("q2"), Bytes.toBytes("valueC"));
table.put(put3);
```

- The combined conditions-based query is supported only when the combined index column contains filter criteria, or StartRow and StopRow are not specified for some index columns.

  Index: **IDX1=>cf1:[q1->datatype],[q2];cf2:[q1->datatype]**

  Correct query operations:

```
scan 'table', {FILTER=>"SingleColumnValueFilter('cf1','q1',>=,'binary:valueA',true,true) AND
SingleColumnValueFilter('cf1','q2',>=,'binary:valueB',true,true) AND
SingleColumnValueFilter('cf2','q1',>=,'binary:valueC',true,true) "}

scan 'table', {FILTER=>"SingleColumnValueFilter('cf1','q1',=,'binary:valueA',true,true) AND
SingleColumnValueFilter('cf1','q2',>=,'binary:valueB',true,true)" }

scan 'table', {FILTER=>"SingleColumnValueFilter('cf1','q1',>=,'binary:valueA',true,true) AND
SingleColumnValueFilter('cf1','q2',>=,'binary:valueB',true,true) AND
SingleColumnValueFilter('cf2','q1',>=,'binary:valueC',true,true)",STARTROW=>'row001',STOPROW
=>'row100'}
```

  Incorrect query operations:

```
scan 'table', {FILTER=>"SingleColumnValueFilter('cf1','q1',>=,'binary:valueA',true,true) AND
SingleColumnValueFilter('cf1','q2',>=,'binary:valueB',true,true) AND
SingleColumnValueFilter('cf2','q1',>=,'binary:valueC',true,true)  AND
SingleColumnValueFilter('cf2','q2',>=,'binary:valueD',true,true)"}

scan 'table', {FILTER=>"SingleColumnValueFilter('cf1','q1',=,'binary:valueA',true,true) AND
SingleColumnValueFilter('cf2','q1',>=,'binary:valueC',true,true)" }

scan 'table', {FILTER=>"SingleColumnValueFilter('cf1','q1',=,'binary:valueA',true,true) AND
SingleColumnValueFilter('cf2','q2',>=,'binary:valueD',true,true)" }

scan 'table', {FILTER=>"SingleColumnValueFilter('cf1','q1',=,'binary:valueA',true,true) AND
SingleColumnValueFilter('cf1','q2',>=,'binary:valueB',true,true)" ,STARTROW=>'row001',STOPROW
=>'row100' }
```

- Do not explicitly configure any split policy for tables with index data.
- Other mutation operations, such as **increment** and **append**, are not supported.
- Index of the column with **maxVersions** greater than 1 is not supported.
- The data index column in a row cannot be updated.

  Index 1: **IDX1=>cf1:[q1->datatype],[q2];cf2:[q1->datatype]**

  Index 2: **IDX2=>cf2:[q2->datatype]**

  Correct update operations:

```
Put put1 = new Put(Bytes.toBytes("row"));
put1.addColumn(Bytes.toBytes("cf1"), Bytes.toBytes("q1"), Bytes.toBytes("valueA"));
put1.addColumn(Bytes.toBytes("cf1"), Bytes.toBytes("q2"), Bytes.toBytes("valueB"));
put1.addColumn(Bytes.toBytes("cf2"), Bytes.toBytes("q1"), Bytes.toBytes("valueC"));
put1.addColumn(Bytes.toBytes("cf2"), Bytes.toBytes("q2"), Bytes.toBytes("valueD"));
table.put(put1);

Put put2 = new Put(Bytes.toBytes("row"));
```

```
put2.addColumn(Bytes.toBytes("cf1"), Bytes.toBytes("q3"), Bytes.toBytes("valueE"));
put2.addColumn(Bytes.toBytes("cf2"), Bytes.toBytes("q3"), Bytes.toBytes("valueF"));
table.put(put2);
```

Incorrect update operations:

```
Put put1 = new Put(Bytes.toBytes("row"));
put1.addColumn(Bytes.toBytes("cf1"), Bytes.toBytes("q1"), Bytes.toBytes("valueA"));
put1.addColumn(Bytes.toBytes("cf1"), Bytes.toBytes("q2"), Bytes.toBytes("valueB"));
put1.addColumn(Bytes.toBytes("cf2"), Bytes.toBytes("q1"), Bytes.toBytes("valueC"));
put1.addColumn(Bytes.toBytes("cf2"), Bytes.toBytes("q2"), Bytes.toBytes("valueD"));
table.put(put1);

Put put2 = new Put(Bytes.toBytes("row"));
put2.addColumn(Bytes.toBytes("cf1"), Bytes.toBytes("q1"), Bytes.toBytes("valueA_new"));
put2.addColumn(Bytes.toBytes("cf1"), Bytes.toBytes("q2"), Bytes.toBytes("valueB_new"));
put2.addColumn(Bytes.toBytes("cf2"), Bytes.toBytes("q1"), Bytes.toBytes("valueC_new"));
put2.addColumn(Bytes.toBytes("cf2"), Bytes.toBytes("q2"), Bytes.toBytes("valueD_new"));
table.put(put2);
```

- The table to which an index is added cannot contain a value greater than 32 KB.
- If user data is deleted due to the expiration of the column-level TTL, the corresponding index data is not deleted immediately. It will be deleted in the major compaction operation.
- The TTL of the user column family cannot be modified after the index is created.
  - If the TTL of a column family increases after an index is created, delete the index and re-create one. Otherwise, some generated index data will be deleted before user data is deleted.
  - If the TTL value of the column family decreases after an index is created, the index data will be deleted after user data is deleted.
- The index query does not support the reverse operation, and the query results are disordered.
- The index does not support the **clone snapshot** operation.
- The index table must use HIndexWALPlayer to replay logs. WALPlayer cannot be used to replay logs.

```
hbase org.apache.hadoop.hbase.hindex.mapreduce.HIndexWALPlayer
Usage: WALPlayer [options] <wal inputdir> <tables> [<tableMappings>]
Read all WAL entries for <tables>.
If no tables ("") are specific, all tables are imported.
(Careful, even -ROOT- and hbase:meta entries will be imported in that case.)
Otherwise <tables> is a comma separated list of tables.

The WAL entries can be mapped to new set of tables via <tableMapping>.
<tableMapping> is a command separated list of targettables.
If specified, each table in <tables> must have a mapping.

By default WALPlayer will load data directly into HBase.
To generate HFiles for a bulk data load instead, pass the option:
  -Dwal.bulk.output=/path/for/output
  (Only one table can be specified, and no mapping is allowed!)
Other options: (specify time range to WAL edit to consider)
  -Dwal.start.time=[date|ms]
  -Dwal.end.time=[date|ms]
For performance also consider the following options:
  -Dmapreduce.map.speculative=false
  -Dmapreduce.reduce.speculative=false
```

- When the **deleteall** command is executed for the index table, the performance is low.
- The index table does not support HBCK. To use HBCK to repair the index table, delete the index data first.

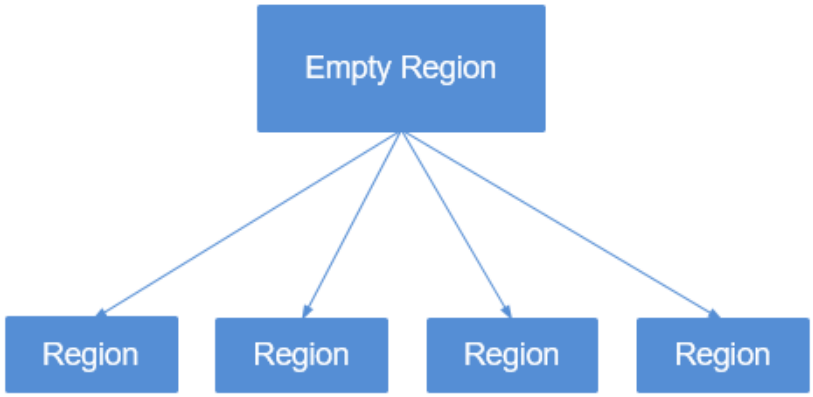
Multi-point Division

When you create tables that are pre-divided by region in HBase, you may not know the data distribution trend so the division by region may be inappropriate. After the system runs for a period, regions need to be divided again to achieve better performance. Only empty regions can be divided.

The region division function delivered with HBase divides regions only when they reach the threshold. This is called "single point division".

To achieve better performance when regions are divided based on user requirements, multi-point division is developed, which is also called "dynamic division". That is, an empty region is pre-divided into multiple regions to prevent performance deterioration caused by insufficient region space.

Figure 1-42 Multi-point division



Connection Limitation

Too many sessions mean that too many queries and MapReduce tasks are running on HBase, which compromises HBase performance and even causes service rejection. You can configure parameters to limit the maximum number of sessions that can be established between the client and the HBase server to achieve HBase overload protection.

Improved Disaster Recovery

The disaster recovery (DR) capabilities between the active and standby clusters can enhance HA of the HBase data. The active cluster provides data services and the standby cluster backs up data. If the active cluster is faulty, the standby cluster takes over data services. Compared with the open source replication function, this function is enhanced as follows:

1. The standby cluster whitelist function is only applicable to pushing data to a specified cluster IP address.
2. In the open source version, replication is synchronized based on WAL, and data backup is implemented by replaying WAL in the standby cluster. For BulkLoad operations, since no WAL is generated, data will not be replicated to the standby cluster. By recording BulkLoad operations on the WAL and

synchronizing them to the standby cluster, the standby cluster can read BulkLoad operation records through WAL and load HFile in the active cluster to the standby cluster to implement data backup.

3. In the open source version, HBase filters ACLs. Therefore, ACL information will not be synchronized to the standby cluster. By adding a filter (**org.apache.hadoop.hbase.replication.SystemTableWALEntryFilterAllowACL**), ACL information can be synchronized to the standby cluster. You can configure **hbase.replication.filter.sytemWALEntryFilter** to enable the filter and implement ACL synchronization.
4. As for read-only restriction of the standby cluster, only super users within the standby cluster can modify the HBase of the standby cluster. In other words, HBase clients outside the standby cluster can only read the HBase of the standby cluster.

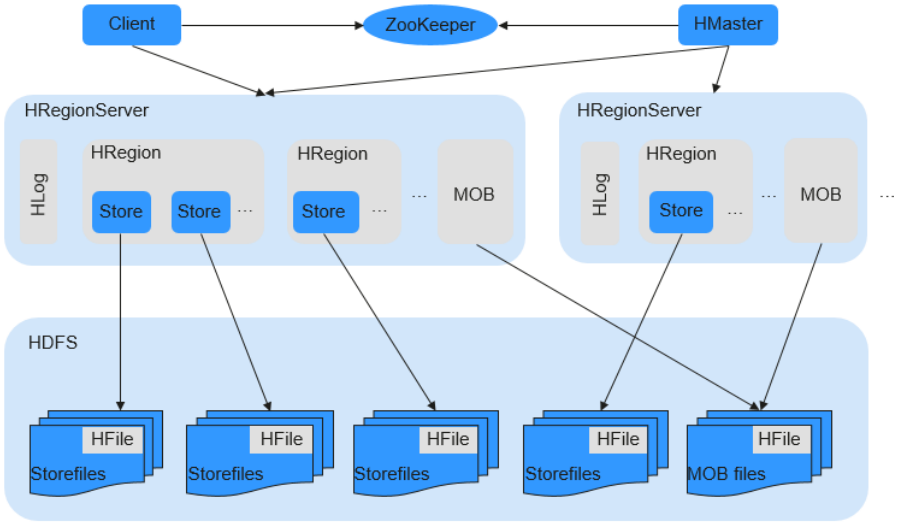
HBase MOB

In the actual application scenarios, data in various sizes needs to be stored, for example, image data and documents. Data whose size is smaller than 10 MB can be stored in HBase. HBase can yield the best read-and-write performance for data whose size is smaller than 100 KB. If the size of data stored in HBase is greater than 100 KB or even reaches 10 MB and the same number of data files are inserted, the total data amount is large, causing frequent compaction and split, high CPU consumption, high disk I/O frequency, and low performance.

MOB data (whose size ranges from 100 KB to 10 MB) is stored in a file system (for example, HDFS) in HFile format. The expiredMobFileCleaner and Sweeper tools are used to manage HFiles and save the address and size information about the HFiles to the store of HBase as values. This greatly decreases the compaction and split frequency in HBase and improves performance.

As shown in **Figure 1-43**, MOB indicates mobstore stored on HRegion. Mobstore stores keys and values. Wherein, a key is the corresponding key in HBase, and a value is the reference address and data offset stored in the file system. When reading data, mobstore uses its own scanner to read key-value data objects and uses the address and data size information in the value to obtain target data from the file system.

Figure 1-43 MOB data storage principle



HFS

HBase FileStream (HFS) is an independent HBase file storage module. It is used in MRS upper-layer applications by encapsulating HBase and HDFS interfaces to provide these upper-layer applications with functions such as file storage, read, and deletion.

In the Hadoop ecosystem, the HDFS and HBase face tough problems in mass file storage in some scenarios:

- If a large number of small files are stored in HDFS, the NameNode will be under great pressure.
- Some large files cannot be directly stored on HBase due to HBase APIs and internal mechanisms.

HFS is developed for the mixed storage of massive small files and some large files in Hadoop. Simply speaking, massive small files (smaller than 10 MB) and some large files (greater than 10 MB) need to be stored in HBase tables.

For such a scenario, HFS provides unified operation APIs similar to HBase function APIs.

Multiple RegionServers Deployed on the Same Server

Multiple RegionServers can be deployed on one node to improve HBase resource utilization.

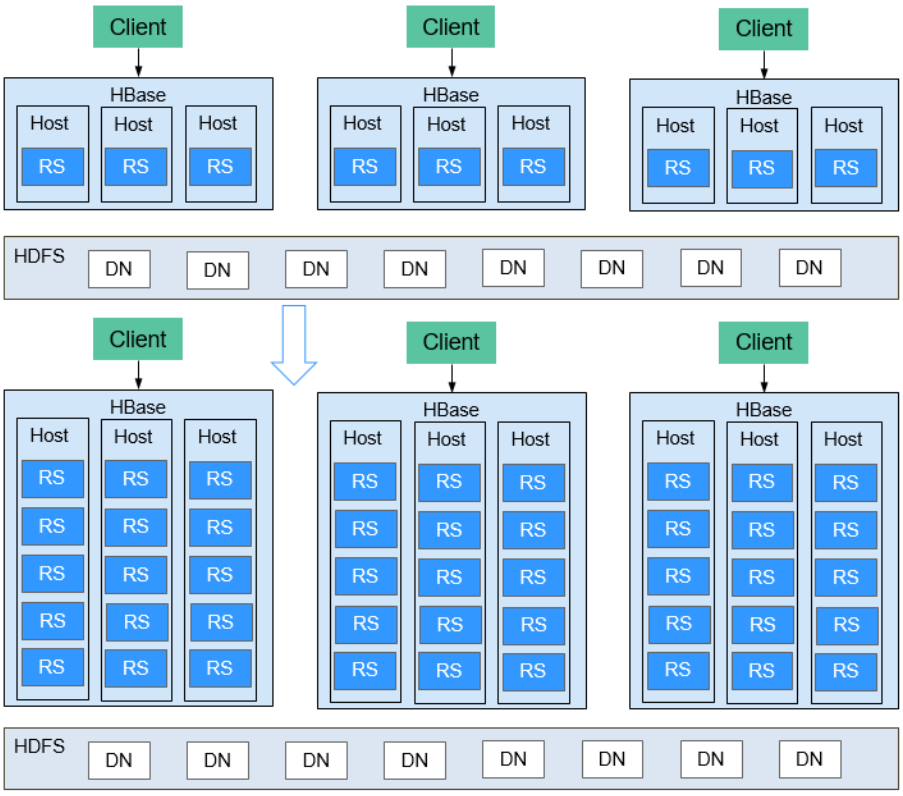
If only one RegionServer is deployed, resource utilization is low due to the following reasons:

1. A RegionServer supports a limited number of regions, and therefore memory and CPU resources cannot be fully used.
2. A single RegionServer supports a maximum of 20 TB data, of which two copies require 40 TB, and three copies require 60 TB. In this case, 96 TB capacity cannot be used up.
3. Poor write performance: One RegionServer is deployed on a physical server, and only one HLog exists. Only three disks can be written at the same time.

The HBase resource utilization can be improved when multiple RegionServers are deployed on the same server.

1. A physical server can be configured with a maximum of five RegionServers. The number of RegionServers deployed on each physical server can be configured as required.
2. Resources such as memory, disks, and CPUs can be fully used.
3. A physical server supports a maximum of five HLogs and allows data to be written to 15 disks at the same time, significantly improving write performance.

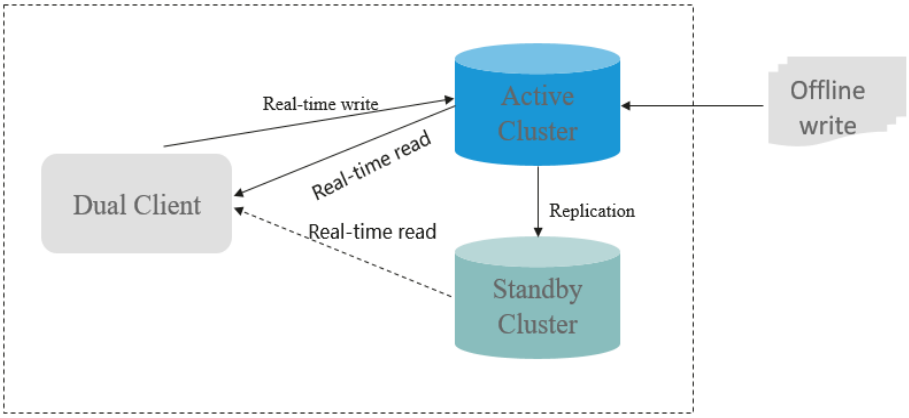
Figure 1-44 Improved HBase resource utilization



HBase Dual-Read

In the HBase storage scenario, it is difficult to ensure 99.9% query stability due to GC, network jitter, and bad sectors of disks. The HBase dual-read feature is added to meet the requirements of low glitches during large-data-volume random read.

The HBase dual-read feature is based on the DR capability of the active and standby clusters. The probability that the two clusters generate glitches at the same time is far less than that of one cluster. The dual-cluster concurrent access mode is used to ensure query stability. When a user initiates a query request, the HBase service of the two clusters is queried at the same time. If the active cluster does not return any result after a period of time (the maximum tolerable glitch time), the data of the cluster with the fastest response can be used. The following figure shows the working principle.



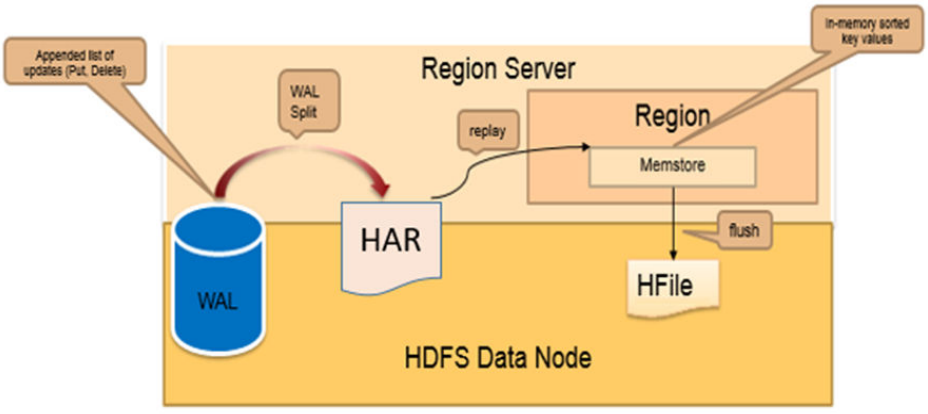
Custom Delimiters Supported on Phoenix CsvBulkLoadTool

Currently, Phoenix's open source CsvBulkLoadTool supports only a single character as the data delimiter. When a user data file contains any characters, a special string is used as the delimiter. To meet this requirement, custom delimiters are supported so you can use any visible characters within the specified length as delimiters to import data files.

Writting Small Files Generated During WAL File Spliting to the HTTP Archive (HAR) File

When a RegionServer is faulty or restarted, HMaster uses ServerCrashProcedure to restore the services running on the RegionServer. The restoration process involves splitting WAL files. During WAL file splitting, a large number of small files are generated, which may cause HDFS performance bottlenecks. As a result, service restoration takes a long time.

This feature writes small files to the HAR file during WAL file splitting to shorten the RegionServer restoration duration.



Batch TRSP

HBase 2.*x* uses HBase Procedure to rewrite the region assignment logic (AMV2). When each region is opened or closed, a TransitRegionStateProcedure (TRSP) is associated with it. When services running on a RegionServer need to be restored

due to RegionServer faults or restarts, HMaster creates a TRSP for each region to be restored. A large number of TRSPs need to persist data to Proc WAL files and perform an RPC interaction with RegionServer, which may cause HMaster performance bottlenecks. As a result, the service restoration takes a long time.

This feature attaches regions to TRSPs and uses one TRSP to restore all regions of a RegionServer. RegionServer batch opens or closes regions and reports all regions to HMaster at a time.

NOTE

This feature can only restore regions to their original RegionServers. Therefore, the prerequisite for this optimization to take effect is that the faulty or restarted RegionServer has been brought online again when HMaster creates a TRSP. This feature is used to optimize the duration for HBase restart or service fault restoration. If a few RegionServers are faulty, this feature may not take effect because HMaster had created TRSPs before RegionServers were brought online again.

HBase Self-Healing from Hotspotting

HBase is a distributed key-value database. Regions are the smallest units HBase data management. If table planning and rowkey design are improper, requests are distributed to a few fixed regions, and the service pressure is concentrated on a single node. As a result, the service performance deteriorates or even requests fail.

The MetricController instance is added to HBase. After the hotspotting detection capability is enabled, the request traffic of each RegionServer node can be monitored. Through aggregation analysis, the nodes and regions with excessive requests can be identified, helping quickly identify hotspotting. In addition, the self-healing from hotspotting function is provided to transfer workload or perform region splitting. If the self-healing from hotspotting function cannot be used (such as hotspotting on a single rowkey and sequential write hotspotting issues), the hotspot traffic limiting capability is provided instead to minimize the impact on other normal services on this node.

1.3.10 HDFS

1.3.10.1 HDFS Basic Principles

Hadoop Distributed File System (HDFS) implements reliable and distributed read/write of massive amounts of data. HDFS is applicable to the scenario where data read/write features "write once and read multiple times". However, the write operation is performed in sequence, that is, it is a write operation performed during file creation or an adding operation performed behind the existing file. HDFS ensures that only one caller can perform write operation on a file but multiple callers can perform read operation on the file at the same time.

Architecture

HDFS consists of active and standby NameNodes and multiple DataNodes, as shown in **Figure 1-45**.

HDFS works in master/slave architecture. NameNodes run on the master (active) node, and DataNodes run on the slave (standby) node. ZKFC should run along with the NameNodes.

The communication between NameNodes and DataNodes is based on Transmission Control Protocol (TCP)/Internet Protocol (IP). The NameNode, DataNode, ZKFC, and JournalNode can be deployed on Linux servers.

Figure 1-45 HA HDFS architecture

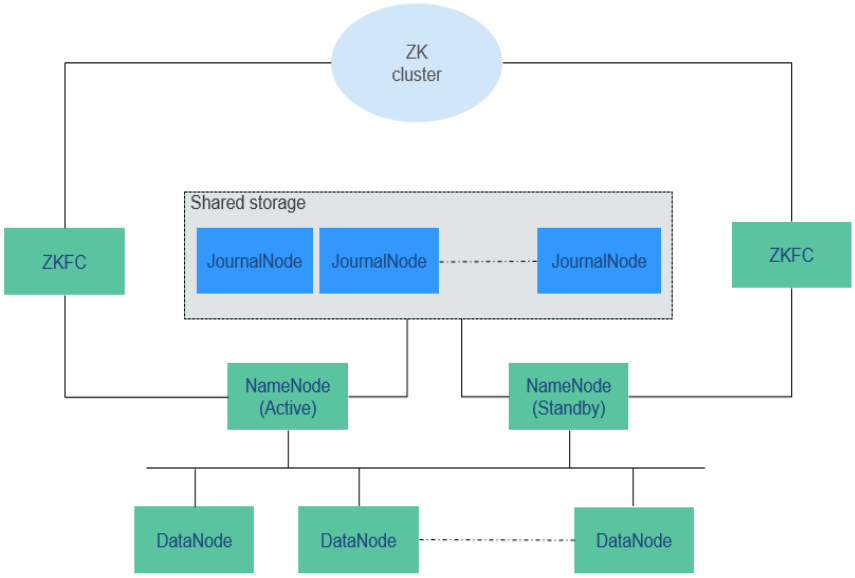


Table 1-9 describes the functions of each module shown in **Figure 1-45**.

Table 1-9 Module description

Module	Description
NameNode	A NameNode is used to manage the namespace, directory structure, and metadata information of a file system and provide the backup mechanism. The NameNode is classified into the following two types: • Active NameNode: manages the namespace, maintains the directory structure and metadata of file systems, and records the mapping relationships between data blocks and files to which the data blocks belong. • Standby NameNode: synchronizes with the data in the active NameNode, and takes over services from the active NameNode when the active NameNode is faulty. • Observer NameNode: synchronizes with the data in the active NameNode, and processes read requests from the client.
DataNode	A DataNode is used to store data blocks of each file and periodically report the storage status to the NameNode.
JournalNode	In HA cluster, synchronizes metadata between the active and standby NameNodes.

Module	Description
ZKFC	ZKFC must be deployed for each NameNode. It monitors NameNode status and writes status information to ZooKeeper. ZKFC also has permissions to select the active NameNode.
ZK Cluster	ZooKeeper is a coordination service which helps the ZKFC to elect the active NameNode.
HttpFS gateway	HttpFS is a single stateless gateway process which provides the WebHDFS REST API for external processes and FileSystem API for the HDFS. HttpFS is used for data transmission between different versions of Hadoop. It is also used as a gateway to access the HDFS behind a firewall.

- **HDFS HA Architecture**

  HA is used to resolve the SPOF problem of NameNode. This feature provides a standby NameNode for the active NameNode. When the active NameNode is faulty, the standby NameNode can quickly take over to continuously provide services for external systems.

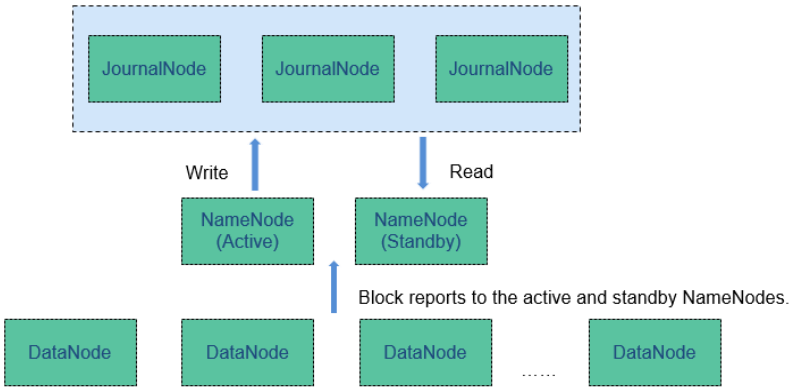
  In a typical HDFS HA scenario, there are usually two NameNodes. One is in the active state, and the other in the standby state.

  A shared storage system is required to support metadata synchronization of the active and standby NameNodes. This version provides Quorum Journal Manager (QJM) HA solution, as shown in **Figure 1-46**. A group of JournalNodes are used to synchronize metadata between the active and standby NameNodes.

  Generally, an odd number (2N+1) of JournalNodes are configured, and at least three JournalNodes are required. For one metadata update message, data writing is considered successful as long as data writing is successful on N +1 JournalNodes. In this case, data writing failure of a maximum of N JournalNodes is allowed. For example, when there are three JournalNodes, data writing failure of one JournalNode is allowed; when there are five JournalNodes, data writing failure of two JournalNodes is allowed.

  JournalNode is a lightweight daemon process and shares a host with other services of Hadoop. It is recommended that the JournalNode be deployed on the control node to prevent data writing failure on the JournalNode during massive data transmission.

Figure 1-46 QJM-based HDFS architecture

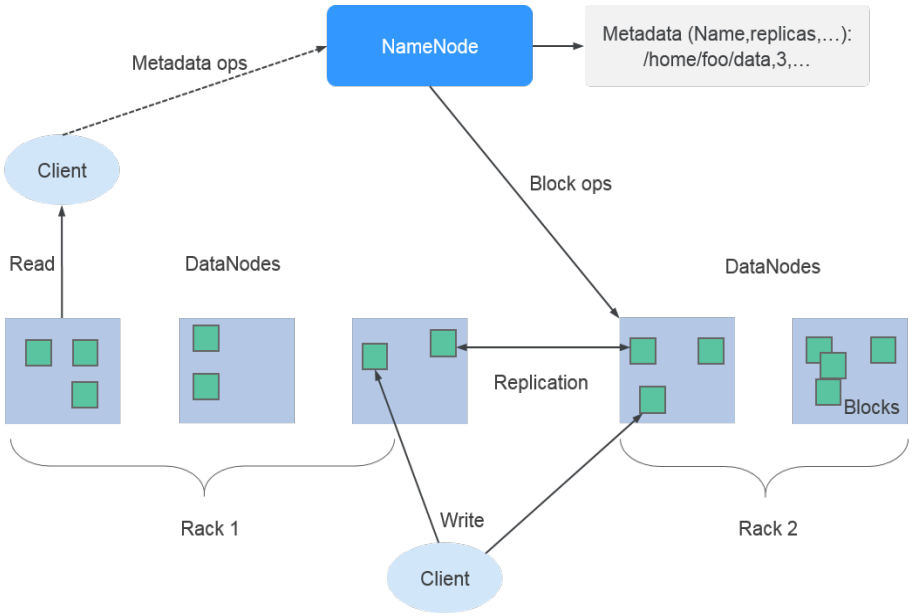


Principle

MRS uses the HDFS copy mechanism to ensure data reliability. One backup file is automatically generated for each file saved in HDFS, that is, two copies are generated in total. The number of HDFS copies can be queried using the **dfs.replication** parameter.

- When the Core node specification of the MRS cluster is set to non-local hard disk drive (HDD) and the cluster has only one Core node, the default number of HDFS copies is 1. If the number of Core nodes in the cluster is greater than or equal to 2, the default number of HDFS copies is 2.
- When the Core node specification of the MRS cluster is set to local disk and the cluster has only one Core node, the default number of HDFS copies is 1. If there are two Core nodes in the cluster, the default number of HDFS copies is 2. If the number of Core nodes in the cluster is greater than or equal to 3, the default number of HDFS copies is 3.

Figure 1-47 HDFS architecture



The HDFS component of MRS supports the following features:

- Supports erasure code, reducing data redundancy to 50% and improving reliability. In addition, the striped block storage structure is introduced to maximize the use of the capability of a single node and multiple disks in an existing cluster. After the coding process is introduced, the data write performance is improved, and the performance is close to that with the multi-copy redundancy.
- Supports balanced node scheduling on HDFS and balanced disk scheduling on a single node, improving HDFS storage performance after node or disk scale-out.

1.3.10.2 HDFS HA Solution

HDFS HA Background

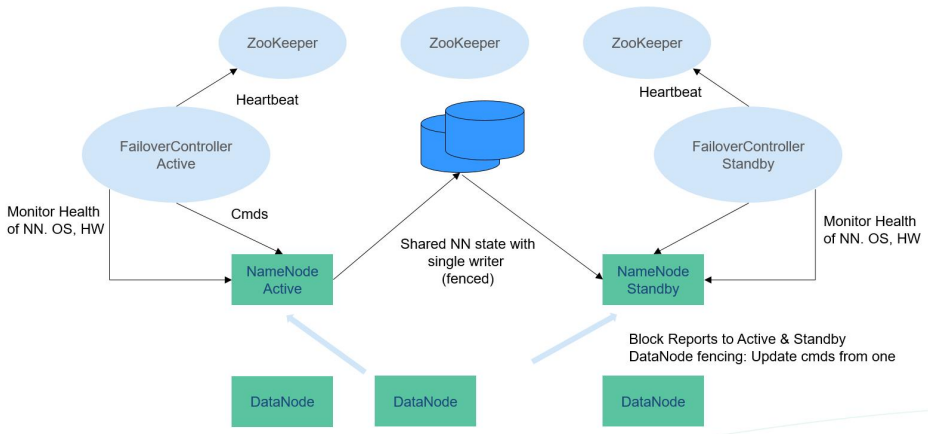
In versions earlier than Hadoop 2.0.0, SPOF occurs in the HDFS cluster. Each cluster has only one NameNode. If the host where the NameNode is located is faulty, the HDFS cluster cannot be used unless the NameNode is restarted or started on another host. This affects the overall availability of HDFS in the following aspects:

1. In the case of an unplanned event such as host breakdown, the cluster would be unavailable until the NameNode is restarted.
2. Planned maintenance tasks, such as software and hardware upgrade, will cause the cluster stop working.

To solve the preceding problems, the HDFS HA solution enables a hot-swap NameNode backup for NameNodes in a cluster in automatic or manual (configurable) mode. When a machine fails (due to hardware failure), the active/standby NameNode switches over automatically in a short time. When the active NameNode needs to be maintained, the MRS cluster administrator can manually perform an active/standby NameNode switchover to ensure cluster availability during maintenance.

HDFS HA Implementation

Figure 1-48 Typical HA deployment



In a typical HA cluster (as shown in **Figure 1-48**), two NameNodes need to be configured on two independent servers, respectively. At any time point, one NameNode is in the active state, and the other NameNode is in the standby state. The active NameNode is responsible for all client operations in the cluster, while the standby NameNode maintains synchronization with the active node to provide fast switchover if necessary.

To keep the data synchronized with each other, both nodes communicate with a group of JournalNodes. When the active node modifies any file system's metadata, it will store the modification log to a majority of these JournalNodes. For example, if there are three JournalNodes, then the log will be saved on two of them at least. The standby node monitors changes of JournalNodes and synchronizes changes from the active node. Based on the modification log, the standby node applies the changes to the metadata of the local file system. Once a switchover occurs, the standby node can ensure its status is the same as that of the active node. This ensures that the metadata of the file system is synchronized between the active and standby nodes if the switchover is incurred by the failure of the active node.

To ensure fast switchover, the standby node needs to have the latest block information. Therefore, DataNodes send block information and heartbeat messages to two NameNodes at the same time.

It is vital for an HA cluster that only one of the NameNodes be active at any time. Otherwise, the namespace state would split into two parts, risking data loss or other incorrect results. To prevent the so-called "split-brain scenario", the JournalNodes will only ever allow a single NameNode to write data to it at a time. During switchover, the NameNode which is to become active will take over the role of writing data to JournalNodes. This effectively prevents the other NameNodes from being in the active state, allowing the new active node to safely proceed with switchover.

1.3.10.3 Relationship Between HDFS and Other Components

Relationship Between HDFS and HBase

HDFS is a subproject of Apache Hadoop, which is used as the file storage system for HBase. HBase is located in the structured storage layer. HDFS provides highly reliable support for lower-layer storage of HBase. All the data files of HBase can be stored in the HDFS, except some log files generated by HBase.

Relationship Between HDFS and MapReduce

- HDFS features high fault tolerance and high throughput, and can be deployed on low-cost hardware for storing data of applications with massive data sets.
- MapReduce is a programming model used for parallel computation of large data sets (larger than 1 TB). Data computed by MapReduce comes from multiple data sources, such as Local FileSystem, HDFS, and databases. Most data comes from the HDFS. The high throughput of HDFS can be used to read massive data. After being computed, data can be stored in HDFS.

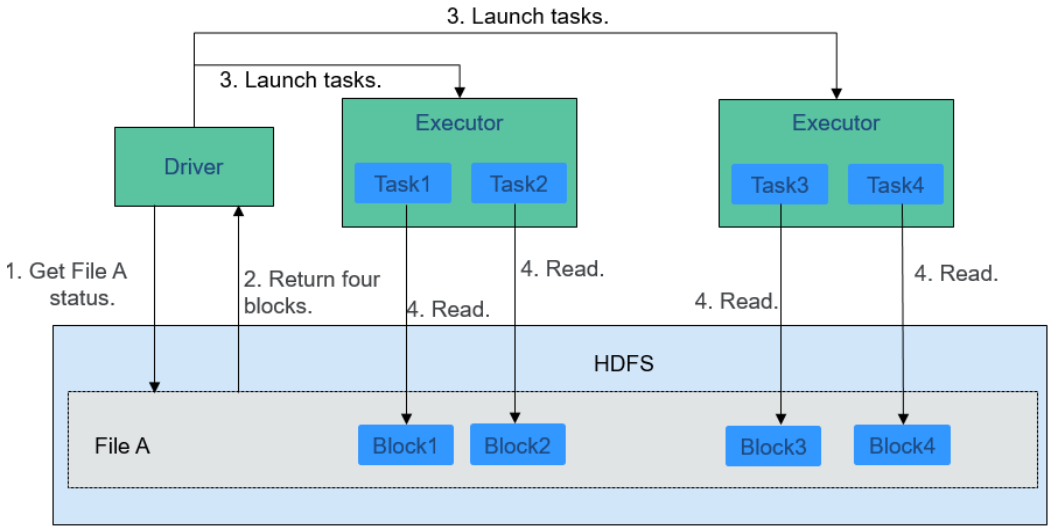
Relationship Between HDFS and Spark

Data computed by Spark comes from multiple data sources, such as local files and HDFS. Most data comes from HDFS which can read data in large scale for parallel computing. After being computed, data can be stored in HDFS.

Spark involves Driver and Executor. Driver schedules tasks and Executor runs tasks.

Figure 1-49 shows how data is read from a file.

Figure 1-49 File reading process

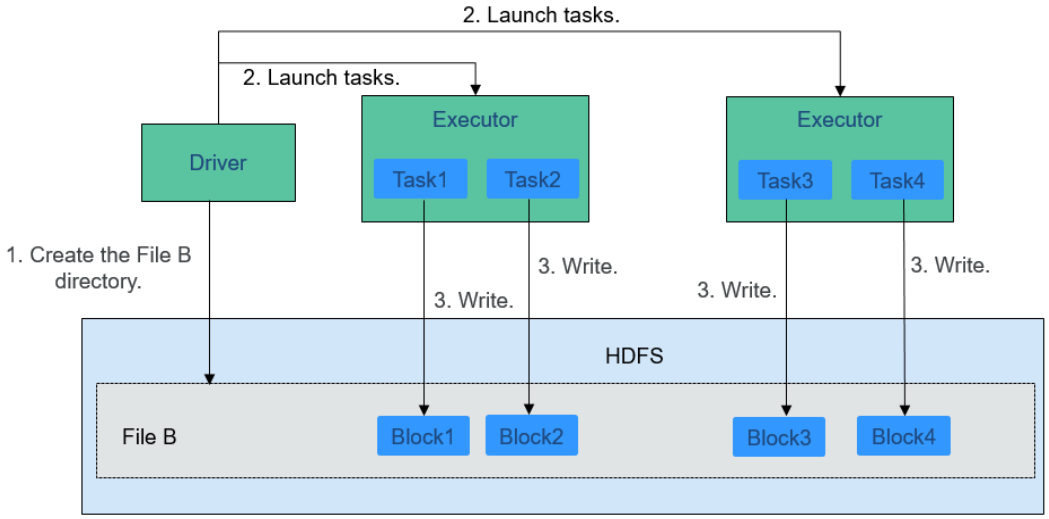


The file reading process is as follows:

1. Driver interconnects with HDFS to obtain the information of File A.
2. The HDFS returns the detailed block information about this file.
3. Driver sets a parallel degree based on the block data amount, and creates multiple tasks to read the blocks of this file.
4. Executor runs the tasks and reads the detailed blocks as part of the Resilient Distributed Dataset (RDD).

Figure 1-50 shows how data is written to a file.

Figure 1-50 File writing process



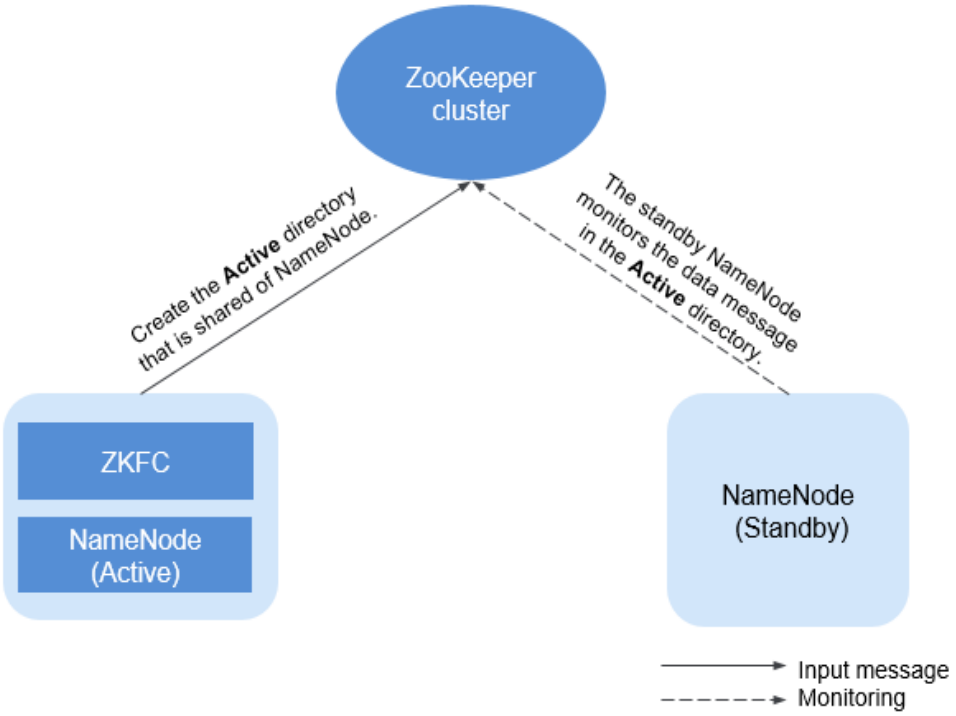
The file writing process is as follows:

1. Driver creates a directory where the file is to be written.
2. Based on the RDD distribution status, the number of tasks related to data writing is computed, and these tasks are sent to Executor.
3. Executor runs these tasks, and writes the computed RDD data to the directory created in 1.

Relationship Between HDFS and ZooKeeper

Figure 1-51 shows the relationship between ZooKeeper and HDFS.

Figure 1-51 Relationship between ZooKeeper and HDFS



As the client of a ZooKeeper cluster, ZKFailoverController (ZKFC) monitors the status of NameNode. ZKFC is deployed only in the node where NameNode resides, and in both the active and standby HDFS NameNodes.

1. The ZKFC connects to ZooKeeper and saves information such as host names to ZooKeeper under the znode directory **/hadoop-ha**. NameNode that creates the directory first is considered as the active node, and the other is the standby node. NameNodes read the NameNode information periodically through ZooKeeper.
2. When the process of the active node ends abnormally, the standby NameNode detects changes in the **/hadoop-ha** directory through ZooKeeper, and then takes over the service of the active NameNode.

1.3.10.4 HDFS Enhanced Open Source Features

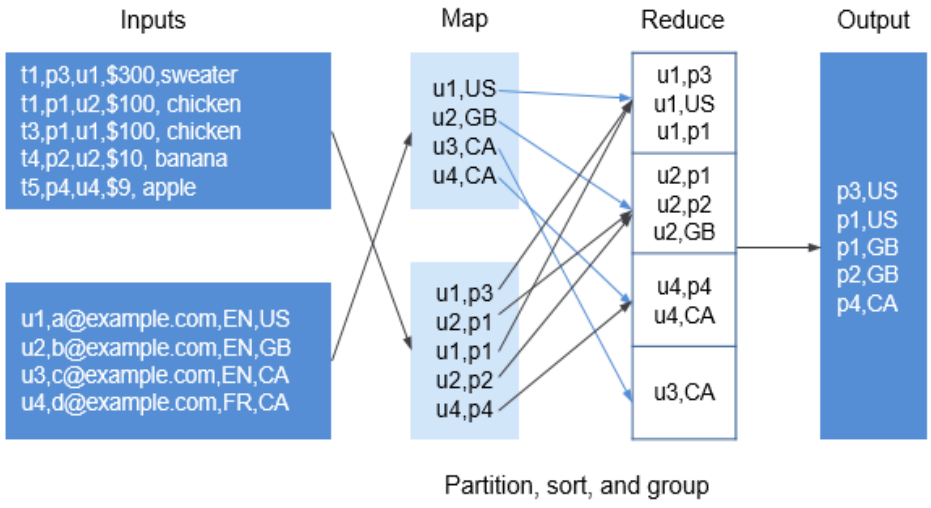
Enhanced Open Source Feature: File Block Colocation

In the offline data summary and statistics scenario, Join is a frequently used computing function, and is implemented in MapReduce as follows:

1. The Map task processes the records in the two table files into Join Key and Value, performs hash partitioning by Join Key, and sends the data to different Reduce tasks for processing.
2. Reduce tasks read data in the left table recursively in the nested loop mode and traverse each line of the right table. If join key values are identical, join results are output.

   The preceding method sharply reduces the performance of the join calculation. Because a large amount of network data transfer is required when the data stored in different nodes is sent from MAP to Reduce, as shown in **Figure 1-52**.

Figure 1-52 Data transmission in the non-colocation scenario

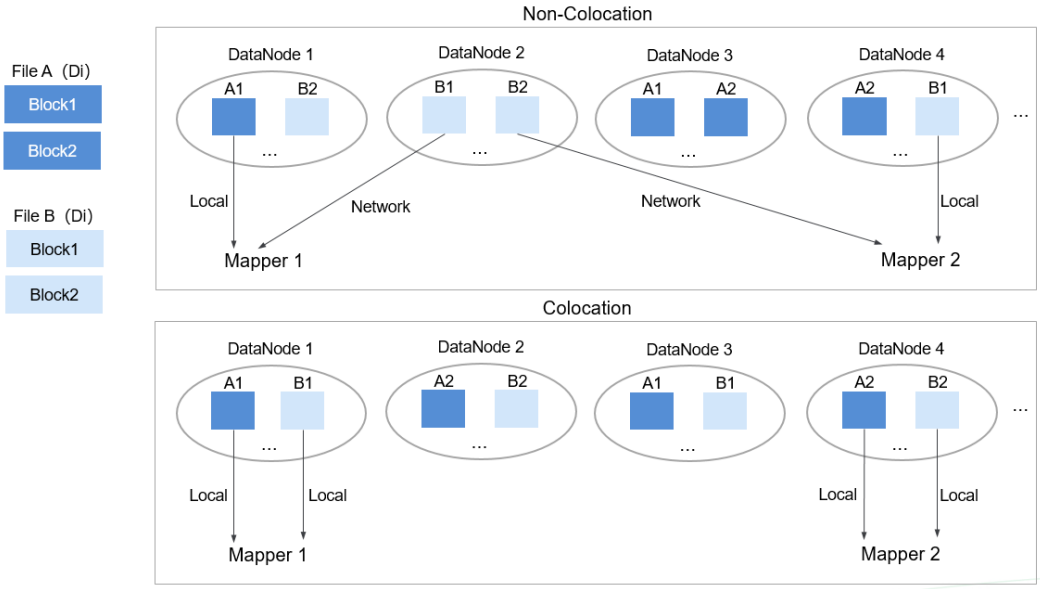


Data tables are stored in physical file system by HDFS block. Therefore, if two to-be-joined blocks are put into the same host accordingly after they are partitioned

by join key, you can obtain the results directly from Map join in the local node without any data transfer in the Reduce process of the join calculation. This will greatly improve the performance.

With the identical distribution feature of HDFS data, a same distribution ID is allocated to files, FileA and FileB, on which association and summation calculations need to be performed. In this way, all the blocks are distributed together, and calculation can be performed without retrieving data across nodes, which greatly improves the MapReduce join performance.

Figure 1-53 Data block distribution in colocation and non-colocation scenarios

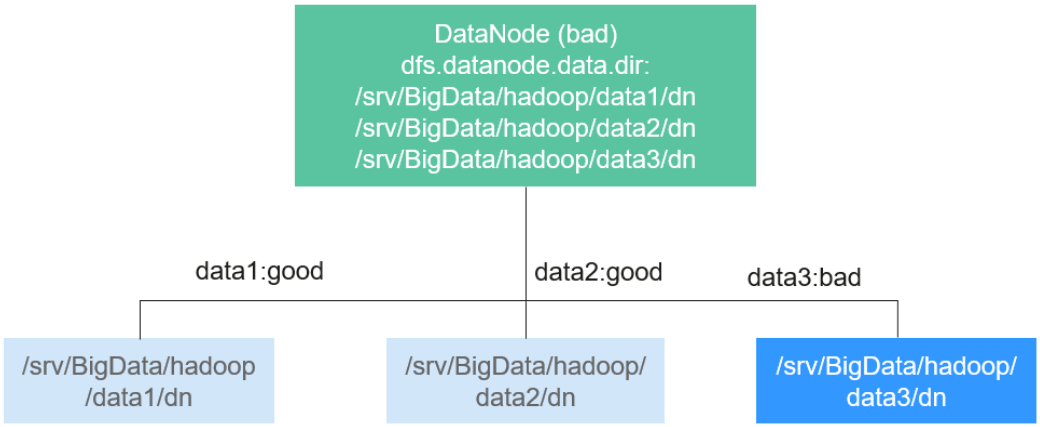


Enhanced Open Source Feature: Damaged Hard Disk Volume Configuration

In the open source version, if multiple data storage volumes are configured for a DataNode, the DataNode stops providing services by default if one of the volumes is damaged. If the configuration item **dfs.datanode.failed.volumes.tolerated** is set to specify the number of damaged volumes that are allowed, DataNode continues to provide services when the number of damaged volumes does not exceed the threshold.

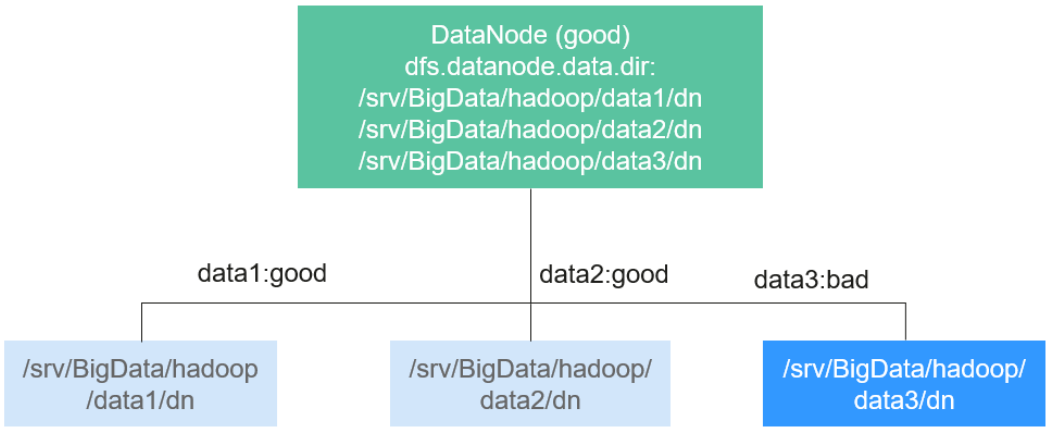
The value of **dfs.datanode.failed.volumes.tolerated** ranges from -1 to the number of disk volumes configured on the DataNode. The default value is **-1**, as shown in **Figure 1-54**.

Figure 1-54 Item being set to 0



For example, three data storage volumes are mounted to a DataNode, and **dfs.datanode.failed.volumes.tolerated** is set to 1. In this case, if one data storage volume of the DataNode is unavailable, this DataNode can still provide services, as shown in **Figure 1-55**.

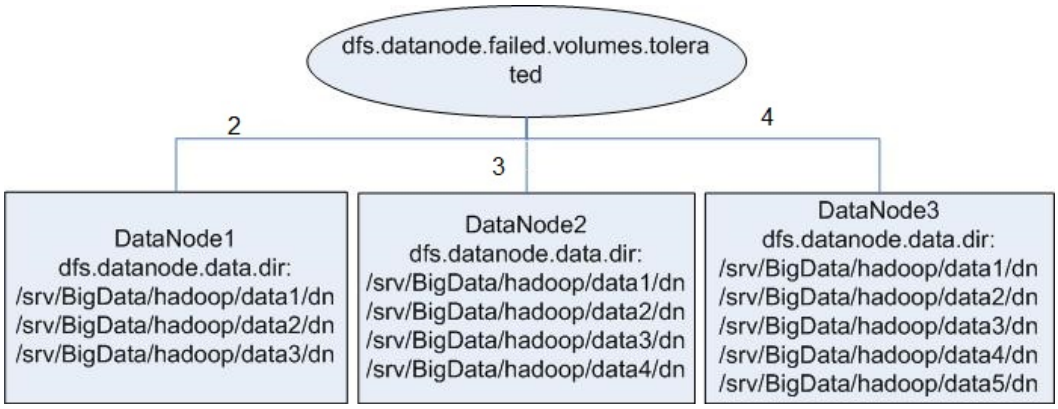
Figure 1-55 Item being set to 1



This native configuration item has some defects. When the number of data storage volumes in each DataNode is inconsistent, you need to configure each DataNode independently instead of generating the unified configuration file for all nodes.

Assume that there are three DataNodes in a cluster. The first node has three data directories, the second node has four, and the third node has five. If you want to ensure that DataNode services are available when only one data directory is available, you need to perform the configuration as shown in **Figure 1-56**.

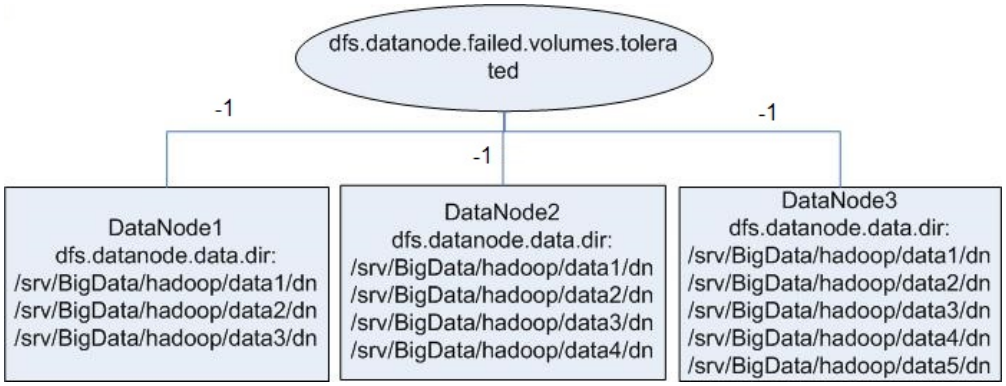
Figure 1-56 Attribute configuration before being enhanced



In self-developed enhanced HDFS, this configuration item is enhanced, with a value **-1** added. When this configuration item is set to **-1**, all DataNodes can provide services as long as one data storage volume in all DataNodes is available.

To resolve the problem in the preceding example, set this configuration to **-1**, as shown in **Figure 1-57**.

Figure 1-57 Attribute configuration after being enhanced



Enhanced Open Source Feature: HDFS Startup Acceleration

In HDFS, when NameNodes start, the metadata file FsImage needs to be loaded. Then, DataNodes will report the data block information after the DataNodes startup. When the data block information reported by DataNodes reaches the preset percentage, NameNodes exits safe mode to complete the startup process. If the number of files stored on the HDFS reaches the million or billion level, the two processes are time-consuming and will lead to a long startup time of the NameNode. Therefore, this version optimizes the process of loading metadata file FsImage.

In the open source HDFS, FsImage stores all types of metadata information. Each type of metadata information (such as file metadata information and folder metadata information) is stored in a section block, respectively. These section blocks are loaded in serial mode during startup. If a large number of files and folders are stored on the HDFS, loading of the two sections is time-consuming, prolonging the HDFS startup time. HDFS NameNode divides each type of metadata by segments and stores the data in multiple sections when generating

the FsImage files. When the NameNodes start, sections are loaded in parallel mode. This accelerates the HDFS startup.

Enhanced Open Source Feature: Label-based Block Placement Policies (HDFS Nodelabel)

You need to configure the nodes for storing HDFS file data blocks based on data features. You can configure a label expression to an HDFS directory or file and assign one or more labels to a DataNode so that file data blocks can be stored on specified DataNodes. If the label-based data block placement policy is used for selecting DataNodes to store the specified files, the DataNode range is specified based on the label expression. Then proper nodes are selected from the specified range.

- You can store the replicas of data blocks to the nodes with different labels accordingly. For example, store two replicas of the data block to the node labeled with L1, and store other replicas of the data block to the nodes labeled with L2.
- You can set the policy in case of block placement failure, for example, select a node from all nodes randomly.

Figure 1-58 gives an example:

- Data in **/HBase** is stored in A, B, and D.
- Data in **/Spark** is stored in A, B, D, E, and F.
- Data in **/user** is stored in C, D, and F.
- Data in **/user/shl** is stored in A, E, and F.

Figure 1-58 Example of label-based block placement policy

Enhanced Open Source Feature: HDFS Load Balance

The current read and write policies of HDFS are mainly for local optimization without considering the actual load of nodes or disks. Based on I/O loads of different nodes, the load balance of HDFS ensures that when read and write operations are performed on the HDFS client, the node with low I/O load is selected to perform such operations to balance I/O load and fully utilize the overall throughput of the cluster.

If HDFS Load Balance is enabled during file writing, the NameNode selects a DataNode (in the order of local node, local rack, and remote rack). If the I/O load of the selected node is heavy, the NameNode will choose another DataNode with lighter load.

If HDFS Load Balance is enabled during file reading, an HDFS client sends a request to the NameNode to provide the list of DataNodes that store the block to be read. The NameNode returns a list of DataNodes sorted by distance in the network topology. With the HDFS Load Balance feature, the DataNodes on the list are also sorted by their I/O load. The DataNodes with heavy load are at the bottom of the list.

Enhanced Open Source Feature: HDFS Auto Data Movement

Hadoop has been used for batch processing of immense data in a long time. The existing HDFS model is used to fit the needs of batch processing applications very well because such applications focus more on throughput than delay.

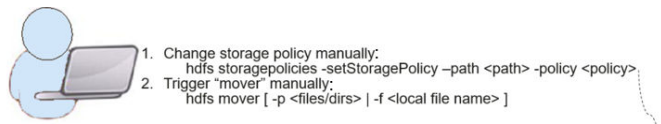
However, as Hadoop is increasingly used for upper-layer applications that demand frequent random I/O access such as Hive and HBase, low latency disks such as solid state disk (SSD) are favored in delay-sensitive scenarios. To cater to the trend, HDFS supports a variety of storage types. Users can choose a storage type according to their needs.

Storage policies vary depending on how frequently data is used. For example, if data that is frequently accessed in the HDFS is marked as **ALL_SSD** or **HOT**, the data that is accessed several times may be marked as **WARM**, and data that is rarely accessed (only once or twice access) can be marked as **COLD**. You can select different data storage policies based on the data access frequency.

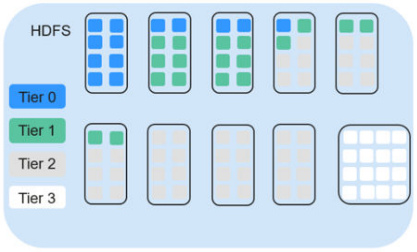
However, low latency disks are far more expensive than spinning disks. Data typically sees heavy initial usage with decline in usage over a period of time. Therefore, it can be useful if data that is no longer used is moved out from expensive disks to cheaper ones storage media.

A typical example is storage of detail records. New detail records are imported into SSD because they are frequently queried by upper-layer applications. As access frequency to these detail records declines, they are moved to cheaper storage.

Before automatic data movement is achieved, you have to manually determine by service type whether data is frequently used, manually set a data storage policy, and manually trigger the HDFS Auto Data Movement Tool, as shown in the figure below.



Policy ID	PolicyName	Block Placement (n replicas)	Fallback storages for creation	Fallback storages for replication
15	Lazy_Persist	RAN_DISK:1 DISK:n-1	DISK	DISK
12	All_SSD	SSD:n	DISK	DISK
10	One_SSD	SSD:1,DISK:n-1	SSD,DISK	SSD,DISK
7	Hot(default)	DISK:n	<none>	ARCHIVE
5	Warm	DISK:1,ARCHIVE:n-1	ARCHIVE, DISK	ARCHIVE, DISK
2	Cold	ARCHIVE:n	<none>	<none>



If aged data can be automatically identified and moved to cheaper storage (such as disk/archive), you will see significant cost cuts and data management efficiency improvement.

The HDFS Auto Data Movement Tool is at the core of HDFS Auto Data Movement. It automatically sets a storage policy depending on how frequently data is used. Specifically, functions of the HDFS Auto Data Movement Tool can:

- Mark a data storage policy as **All_SSD**, **One_SSD**, **Hot**, **Warm**, **Cold**, or **FROZEN** according to age, access time, and manual data movement rules.
- Define rules for distinguishing cold and hot data based on the data age, access time, and manual migration rules.
- Define the action to be taken if age-based rules are met.

  MARK: the action for identifying whether data is frequently or rarely used based on the age rules and setting a data storage policy. **MOVE**: the action for invoking the HDFS Auto Data Movement Tool and moving data based on the age rules to identify whether data is frequently or rarely used after you have determined the corresponding storage policy.

  - **MARK**: identifies whether data is frequently or rarely used and sets the data storage policy.
  - **MOVE**: the action for invoking the HDFS Auto Data Movement Tool and moving data across tiers.
  - **SET_REPL**: the action for setting new replica quantity for a file.
  - **MOVE_TO_FOLDER**: the action for moving files to a target folder.
  - **DELETE**: the action for deleting a file or directory.
  - **SET_NODE_LABEL**: the action for setting node labels of a file.

With the HDFS Auto Data Movement feature, you only need to define age based on access time rules. HDFS Auto Data Movement Tool matches data according to age-based rules, sets storage policies, and moves data. In this way, data management efficiency and cluster resource efficiency are improved.

1.3.11 HetuEngine

1.3.11.1 HetuEngine Product Overview

HetuEngine Description

HetuEngine is an in-house high-performance, interactive SQL analysis and data virtualization engine. It seamlessly integrates with the big data ecosystem to implement interactive query of massive amounts of data within seconds, and supports cross-source and cross-domain unified data access to enable one-stop SQL convergence analysis in the data lake, between lakes, and between lakehouses.

HetuEngine Architecture

HetuEngine consists of different modules. **Figure 1-59** shows the architecture.

Figure 1-59 HetuEngine architecture

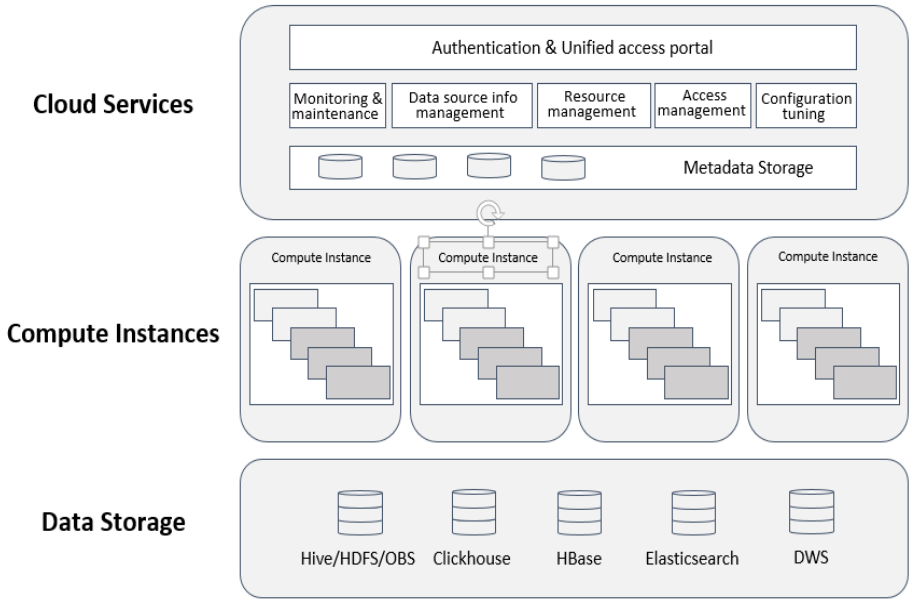


Table 1-10 Module description

Module	Concept	Description
Cloud service layer	HetuEngine CLI/ JDBC	HetuEngine client, through which the query request is submitted and the results is returned and displayed.
	HSBroker	Service management component of HetuEngine. It manages and verifies compute instances, monitors health status, and performs automatic maintenance.
	HSConsole	Provides visualized operation GUIs and RESTful APIs for data source information management, compute instance management, and automatic task query.
	HSFabric	Provides a unified SQL access entry to meet the requirements for high-performing and highly secure data transfer across domains (data centers).
Engine layer	Coordinator	Management node of HetuEngine compute instances. It receives and parses SQL statements, generates and optimizes execution plans, assigns tasks, and schedules resources.
	Worker	Work node of HetuEngine compute instances. It provides capabilities such as parallel data pulling from data sources and distributed SQL computing.

HetuEngine Application Scenarios

HetuEngine supports cross-source (multiple data sources, such as Hive, HBase, GaussDB(DWS), Elasticsearch, and ClickHouse) and cross-domain (multiple

regions or data centers) quick joint query, especially for interactive quick query of Hive and Hudi data in the Hadoop cluster (MRS).

1.3.11.2 Relationship Between HetuEngine and Other Components

The HetuEngine installation depends on the MRS cluster. **Table 1-11** lists the components on which the HetuServer installation depends.

Table 1-11 Components on which HetuEngine depends

Name	Description
HDFS	Hadoop Distributed File System, supporting high-throughput data access and suitable for applications with large-scale data sets.
Hive	Open-source data warehouse built on Hadoop. It stores structured data and implements basic data analysis using the Hive Query Language (HQL), a SQL-like language.
ZooKeeper	Enables highly reliable distributed coordination. It helps prevent single point of failures (SPOFs) and provides reliable services for applications.
KrbServer	Key management center that distributes bills.
Yarn	Resource management system, which is a general resource module that manages and schedules resources for various applications.
DBService	DBService is a high-availability relational database storage system that provides metadata backup and restoration functions.

1.3.12 Hive

1.3.12.1 Hive Basic Principles

Hive is a data warehouse built on Hadoop. It provides batch computing capability for the big data platform and is able to batch analyze and summarize structured and semi-structured data for data calculation. Hive operates structured data using Hive Query Language (HQL), a SQL-like language. HQL is automatically converted into MapReduce tasks for the query and analysis of massive data in the Hadoop cluster.

Hive provides the following functions:

- Analyzes massive structured data and summarizes analysis results.
- Allows complex MapReduce jobs to be compiled in SQL languages.

- Supports flexible data storage formats, including JavaScript object notation (JSON), comma separated values (CSV), TextFile, RCFile, SequenceFile, and ORC (Optimized Row Columnar).

Hive Framework

Hive is a single-instance service process that provides services by translating HQL into related MapReduce jobs or HDFS operations. **Figure 1-60** shows how Hive is connected to other components.

Figure 1-60 Hive framework

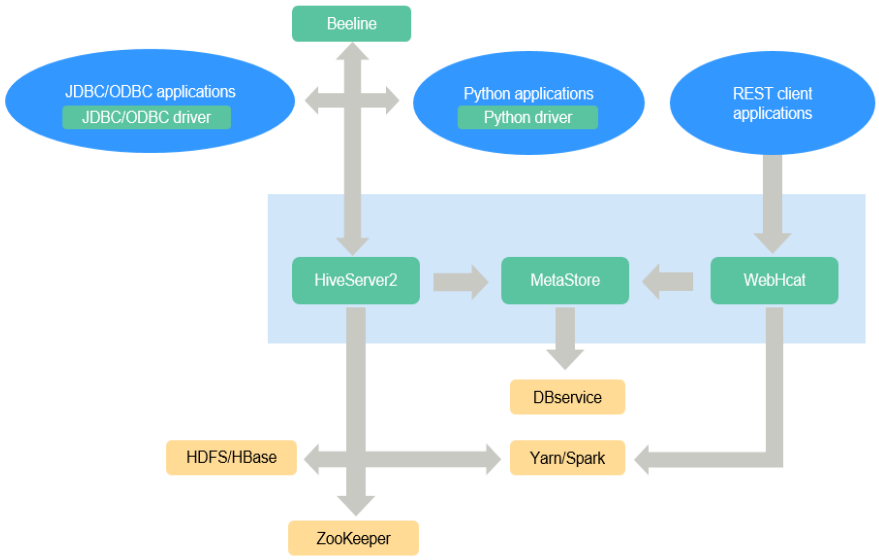

Table 1-12 Module description

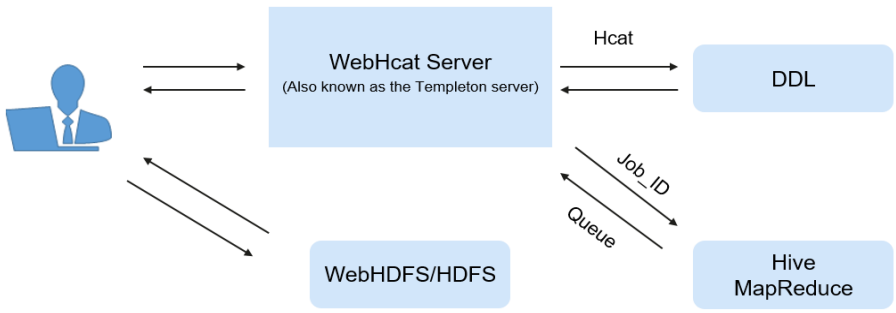
Module	Description
HiveServer	Multiple HiveServers can be deployed in a cluster to share loads. HiveServer provides Hive database services externally, translates HQL statements into related YARN tasks or HDFS operations to complete data extraction, conversion, and analysis.
MetaStore	• Multiple MetaStores can be deployed in a cluster to share loads. MetaStore provides Hive metadata services as well as reads, writes, maintains, and modifies the structure and properties of Hive tables. • MetaStore provides Thrift APIs for HiveServer, Spark, WebHCat, and other MetaStore clients to access and operate metadata.
WebHCat	Multiple WebHCats can be deployed in a cluster to share loads. WebHCat provides REST APIs and runs the Hive commands through the REST APIs to submit MapReduce jobs.

Module	Description
Hive client	Hive client includes the human-machine command-line interface (CLI) Beeline, JDBC drive for JDBC applications, Python driver for Python applications, and HCatalog JAR files for MapReduce.
ZooKeeper cluster	As a temporary node, ZooKeeper records the IP address list of each HiveServer instance. The client driver connects to ZooKeeper to obtain the list and selects corresponding HiveServer instances based on the routing mechanism.
HDFS/HBase cluster	The HDFS cluster stores the Hive table data.
MapReduce/ YARN cluster	Provides distributed computing services. Most Hive data operations rely on MapReduce. The main function of HiveServer is to translate HQL statements into MapReduce jobs to process massive data.

HCatalog is built on Hive Metastore and incorporates the DDL capability of Hive. HCatalog is also a Hadoop-based table and storage management layer that enables convenient data read/write on tables of HDFS by using different data processing tools such as MapReduce. Besides, HCatalog also provides read/write APIs for these tools and uses a Hive CLI to publish commands for defining data and querying metadata. After encapsulating these commands, WebHCat Server can provide RESTful APIs, as shown in **Figure 1-61**.

Figure 1-61 WebHCat logical architecture



Principles

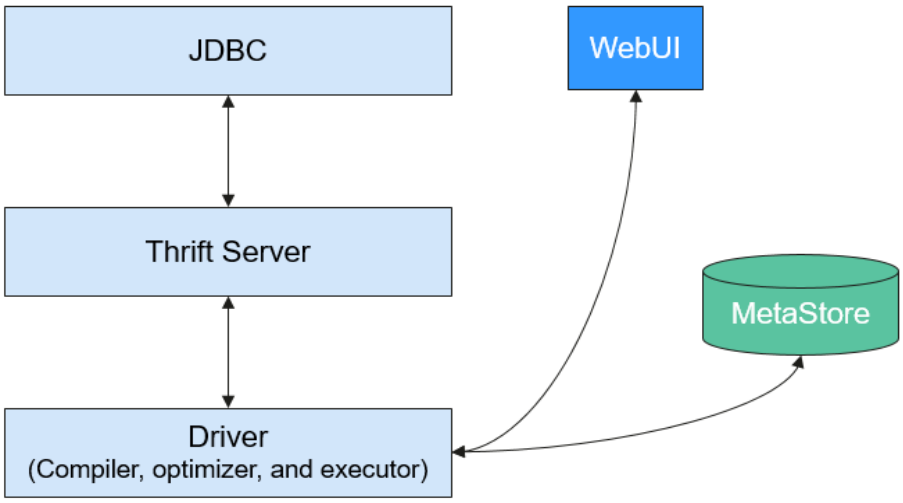
Hive functions as a data warehouse based on HDFS and MapReduce architecture and translates HQL statements into MapReduce jobs or HDFS operations.

Figure 1-62 shows the Hive structure.

- **Metastore**: reads, writes, and updates metadata such as tables, columns, and partitions. Its lower layer is relational databases.
- **Driver**: manages the lifecycle of HiveQL execution and participates in the entire Hive job execution.

- **Compiler**: translates HQL statements into a series of interdependent Map or Reduce jobs.
- **Optimizer**: is classified into logical optimizer and physical optimizer to optimize HQL execution plans and MapReduce jobs, respectively.
- **Executor**: runs Map or Reduce jobs based on job dependencies.
- **ThriftServer**: functions as the servers of JDBC, provides Thrift APIs, and integrates with Hive and other applications.
- **Clients**: include the WebUI and JDBC APIs and provides APIs for user access.

Figure 1-62 Hive framework



1.3.12.2 Hive CBO Principles

Hive CBO Principles

CBO is short for Cost-Based Optimization.

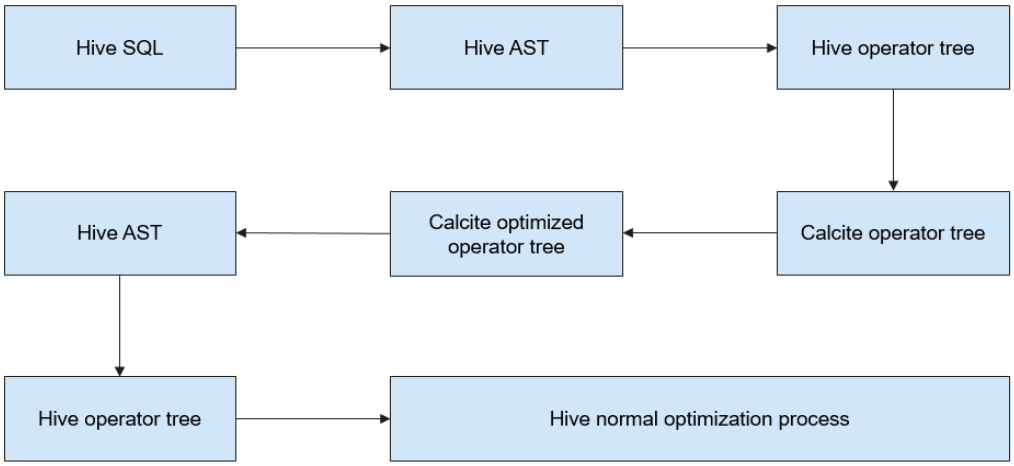
It will optimize the following:

During compilation, the CBO calculates the most efficient join sequence based on tables and query conditions involved in query statements to reduce time and resources required for query.

In Hive, the CBO is implemented as follows:

Hive uses open-source component Apache Calcite to implement the CBO. SQL statements are first converted into Hive Abstract Syntax Trees (ASTs) and then into RelNodes that can be identified by Calcite. After Calcite adjusts the join sequence in RelNodes, RelNodes are converted into ASTs by Hive to continue the logical and physical optimization. **Figure 1-63** shows the working flow.

Figure 1-63 CBO Implementation process



Calcite adjusts the join sequence as follows:

1. A table is selected as the first table from the tables to be joined.
2. The second and third tables are selected based on the cost. In this way, multiple different execution plans are obtained.
3. A plan with the minimum costs is calculated and serves as the final sequence.

The cost calculation method is as follows:

In the current version, costs are measured based on the number of data entries after joining. Fewer data entries mean less cost. The number of joined data entries depends on the selection rate of joined tables. The number of data entries in a table is obtained based on the table-level statistics.

The number of data entries in a table after filtering is estimated based on the column-level statistics, including the maximum values (max), minimum values (min), and Number of Distinct Values (NDV).

For example, there is a table **table_a** whose total number of data records is 1,000,000 and NDV is 50. The query conditions are as follows:

```
Select * from table_a where colum_a='value1';
```

The estimated number of queried data entries is: 1,000,000 x 1/50 = 20,000. The selection rate is 2%.

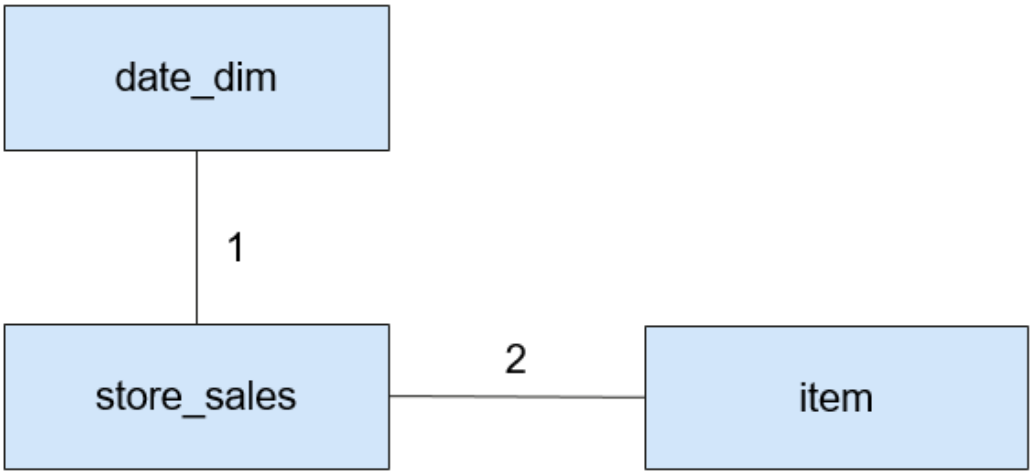
The following takes the TPC-DS Q3 as an example to describe how the CBO adjusts the join sequence:

```
select
    dt.d_year,
    item.i_brand_id brand_id,
    item.i_brand brand,
    sum(ss_ext_sales_price) sum_agg
from
    date_dim dt,
    store_sales,
    item
where
    dt.d_date_sk = store_sales.ss_sold_date_sk
    and store_sales.ss_item_sk = item.i_item_sk
```

```
   and item.i_manufact_id = 436
   and dt.d_moy = 12
group by dt.d_year , item.i_brand , item.i_brand_id
order by dt.d_year , sum_agg desc , brand_id
limit 10;
```

Statement explanation: This statement indicates that inner join is performed for three tables: table **store_sales** is a fact table with about 2,900,000,000 data entries, table **date_dim** is a dimension table with about 73,000 data entries, and table **item** is a dimension table with about 18,000 data entries. Each table has filtering conditions. **Figure 1-64** shows the join relationship.

Figure 1-64 Join relationship



The CBO must first select the tables that bring the best filtering effect for joining.

By analyzing min, max, NDV, and the number of data entries, the CBO estimates the selection rates of different dimension tables, as shown in **Table 1-13**.

Table 1-13 Data filtering

Table	Number of Original Data Entries	Number of Data Entries After Filtering	Selection Rate
date_dim	73,000	6,200	8.5%
item	18,000	19	0.1%

The selection rate can be estimated as follows: Selection rate = Number of data entries after filtering/Number of original data entries

As shown in the preceding table, the **item** table has a better filtering effect. Therefore, the CBO joins the **item** table first before joining the **date_dim** table.

Figure 1-65 shows the join process when the CBO is disabled.

Figure 1-65 Join process when the CBO is disabled

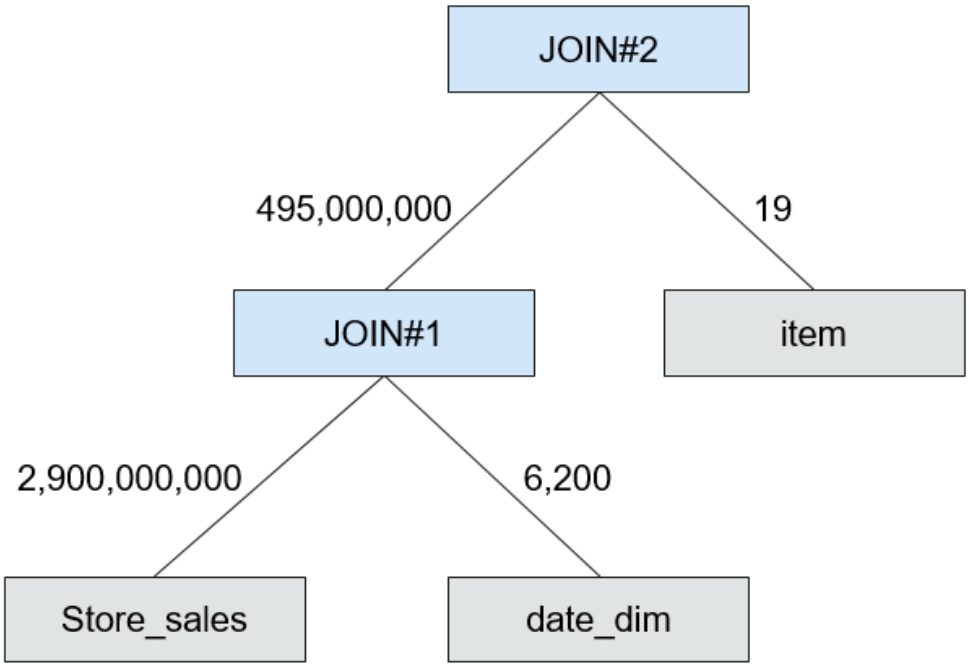


Figure 1-66 shows the join process when the CBO is enabled.

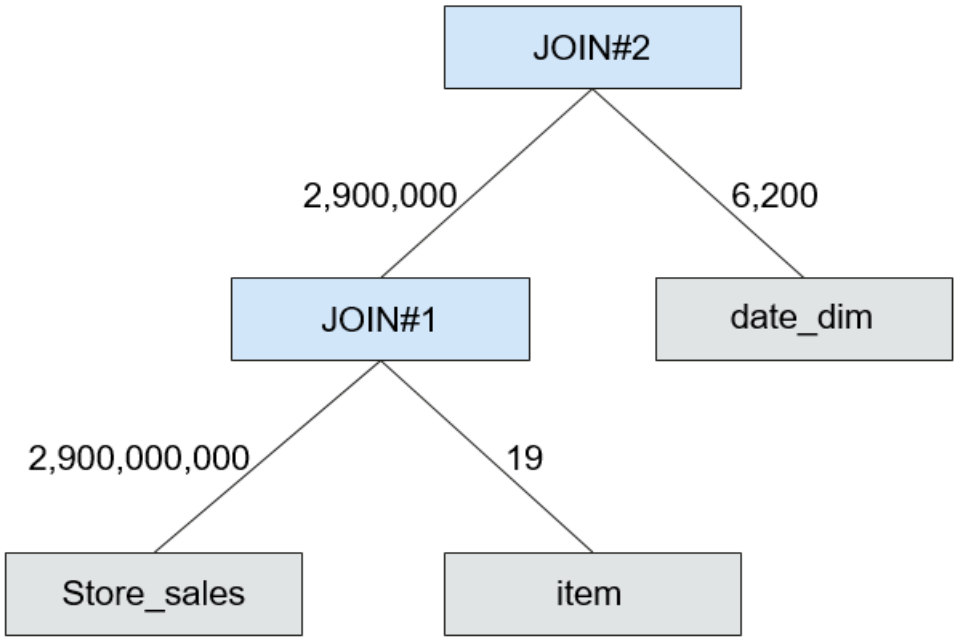
Figure 1-66 Join process when the CBO is enabled



After the CBO is enabled, the number of intermediate data entries is reduced from 495,000,000 to 2,900,000 and thus the execution time can be remarkably reduced.

1.3.12.3 Relationship Between Hive and Other Components

Relationship Between Hive and HDFS

Hive is a sub-project of Apache Hadoop, which uses HDFS as the file storage system. It parses and processes structured data with highly reliable underlying storage supported by HDFS. All data files in the Hive database are stored in HDFS, and all data operations on Hive are also performed using HDFS APIs.

Relationship Between Hive and MapReduce

Hive data computing depends on MapReduce. MapReduce is also a sub-project of Apache Hadoop and is a parallel computing framework based on HDFS. During data analysis, Hive parses HQL statements submitted by users into MapReduce tasks and submits the tasks for MapReduce to execute.

Relationship Between Hive and Tez

Tez, an open-source project of Apache, is a distributed computing framework that supports directed acyclic graphs (DAGs). When Hive uses the Tez engine to analyze data, it parses HQL statements submitted by users into Tez tasks and submits the tasks to Tez for execution.

Relationship Between Hive and DBService

MetaStore (metadata service) of Hive processes the structure and attribute information of Hive metadata, such as Hive databases, tables, and partitions. The information needs to be stored in a relational database and is managed and processed by MetaStore. In the product, the metadata of Hive is stored and maintained by the DBService component, and the metadata service is provided by the Metadata component.

Relationship Between Hive and Elasticsearch

Hive uses Elasticsearch as its extended file storage system. Hive integrates the Elasticsearch-Hadoop plug-in of Elasticsearch, creates a foreign table, and stores table data in Elasticsearch so that Hive can read and write Elasticsearch index data.

1.3.12.4 Enhanced Open Source Feature

Enhanced Open Source Feature: HDFS Colocation

HDFS Colocation is the data location control function provided by HDFS. The HDFS Colocation API stores associated data or data on which associated operations are performed on the same storage node.

Hive supports HDFS Colocation. When Hive tables are created, after the locator information is set for table files, the data files of related tables are stored on the same storage node. This ensures convenient and efficient data computing among associated tables.

Enhanced Open Source Feature: Column Encryption

Hive supports encryption of one or more columns. The columns to be encrypted and the encryption algorithm can be specified when a Hive table is created. When data is inserted into the table using the INSERT statement, the related columns are encrypted. The Hive column encryption does not support views and the Hive over HBase scenario.

The Hive column encryption mechanism supports two encryption algorithms that can be selected to meet site requirements during table creation:

- AES (the encryption class is **org.apache.hadoop.hive.serde2.AESRewriter**)
- SMS4 (the encryption class is **org.apache.hadoop.hive.serde2.SMS4Rewriter**)

Enhanced Open Source Feature: HBase Deletion

Due to the limitations of underlying storage systems, Hive does not support the ability to delete a single piece of table data. In Hive on HBase, Hive in the MRS solution supports the ability to delete a single piece of HBase table data. Using a specific syntax, Hive can delete one or more pieces of data from an HBase table.

Enhanced Open Source Feature: Row Delimiter

In most cases, a carriage return character is used as the row delimiter in Hive tables stored in text files, that is, the carriage return character is used as the terminator of a row during queries.

However, some data files are delimited by special characters, and not a carriage return character.

MRS Hive allows you to specify different characters or character combinations as row delimiters for Hive data in text files.

Enhanced Open Source Feature: HTTPS/HTTP-based REST API Switchover

WebHCat provides external REST APIs for Hive. By default, the open source community version uses the HTTP protocol.

MRS Hive supports the HTTPS protocol that is more secure, and enables switchover between the HTTP protocol and the HTTPS protocol.

Enhanced Open Source Feature: Transform Function

The Transform function is not allowed by Hive of the open source version. MRS Hive supports the configuration of the Transform function. The function is disabled by default, which is the same as that of the open source community version.

Users can modify configurations of the Transform function to enable the function. However, security risks exist when the Transform function is enabled.

Enhanced Open Source Feature: Temporary Function Creation Without ADMIN Permission

You must have **ADMIN** permission when creating temporary functions on Hive of the open source community version. MRS Hive supports the configuration of the

function for creating temporary functions with **ADMIN** permission. The function is disabled by default, which is the same as that of the open-source community version.

You can modify configurations of this function. After the function is enabled, you can create temporary functions without **ADMIN** permission.

Enhanced Open Source Feature: Database Authorization

In the Hive open source community version, only the database owner can create tables in the database. You can be granted with the **CREATE** and **SELECT** permissions on tables by MRS Hive in a database. After you are granted with the permission to query data in the database, the system automatically associates the query permission on all tables in the database.

Enhanced Open Source Feature: Column Authorization

The Hive open source community version supports only table-level permission control. MRS Hive supports column-level permission control. You can be granted with column-level permissions, such as **SELECT**, **INSERT**, and **UPDATE**.

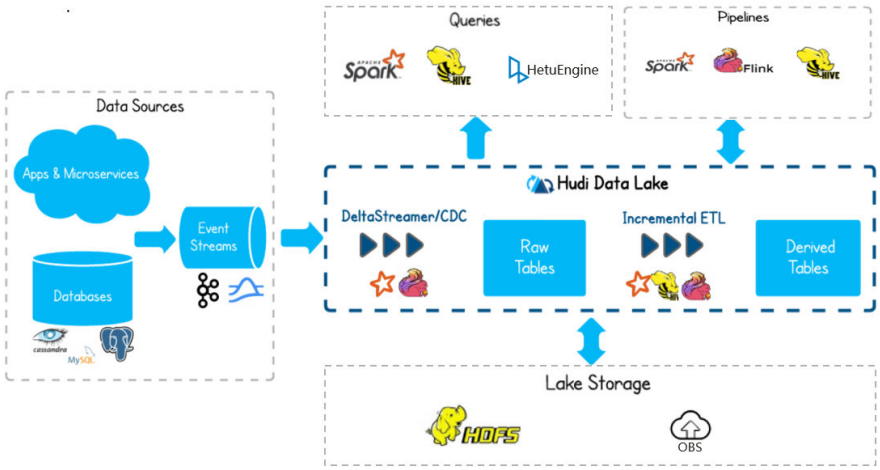
1.3.13 Hudi

Hudi is a data lake table format that provides the ability to update and delete data as well as consume new data on HDFS. It supports multiple compute engines and provides insert, update, and delete (IUD) interfaces and streaming primitives, including upsert and incremental pull, over datasets on HDFS.

NOTE

To use Hudi, ensure that the Spark service has been installed in the MRS cluster.

Figure 1-67 Basic architecture of Hudi



Feature

- The ACID transaction capability supports real-time data import to the lake and batch data import to the data lake.

- Multiple view capabilities (read-optimized view/incremental view/real-time view) enable quick data analysis.
- Multi-version concurrency control (MVCC) design supports data version backtracking.
- Automatic management of file sizes and layouts optimizes query performance and provides quasi-real-time data for queries.
- Concurrent read and write are supported. Data can be read when being written based on snapshot isolation.
- Bootstrapping is supported to convert existing tables into Hudi datasets.

Key Technologies and Advantages

- Pluggable index mechanism: Hudi provides multiple index mechanisms to quickly update and delete massive data.
- Ecosystem support: Hudi supports multiple data engines, including Hive, Spark, HetuEngine, and Flink.

Two Types of Tables Supported by Hudi

- Copy On Write

  Copy-on-write tables are also called COW tables. Parquet files are used to store data, and internal update operations need to be performed by rewriting the original Parquet files.

  - Advantage: It is efficient because only one data file in the corresponding partition needs to be read.
  - Disadvantage: During data write, a previous copy needs to be copied and then a new data file is generated based on the previous copy. This process is time-consuming. Therefore, the data read by the read request lags behind.

- Merge On Read

  Merge-on-read tables are also called MOR tables. The combination of columnar-based Parquet and row-based format Avro is used to store data. Parquet files are used to store base data, and Avro files (also called log files) are used to store incremental data.

  - Advantage: Data is written to the delta log first, and the delta log size is small. Therefore, the write cost is low.
  - Disadvantage: Files need to be compacted periodically. Otherwise, there are a large number of fragment files. The read performance is poor because delta logs and old data files need to be merged.

Hudi Supporting Three Types Of Views for Read Capabilities in Different Scenarios

- Snapshot View

  Provides the latest snapshot data of the current Hudi table. That is, once the latest data is written to the Hudi table, the newly written data can be queried through this view.

  Both COW and MOR tables support this view capability.

- Incremental View

Provides the incremental query capability. The incremental data after a specified commit can be queried. This view can be used to quickly pull incremental data.

COW tables support this view capability. MOR tables also support this view capability, but the incremental view capability disappears once the compact operation is performed.

- Read Optimized View

  Provides only the data stored in the latest Parquet file.

  This view is different for COW and MOR tables.

  For COW tables, the view capability is the same as the real-time view capability. (COW tables use only Parquet files to store data.)

  For MOR tables, only base files are accessed, and the data in the given file slices since the last compact operation is provided. It can be simply understood that this view provides only the data stored in Parquet files of MOR tables, and the data in log files is ignored. The data provided by this view may not be the latest. However, once the compact operation is performed on MOR tables, the incremental log data is merged into the base data. In this case, this view has the same capability as the real-time view.

1.3.14 IoTDB

1.3.14.1 IoTDB Basic Principles

Database for Internet of Things (IoTDB) is a software system that collects, stores, manages, and analyzes IoT time series data. Apache IoTDB uses a lightweight architecture and features high performance and rich functions.

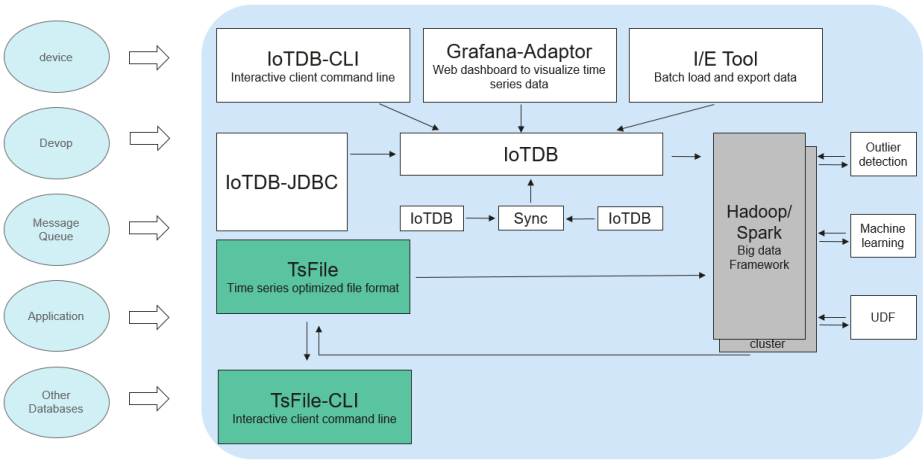
IoTDB sorts time series and stores indexes and chunks, greatly improving the query performance of time series data. IoTDB uses the Raft protocol to ensure data consistency. In time series scenarios, IoTDB pre-computes and stores data to improve analysis performance. Based on the characteristics of time series data, IoTDB provides powerful data encoding and compression capabilities. In addition, its replica mechanism ensures data security. IoTDB is deeply integrated with Apache Hadoop and Flink to meet the requirements of massive data storage, high-speed data reading, and complex data analysis in the industrial IoT field.

IoTDB Architecture

The IoTDB suite consists of multiple components to provide a series of functions such as data collection, data writing, data storage, data query, data visualization, and data analysis.

Figure 1-68 shows the overall application architecture after all components of the IoTDB suite are used. IoTDB refers to the time series database component in the suite.

Figure 1-68 IoTDB architecture

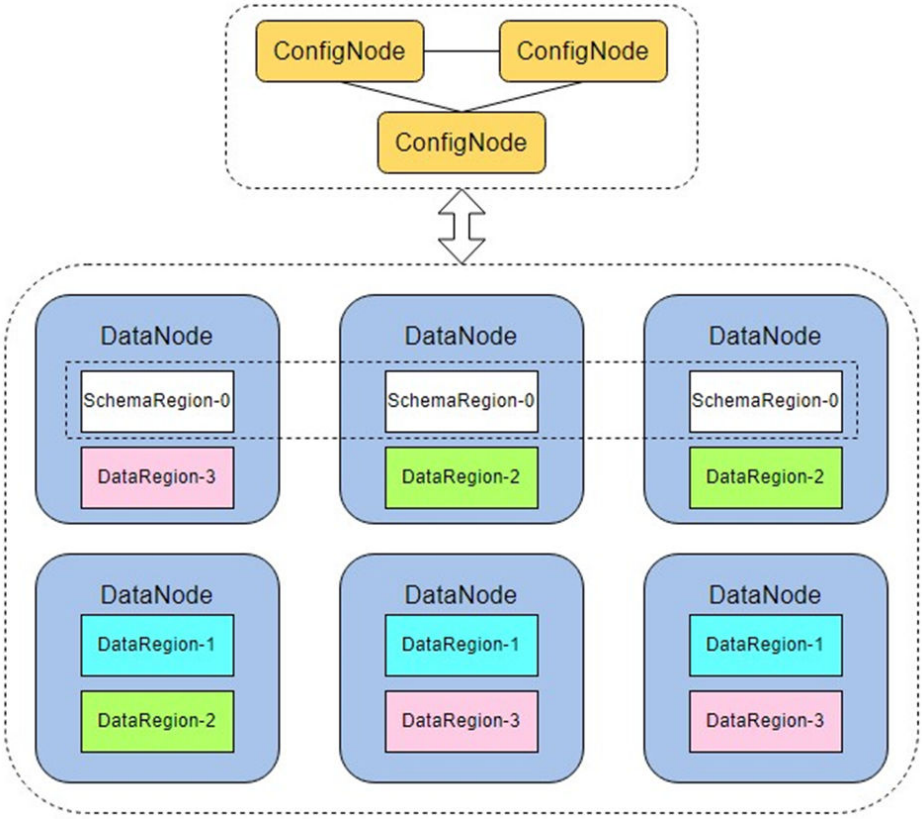


- Users can use Java Database Connectivity (JDBC) or Session to import the time series data and system status data (such as server load, CPU usage and memory usage) collected from device sensors, as well as time series data in message queues, applications, or other databases, to the local or remote IoTDB. Users can also directly write the preceding data into a local TsFile file or a TsFile file in the HDFS.
- Users can write TsFile files to the HDFS to implement data processing tasks such as exception detection and machine learning on the Hadoop or Flink data processing platform.
- The TsFile-Hadoop or TsFile-Flink connector can be used to allow Hadoop or Flink to process the TsFile files written to the HDFS or local host.
- The analysis result can be written back to a TsFile in the same way.
- IoTDB and TsFile also provide client tools to meet users' requirements for viewing and writing data in SQL, script, and graphical formats.

The IoTDB service includes two roles: IoTDBServer (DataNode) and ConfigNode. The role name DataNode of the community edition has the same name as the HDFS role. DataNode is renamed IoTDBServer.

- ConfigNode: management role, which is responsible for DataNode data sharding and load balancing.
- IoTDBServer (DataNode): storage role, which is responsible for storing, querying, and writing data.

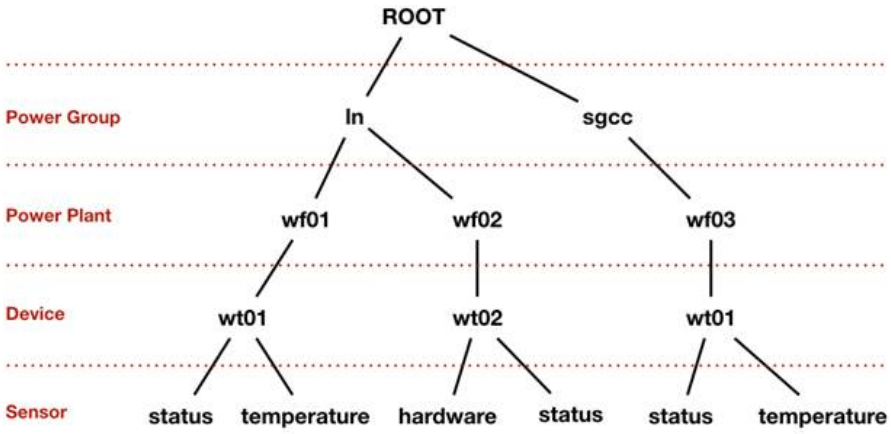
Figure 1-69 IoTDB distributed architecture



IoTDB Principles

Based on the attribute hierarchy, attribute coverage, and subordinate relationships between data, the IoTDB data model can be represented as the attribute hierarchy, as shown in **Figure 1-70**. The hierarchy is as follows: power group layer - power plant layer - device layer - sensor layer. **ROOT** is a root node, and each node at the sensor layer is a leaf node. According to the IoTDB syntax, the path from **ROOT** to a leaf node is separated by a dot (.). The complete path is used to name a time series in the IoTDB. For example, the time series name corresponding to the path on the left in the following figure is **ROOT.ln.wf01.wt01.status**.

Figure 1-70 IoTDB data model



1.3.14.2 Relationship Between IoTDB and Other Components

The IoTDB stores data locally, so it does not depend on any other component for storage. However, in a security cluster environment, IoTDB depends on the KrbServer component for Kerberos authentication.

1.3.14.3 IoTDB Enhanced Open Source Features

Visualization

- Visualized O&M covers installation, uninstallation, one-click start and stop, configurations, clients, monitoring, alarms, health checks, and logs.
- Visualized permission management does not require background command line operations and supports read and write permission control at the database and table levels.
- Visualized log level configuration dynamically takes effect, supports visualized download and retrieval, and supports log audit.

Security Hardening

User authentication supports Kerberos authentication and SSL encryption, which are compatible with the community authentication mode.

Ecosystem Interconnection

On the basis of native capabilities, the cluster interconnection with MQTT is enhanced.

Enterprise-Level Features

In addition to native capabilities, disk hot swap, backup, and restoration capabilities are enhanced.

Lakehouse

Supports cross-source federation. HetuEngine can be used with HBase and Hive for converged analysis and query, eliminating the need for data transfer.

1.3.15 Kafka

1.3.15.1 Kafka Basic Principles

Kafka is an open source, distributed, partitioned, and replicated commit log service. Kafka is publish-subscribe messaging, rethought as a distributed commit log. It provides features similar to Java Message Service (JMS) but another design. It features message endurance, high throughput, distributed methods, multi-client support, and real time. It applies to both online and offline message consumption, such as regular message collection, website activeness tracking, aggregation of statistical system operation data (monitoring data), and log collection. These scenarios engage large amounts of data collection for Internet services.

Kafka Structure

Producers publish data to topics, and consumers subscribe to the topics and consume messages. A broker is a server in a Kafka cluster. For each topic, the Kafka cluster maintains partitions for scalability, parallelism, and fault tolerance. Each partition is an ordered, immutable sequence of messages that is continually appended to - a commit log. Each message in a partition is assigned a sequential ID, which is called offset.

Figure 1-71 Kafka architecture

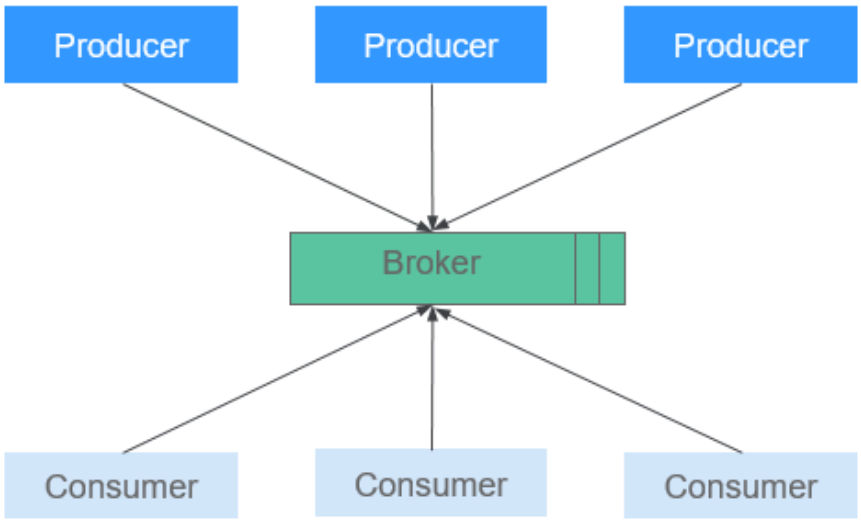


Table 1-14 Kafka architecture description

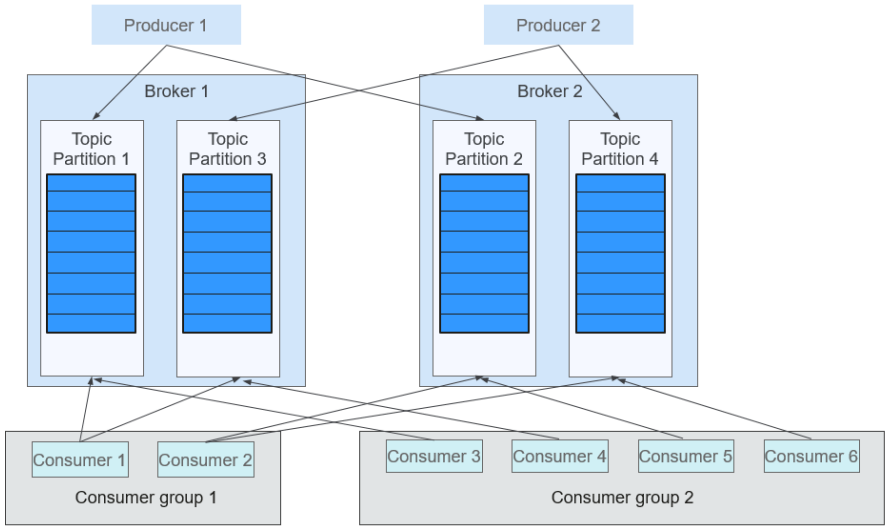
Name	Description
Broker	A broker is a server in a Kafka cluster.

Name	Description
Topic	A topic is a category or feed name to which messages are published. A topic can be divided into multiple partitions, which can act as a parallel unit.
Partition	A partition is an ordered, immutable sequence of messages that is continually appended to - a commit log. The messages in the partitions are each assigned a sequential ID number called the offset that uniquely identifies each message within the partition.
Producer	Producers publish messages to a Kafka topic.
Consumer	Consumers subscribe to topics and process the feed of published messages.

Figure 1-72 shows the relationships between modules.

Figure 1-72 Relationships between Kafka modules



Consumers label themselves with a consumer group name, and each message published to a topic is delivered to one consumer instance within each subscribing consumer group. If all the consumer instances belong to the same consumer group, loads are evenly distributed among the consumers. As shown in the preceding figure, Consumer1 and Consumer2 work in load-sharing mode; Consumer3, Consumer4, Consumer5, and Consumer6 work in load-sharing mode. If all the consumer instances belong to different consumer groups, messages are broadcast to all consumers. As shown in the preceding figure, the messages in Topic 1 are broadcast to all consumers in Consumer Group1 and Consumer Group2.

Principle

- **Message Reliability**

  When a Kafka broker receives a message, it stores the message on a disk persistently. Each partition of a topic has multiple replicas stored on different broker nodes. If one node is faulty, the replicas on other nodes can be used.

- **High Throughput**

  Kafka provides high throughput in the following ways:

  – Messages are written into disks instead of being cached in the memory, fully utilizing the sequential read and write performance of disks.

  – The use of zero-copy eliminates I/O operations.

  – Data is sent in batches, improving network utilization.

  – Each topic is divided in to multiple partitions, which increases concurrent processing. Concurrent read and write operations can be performed between multiple producers and consumers. Producers send messages to specified partitions based on the algorithm used.

- **Message Subscribe-Notify Mechanism**

  Consumers subscribe to interested topics and consume data in pull mode. Consumers can choose the consumption mode, such as batch consumption, repeated consumption, and consumption from the end, and control the message pulling speed based on actual situation. Consumers need to maintain the consumption records by themselves.

- **Scalability**

  When broker nodes are added to expand the Kafka cluster capacity, the newly added brokers register with ZooKeeper. After the registration is successful, procedures and consumers can sense the change in a timely manner and make related adjustment.

Open Source Features

- Reliability

  Message processing methods such as **At-Least Once**, **At-Most Once**, and **Exactly Once** are provided. The message processing status is maintained by consumers. Kafka needs to work with the application layer to implement **Exactly Once**.

- High throughput

  High throughput is provided for message publishing and subscription.

- Persistence

  Messages are stored on disks and can be used for batch consumption and real-time application programs. Data persistence and replication prevent data loss.

- Distribution

  A distributed system is easy to be expanded externally. All producers, brokers, and consumers support the deployment of multiple distributed clusters. Systems can be scaled without stopping the running of software or shutting down the machines.

Kafka UI

Kafka UI provides Kafka web services, displays basic information about functional modules such as brokers, topics, partitions, and consumers in a Kafka cluster, and provides operation entries for common Kafka commands. Kafka UI replaces Kafka Manager to provide secure Kafka web services that comply with security specifications.

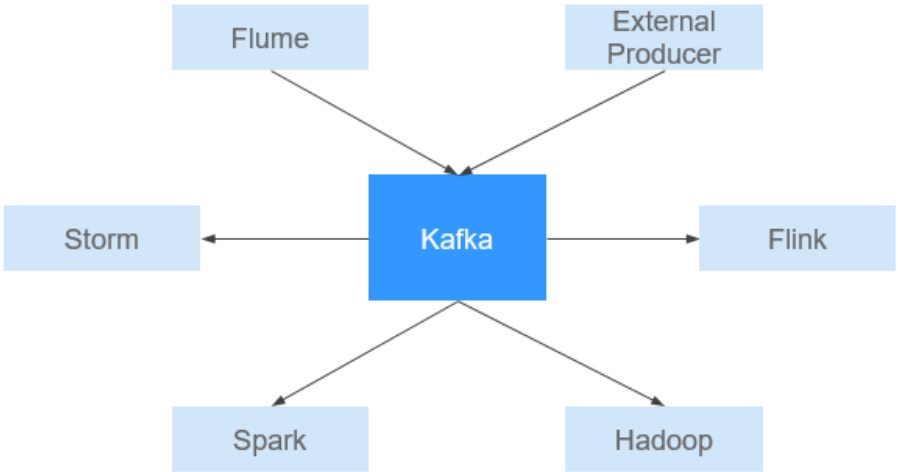
You can perform the following operations on Kafka UI:

- Check cluster status (topics, consumers, offsets, partitions, replicas, and nodes).
- Redistribute partitions in the cluster.
- Create a topic with optional topic configurations.
- Delete a topic (supported when **delete.topic.enable** is set to **true** for the Kafka service).
- Add partitions to an existing topic.
- Update configurations for an existing topic.
- Optionally enable JMX polling for broker-level and topic-level metrics.

1.3.15.2 Relationship Between Kafka and Other Components

As a message publishing and subscription system, Kafka provides high-speed data transmission methods for data transmission between different subsystems of the FusionInsight platform. It can receive external messages in a real-time manner and provides the messages to the online and offline services for processing. The following figure shows the relationship between Kafka and other components.

Figure 1-73 Relationship with Other Components



1.3.15.3 Kafka Enhanced Open Source Features

Kafka Enhanced Open Source Features

- Monitors the following topic-level metrics:
  - Topic Input Traffic
  - Topic Output Traffic
  - Topic Rejected Traffic
  - Number of Failed Fetch Requests Per Second
  - Number of Failed Produce Requests Per Second
  - Number of Topic Input Messages Per Second
  - Number of Fetch Requests Per Second
  - Number of Produce Requests Per Second
- Queries the mapping between broker IDs and node IP addresses. On Linux clients, **kafka-broker-info.sh** can be used to query the mapping between broker IDs and node IP addresses.

1.3.16 KafkaManager

KafkaManager is a tool for managing Apache Kafka and provides GUI-based metric monitoring and management of Kafka clusters.

KafkaManager supports the following operations:

- Manage multiple Kafka clusters.
- Easy inspection of cluster states (topics, consumers, offsets, partitions, replicas, and nodes)
- Run preferred replica election.
- Generate partition assignments with option to select brokers to use.
- Run reassignment of partition (based on generated assignments).
- Create a topic with optional topic configurations (Multiple Kafka cluster versions are supported).
- Delete a topic (only supported on 0.8.2+ and **delete.topic.enable=true** is set in broker configuration).
- Batch generate partition assignments for multiple topics with option to select brokers to use.
- Batch run reassignment of partitions for multiple topics.
- Add partitions to an existing topic.
- Update configurations for an existing topic.
- Optionally enable JMX polling for broker-level and topic-level metrics.
- Optionally filter out consumers that do not have ids/ owner / & offsets/ directories in ZooKeeper.

1.3.17 KrbServer and LdapServer

1.3.17.1 KrbServer and LdapServer Principles

Overview

To manage the access control permissions on data and resources in a cluster, it is recommended that the cluster be installed in security mode. In security mode, a client application must be authenticated and a secure session must be established before the application accesses any resource in the cluster. MRS uses KrbServer to provide Kerberos authentication for all components, implementing a reliable authentication mechanism.

LdapServer supports Lightweight Directory Access Protocol (LDAP) and provides the capability of storing user and user group data for Kerberos authentication.

Architecture

The security authentication function for user login depends on Kerberos and LDAP.

Figure 1-74 Security authentication architecture

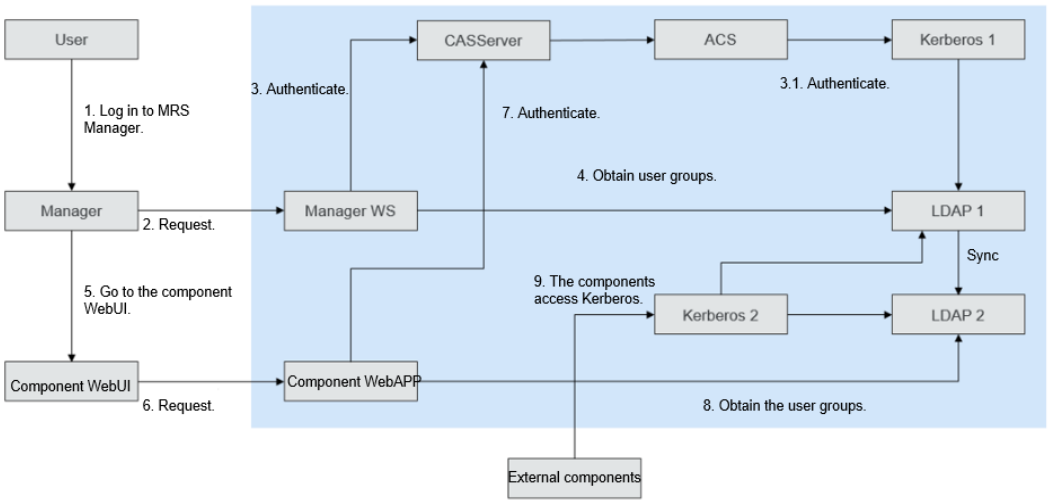


Figure 1-74 includes three scenarios:

- Logging in to the MRS Manager Web UI

  The authentication architecture includes steps 1, 2, 3, and 4.
- Logging in to a component web UI

  The authentication architecture includes steps 5, 6, 7, and 8.
- Accessing between components

  The authentication architecture includes step 9.

Table 1-15 Key modules

Connection Name	Description
Manager	Cluster Manager

Connection Name	Description
Manager WS	WebBrowser
Kerberos1	KrbServer (management plane) service deployed in MRS Manager, that is, OMS Kerberos
Kerberos2	KrbServer (service plane) service deployed in the cluster
LDAP1	LdapServer (management plane) service deployed in MRS Manager, that is, OMS LDAP
LDAP2	LdapServer (service plane) service deployed in the cluster

Data operation mode of Kerberos1 in LDAP: The active and standby instances of LDAP1 and the two standby instances of LDAP2 can be accessed in load balancing mode. Data write operations can be performed only in the active LDAP1 instance. Data read operations can be performed in LDAP1 or LDAP2.

Data operation mode of Kerberos2 in LDAP: Data read operations can be performed in LDAP1 and LDAP2. Data write operations can be performed only in the active LDAP1 instance.

Principle

Kerberos authentication

Figure 1-75 Authentication process

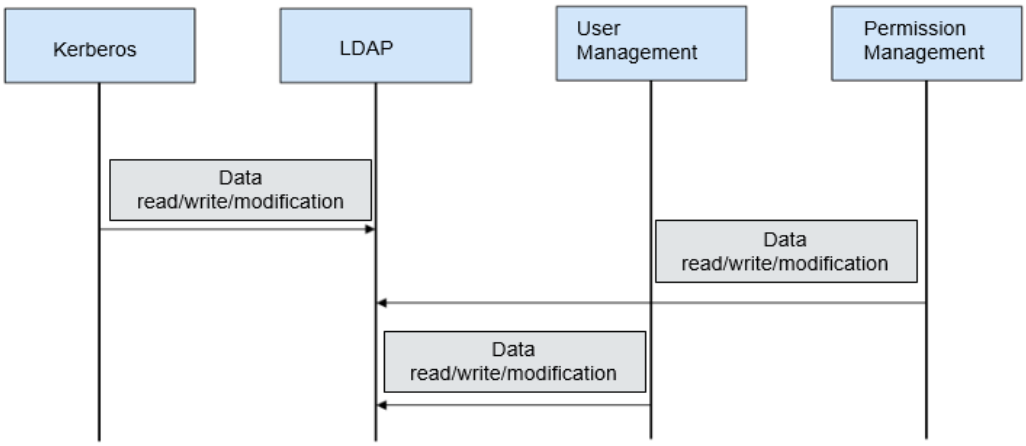
Figure 1-76 Data modification process



LDAP data synchronization

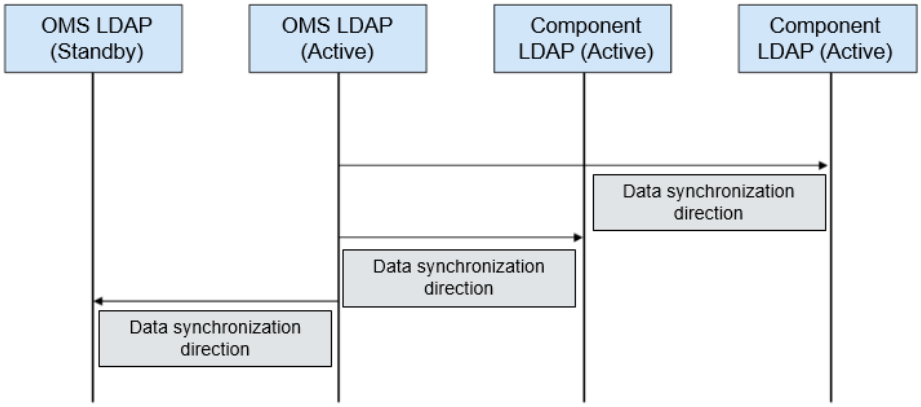
- OMS LDAP data synchronization before cluster installation

  Figure 1-77 OMS LDAP data synchronization

  
  Data synchronization direction before cluster installation: Data is synchronized from the active OMS LDAP to the standby OMS LDAP.

- LDAP data synchronization after cluster installation

Figure 1-78 LDAP data synchronization



Data synchronization direction after cluster installation: Data is synchronized from the active OMS LDAP to the standby OMS LDAP, standby component LDAP, and standby component LDAP.

1.3.17.2 KrbServer and LdapServer Enhanced Open Source Features

Enhanced open-source features of KrbServer and LdapServer: intra-cluster service authentication

In an MRS cluster that uses the security mode, mutual access between services is implemented based on the Kerberos security architecture. When a service (such as HDFS) in the cluster is to be started, the corresponding sessionkey (keytab, used for identity authentication of the application) is obtained from Kerberos. If another service (such as YARN) needs to access HDFS and add, delete, modify, or query data in HDFS, the corresponding TGT and ST must be obtained for secure access.

Enhanced Open-Source Features of KrbServer and LdapServer: Application Development Authentication

MRS components provide application development interfaces for customers or upper-layer service product clusters. During application development, a cluster in security mode provides specified application development authentication interfaces to implement application security authentication and access. For example, the UserGroupInformation class provided by the hadoop-common API provides multiple security authentication APIs.

- **setConfiguration()** is used to obtain related configuration and set parameters such as global variables.
- **loginUserFromKeytab():** is used to obtain TGT interfaces.

Enhanced Open-Source Features of KrbServer and LdapServer: Cross-System Mutual Trust

MRS provides the mutual trust function between two Managers to implement data read and write operations between systems.

1.3.18 Loader

1.3.18.1 Loader Basic Principles

Loader is developed based on the open source Sqoop component. It is used to exchange data and files between MRS and relational databases and file systems. Loader can import data from relational databases or file servers to the HDFS and HBase components, or export data from HDFS and HBase to relational databases or file servers.

A Loader model consists of Loader Client and Loader Server, as shown in **Figure 1-79**.

Figure 1-79 Loader model

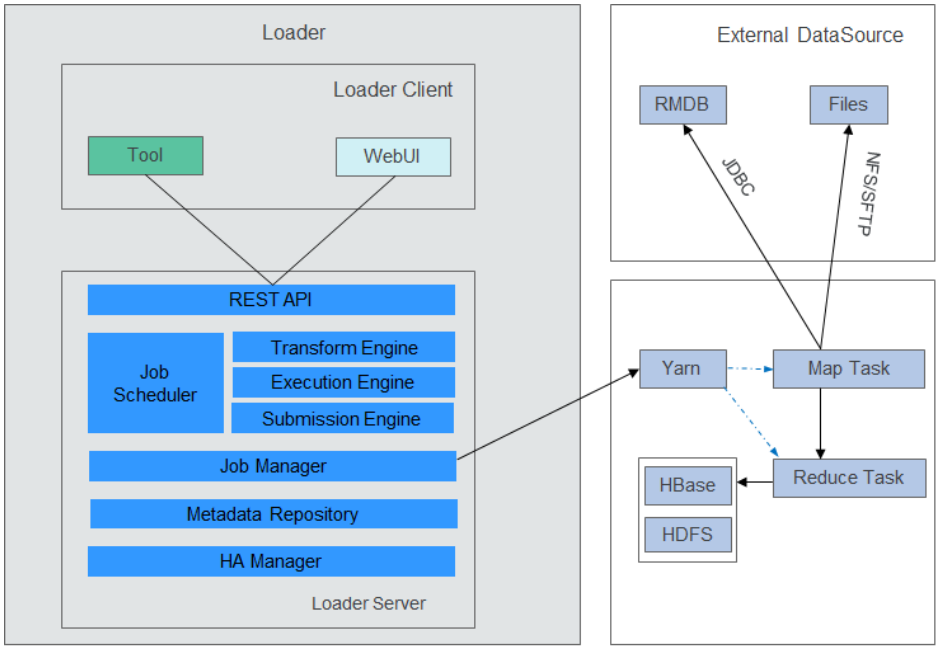


Table 1-16 describes the functions of each module shown in the preceding figure.

Table 1-16 Components of the Loader model

Module	Description
Loader Client	Loader client. It provides two interfaces: web UI and CLI.
Loader Server	Loader server. It processes operation requests sent from the client, manages connectors and metadata, submits MapReduce jobs, and monitors MapReduce job status.
REST API	It provides a Representational State Transfer (RESTful) APIs (HTTP + JSON) to process the operation requests sent from the client.

Module	Description
Job Scheduler	Simple job scheduler. It periodically executes Loader jobs.
Transform Engine	Data transformation engine. It supports field combination, string cutting, and string reverse.
Execution Engine	Loader job execution engine. It executes Loader jobs in MapReduce manner.
Submission Engine	Loader job submission engine. It submits Loader jobs to MapReduce.
Job Manager	It manages Loader jobs, including creating, querying, updating, deleting, activating, deactivating, starting, and stopping jobs.
Metadata Repository	Metadata repository. It stores and manages data about Loader connectors, transformation procedures, and jobs.
HA Manager	It manages the active/standby status of Loader Server processes. The Loader Server has two nodes that are deployed in active/standby mode.

Loader imports or exports jobs in parallel using MapReduce jobs. Some job import or export may involve only the Map operations, while some may involve both Map and Reduce operations.

Loader implements fault tolerance using MapReduce. Jobs can be rescheduled upon a job execution failure.

- **Importing data to HBase**

  When the Map operation is performed for MapReduce jobs, Loader obtains data from an external data source.

  When a Reduce operation is performed for a MapReduce job, Loader enables the same number of Reduce tasks based on the number of Regions. The Reduce tasks receive data from Map tasks, generate HFiles by Region, and store the HFiles in a temporary directory of HDFS.

  When a MapReduce job is submitted, Loader migrates HFiles from the temporary directory to the HBase directory.

- **Importing Data to HDFS**

  When a Map operation is performed for a MapReduce job, Loader obtains data from an external data source and exports the data to a temporary directory (named *export directory*-**ldtmp**).

  When a MapReduce job is submitted, Loader migrates data from the temporary directory to the output directory.

- **Exporting data to a relational database**

  When a Map operation is performed for a MapReduce job, Loader obtains data from HDFS or HBase and inserts the data to a temporary table (Staging Table) through the Java DataBase Connectivity (JDBC) API.

When a MapReduce job is submitted, Loader migrates data from the temporary table to a formal table.

- **Exporting data to a file system**

  When a Map operation is performed for a MapReduce job, Loader obtains data from HDFS or HBase and writes the data to a temporary directory of the file server.

  When a MapReduce job is submitted, Loader migrates data from the temporary directory to a formal directory.

1.3.18.2 Relationship Between Loader and Other Components

The components that interact with Loader include HDFS, HBase, MapReduce, and ZooKeeper. Loader works as a client to use certain functions of these components, such as storing data to HDFS and HBase and reading data from HDFS and HBase tables. In addition, Loader functions as an MapReduce client to import or export data.

1.3.18.3 Loader Enhanced Open Source Features

Loader Enhanced Open-Source Feature: Data Import and Export

Loader is developed based on Sqoop. In addition to the Sqoop functions, Loader has the following enhanced features:

- Provides data conversion functions.
- Supports GUI-based configuration conversion.
- Imports data from an SFTP/FTP server to HDFS/OBS.
- Imports data from an SFTP/FTP server to an HBase table.
- Imports data from an SFTP/FTP server to a Phoenix table.
- Imports data from an SFTP/FTP server to a Hive table.
- Exports data from HDFS/OBS to an SFTP/FTP server.
- Exports data from an HBase table to an SFTP/FTP server.
- Exports data from a Phoenix table to an SFTP/FTP server.
- Imports data from a relational database to an HBase table.
- Imports data from a relational database to a Phoenix table.
- Imports data from a relational database to a Hive table.
- Exports data from an HBase table to a relational database.
- Exports data from a Phoenix table to a relational database.
- Imports data from an Oracle partitioned table to HDFS/OBS.
- Imports data from an Oracle partitioned table to an HBase table.
- Imports data from an Oracle partitioned table to a Phoenix table.
- Imports data from an Oracle partitioned table to a Hive table.
- Exports data from HDFS/OBS to an Oracle partitioned table.
- Exports data from HBase to an Oracle partitioned table.
- Exports data from a Phoenix table to an Oracle partitioned table.

- Imports data from HDFS to an HBase table, a Phoenix table, and a Hive table in the same cluster.
- Exports data from an HBase table and a Phoenix table to HDFS/OBS in the same cluster.
- Imports data to an HBase table and a Phoenix table by using **bulkload** or **put list**.
- Imports all types of files from an SFTP/FTP server to HDFS. The open source component Sqoop can import only text files.
- Exports all types of files from HDFS/OBS to an SFTP server. The open source component Sqoop can export only text files and SequenceFile files.
- Supports file coding format conversion during file import and export. The supported coding formats include all formats supported by Java Development Kit (JDK).
- Retains the original directory structure and file names during file import and export.
- Supports file combination during file import and export. For example, if a large number of files are to be imported, these files can be combined into *n* files (*n* can be configured).
- Supports file filtering during file import and export. The filtering rules support wildcards and regular expressions.
- Supports batch import and export of ETL tasks.
- Supports query by page and key word and group management of ETL tasks.
- Provides floating IP addresses for external components.

1.3.19 Manager

1.3.19.1 Manager Basic Principles

Overview

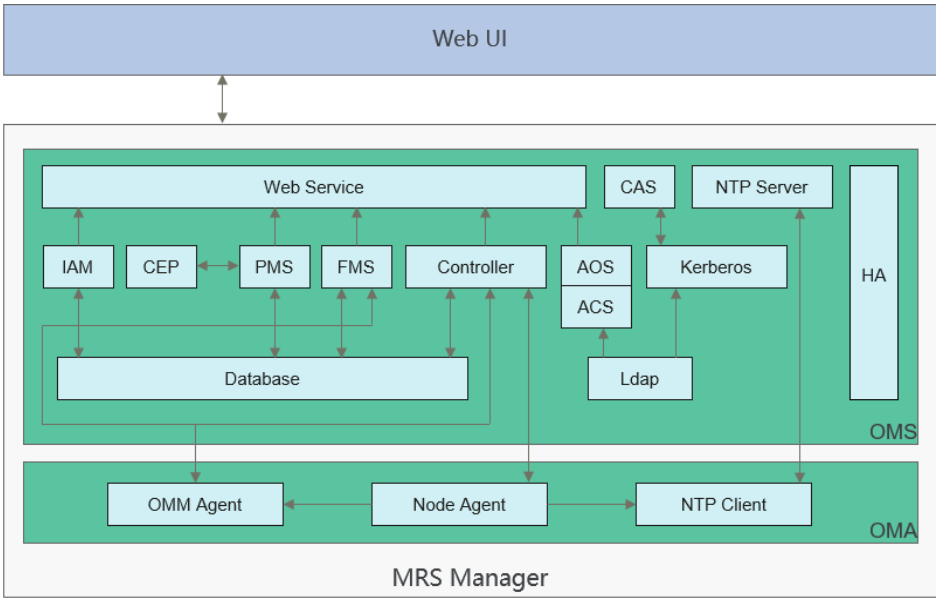
Manager is the O&M management system of MRS and provides unified cluster management capabilities for services deployed in clusters.

Manager provides functions such as performance monitoring, alarms, user management, permission management, auditing, service management, health check, and log collection.

Architecture

Figure 1-80 shows the overall logical architecture of FusionInsight Manager.

Figure 1-80 Manager logical architecture



Manager consists of OMS and OMA.

- OMS: serves as management node in the O&M system. There are two OMS nodes deployed in active/standby mode.
- OMA: managed node in the O&M system. Generally, there are multiple OMA nodes.

Table 1-17 describes the modules shown in **Figure 1-80**.

Table 1-17 Service module description

Module	Description
Web Service	A web service deployed under Tomcat, providing HTTPS API of Manager. It is used to access Manager through the web browser. In addition, it provides the northbound access capability based on the Syslog and SNMP protocols.
OMS	Management node of the O&M system. Generally, there are two OMS nodes that work in active/standby mode.
OMA	Managed node in the O&M system. Generally, there are multiple OMA nodes.

Module	Description
Controller	The control center of Manager. It can converge information from all nodes in the cluster and display it to MRS cluster administrators, as well as receive from MRS cluster administrators, and synchronize information to all nodes in the cluster according to the operation instruction range. Control process of Manager. It implements various management actions: 1. The web service delivers various management actions (such as installation, service startup and stop, and configuration modification) to Controller. 2. Controller decomposes the command and delivers the action to each Node Agent, for example, starting a service involves multiple roles and instances. 3. Controller is responsible for monitoring the implementation of each action.
Node Agent	Node Agent exists on each cluster node and is an enabler of Manager on a single node. ● Node Agent represents all the components deployed on the node to interact with Controller, implementing convergence from multiple nodes of a cluster to a single node. ● Node Agent enables Controller to perform all operations on the components deployed on the node. It allows Controller functions to be implemented. Node Agent sends heartbeat messages to Controller at an interval of 3 seconds. The interval cannot be configured.
IAM	Records audit logs. Each non-query operation on the Manager UI has a related audit log.
PMS	The performance monitoring module. It collects the performance monitoring data on each OMA and provides the query function.
CEP	Convergence function module. For example, the used disk space of all OMAs is collected as a performance indicator.
FMS	Alarm module. It collects and queries alarms on each OMA.
OMM Agent	Agent for performance monitoring and alarm reporting on the OMA. It collects performance monitoring data and alarm data on Agent Node.
CAS	Unified authentication center. When a user logs in to the web service, CAS authenticates the login. The browser automatically redirects the user to the CAS through URLs.
AOS	Permission management module. It manages the permissions of users and user groups.

Module	Description
ACS	User and user group management module. It manages users and user groups to which users belong.
Kerberos	LDAP is deployed in OMS and a cluster, respectively. ● OMS Kerberos provides the single sign-on (SSO) and authentication between Controller and Node Agent. ● Kerberos in the cluster provides the user security authentication function for components. The service name is **KrbServer**, which contains two role instances: – KerberosServer: is an authentication server that provides security authentication for MRS. – KerberosAdmin: manages processes of Kerberos users.
Ldap	LDAP is deployed in OMS and a cluster, respectively. ● OMS LDAP provides data storage for user authentication. ● The LDAP in the cluster functions as the backup of the OMS LDAP. The service name is **LdapServer** and the role instance is **SlapdServer**.
Database	Manager database used to store logs and alarms.
HA	HA management module that manages the active and standby OMSs.
NTP Server NTP Client	It synchronizes the system clock of each node in the cluster.

1.3.19.2 Manager Key Features

Key Feature: Unified Alarm Monitoring

Manager provides the visualized and convenient alarm monitoring function. Users can quickly obtain key cluster performance indicators, evaluate cluster health status, customize performance indicator display, and convert indicators to alarms. Manager can monitor the running status of all components and report alarms in real time when faults occur. The online help on the GUI allows you to view performance counters and alarm clearance methods to quickly rectify faults.

Key Feature: Unified User Permission Management

Manager provides permission management of components in a unified manner.

Manager introduces the concept of role and uses role-based access control (RBAC) to manage system permissions. It centrally displays and manages scattered permission functions of each component in the system and organizes the permissions of each component in the form of permission sets (roles) to form a unified system permission concept. By doing so, common users cannot obtain internal permission management details, and permissions become easy for MRS

cluster administrators to manage, greatly facilitating permission management and improving user experience.

Key Feature: SSO

Single sign-on (SSO) is provided between the Manager web UI and component web UI as well as for integration between MRS and third-party systems.

This function centrally manages and authenticates Manager users and component users. The entire system uses LDAP to manage users and uses Kerberos for authentication. A set of Kerberos and LDAP management mechanisms are used between the OMS and components. SSO (including single sign-on and single sign-out) is implemented through CAS. With SSO, users can easily switch tasks between the Manager web UI, component web UIs, and third-party systems, without switching to another user.

NOTE

- To ensure security, the CAS Server can retain a ticket-granting ticket (TGT) used by a user only for 20 minutes.
- If a user does not perform any operation on the page (including on the Manager web UI and component web UIs) within 20 minutes, the page is automatically locked.

Key Feature: Automatic Health Check and Inspection

Manager provides users with automatic inspection on system running environments and helps users check and audit system running health by one click, ensuring correct system running and lowering system operation and maintenance costs. After viewing inspection results, you can export reports for archiving and fault analysis.

Key Feature: Tenant Management

Manager introduces the multi-tenant concept. The CPU, memory, and disk resources of a cluster can be integrated into a set. The set is called a tenant. A mode involving different tenants is called multi-tenant mode.

Manager provides the multi-tenant function, supports a level-based tenant model and allows tenants to be added and deleted dynamically, achieving resource isolation. As a result, it can dynamically manage and configure the computing resources and the storage resources of tenants.

- The computing resources indicate tenants' Yarn task queue resources. The task queue quota can be modified, and the task queue usage status and statistics can be viewed.
- The storage resources can be stored on HDFS. You can add and delete the HDFS storage directories of tenants, and set the quotas of file quantity and the storage space of the directories.

As a unified tenant management platform of MRS, MRS Manager allows users to create and manage tenants in clusters based on service requirements.

- Roles, computing resources, and storage resources are automatically created when tenants are created. By default, all permissions of the new computing resources and storage resources are allocated to a tenant's roles.

- After you have modified the tenant's computing or storage resources, permissions of the tenant's roles are automatically updated.

Manager also provides the multi-instance function so that users can use the HBase, Hive, or Spark alone in the resource control and service isolation scenario. The multi-instance function is disabled by default and can be manually enabled.

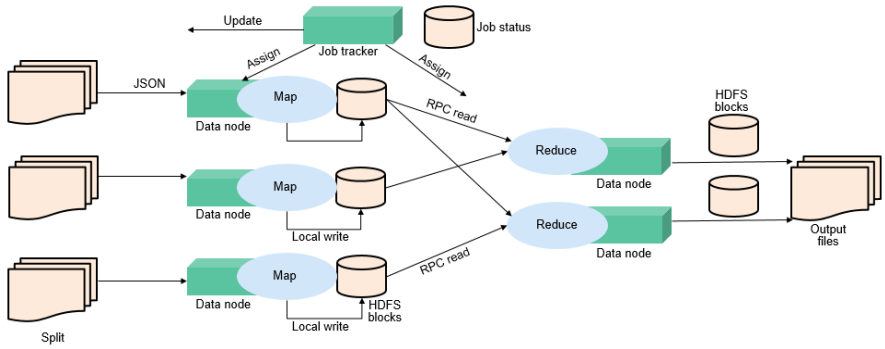
1.3.20 MapReduce

1.3.20.1 MapReduce Basic Principles

MapReduce is the core of Hadoop. As a software architecture proposed by Google, MapReduce is used for parallel computing of large-scale datasets (larger than 1 TB). The concepts "Map" and "Reduce" and their main thoughts are borrowed from functional programming language and also borrowed from the features of vector programming language.

Current software implementation is as follows: Specify a Map function to map a series of key-value pairs into a new series of key-value pairs, and specify a Reduce function to ensure that all values in the mapped key-value pairs share the same key.

Figure 1-81 Distributed batch processing engine

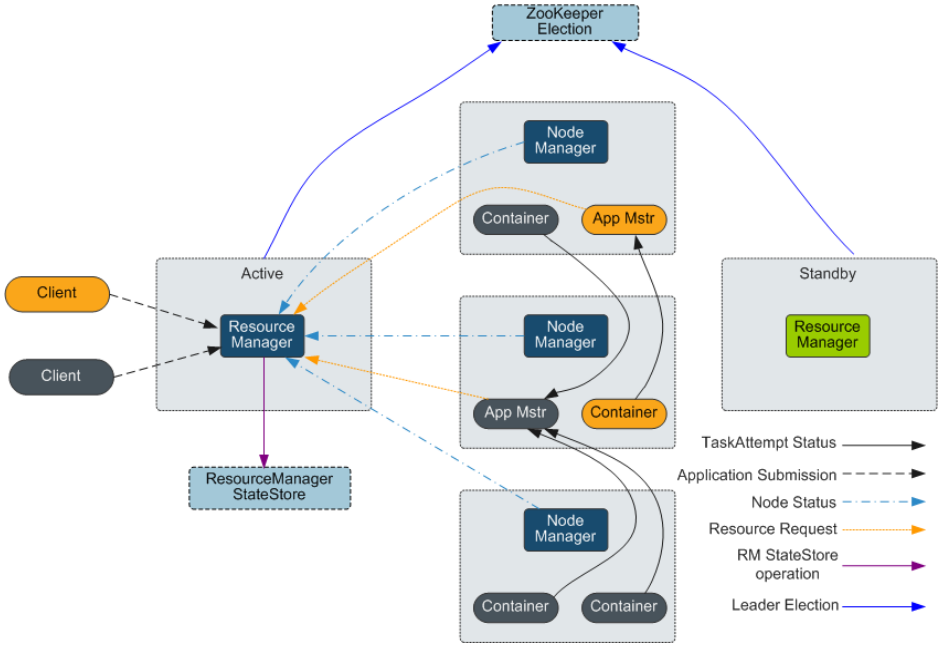


MapReduce is a software framework for processing large datasets in parallel. The root of MapReduce is the Map and Reduce functions in functional programming. The Map function accepts a group of data and transforms it into a key-value pair list. Each element in the input domain corresponds to a key-value pair. The Reduce function accepts the list generated by the Map function, and then shrinks the key-value pair list based on the keys. MapReduce divides a task into multiple parts and allocates them to different devices for processing. In this way, the task can be finished in a distributed environment instead of a single powerful server.

MapReduce structure

As shown in **Figure 1-82**, MapReduce is integrated into YARN through the Client and ApplicationMaster interfaces of YARN, and uses YARN to apply for computing resources.

Figure 1-82 Basic architecture of Apache YARN and MapReduce



1.3.20.2 Relationship Between MapReduce and Other Components

Relationship Between MapReduce and HDFS

- HDFS features high fault tolerance and high throughput, and can be deployed on low-cost hardware for storing data of applications with massive data sets.
- MapReduce is a programming model used for parallel computation of large data sets (larger than 1 TB). Data computed by MapReduce comes from multiple data sources, such as Local FileSystem, HDFS, and databases. Most data comes from the HDFS. The high throughput of HDFS can be used to read massive data. After being computed, data can be stored in HDFS.

Relationship Between MapReduce and Yarn

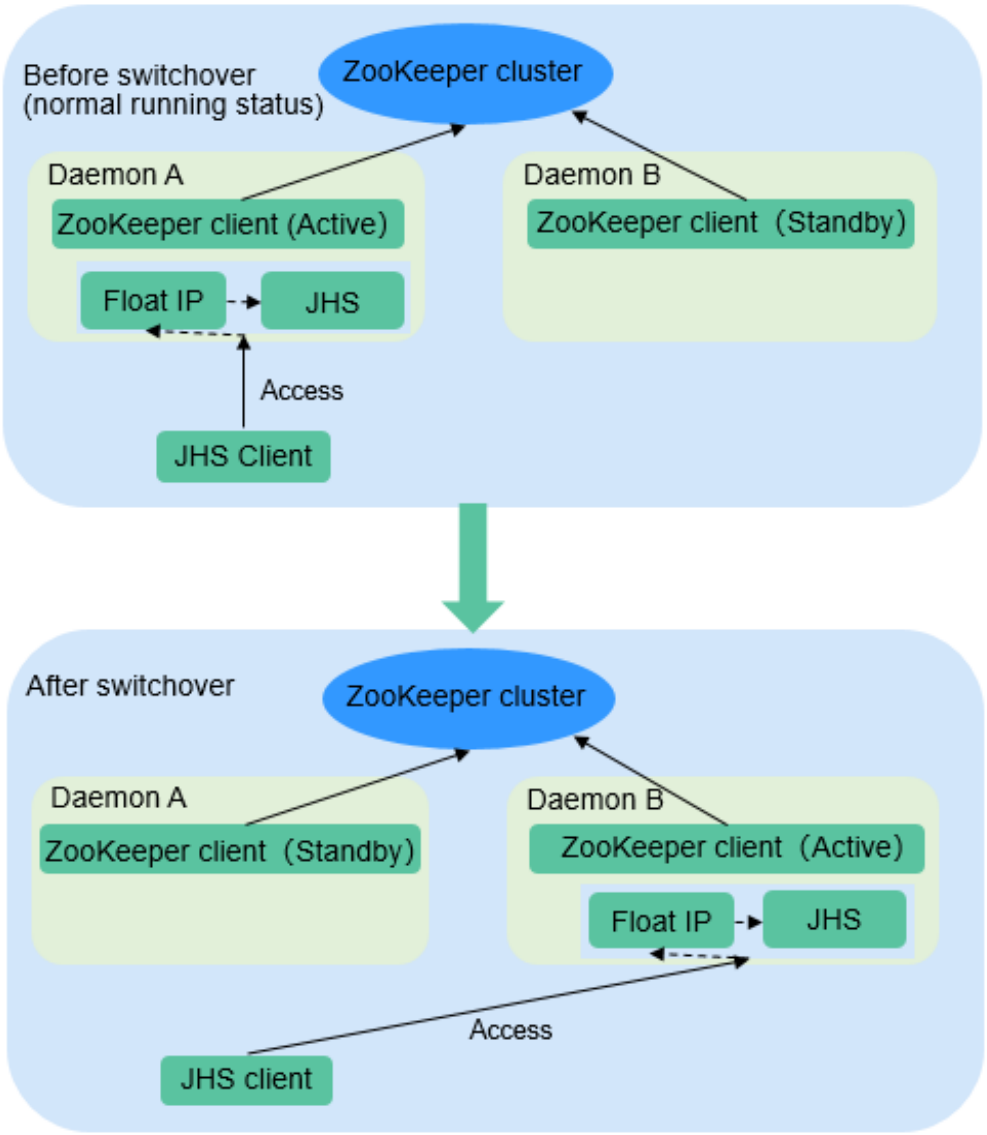
MapReduce is a computing framework running on Yarn, which is used for batch processing. MRv1 is implemented based on MapReduce in Hadoop 1.0, which is composed of programming models (new and old programming APIs), running environment (JobTracker and TaskTracker), and data processing engine (MapTask and ReduceTask). This framework is still weak in scalability, fault tolerance (JobTracker SPOF), and compatibility with multiple frameworks. (Currently, only the MapReduce computing framework is supported.) MRv2 is implemented based on MapReduce in Hadoop 2.0. The source code reuses MRv1 programming models and data processing engine implementation, and the running environment is composed of ResourceManager and ApplicationMaster. ResourceManager is a brand new resource manager system, and ApplicationMaster is responsible for cutting MapReduce job data, assigning tasks, applying for resources, scheduling tasks, and tolerating faults.

1.3.20.3 MapReduce Enhanced Open Source Features

MapReduce Enhanced Open-Source Feature: JobHistoryServer HA

JobHistoryServer (JHS) is the server used to view historical MapReduce task information. Currently, the open source JHS supports only single-instance services. JHS HA can solve the problem that an application fails to access the MapReduce API when SPOFs occur on the JHS, which causes the application fails to be executed. This greatly improves the high availability of the MapReduce service.

Figure 1-83 Status transition of the JobHistoryServer HA active/standby switchover



JobHistoryServer High Availability

- ZooKeeper is used to implement active/standby election and switchover.
- JHS uses the floating IP address to provide services externally.

- Both the JHS single-instance and HA deployment modes are supported.
- Only one node starts the JHS process at a time point to prevent multiple JHS operations from processing the same file.
- You can perform scale-out, scale-in, instance migration, upgrade, and health check.

Enhanced Open Source Feature: Improving MapReduce Performance by Optimizing the Merge/Sort Process in Specific Scenarios

The figure below shows the workflow of a MapReduce task.

Figure 1-84 MapReduce job

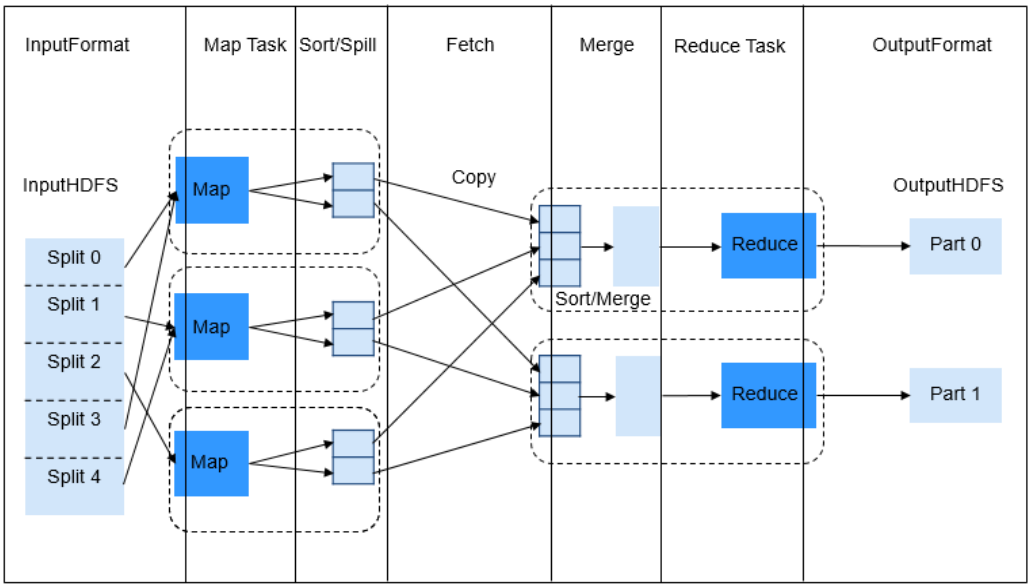


Figure 1-85 MapReduce job execution flow

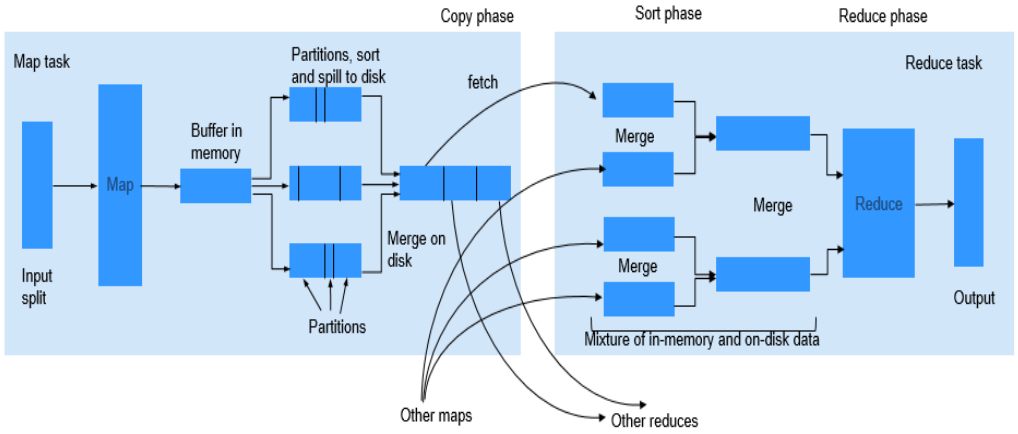

The Reduce process is divided into three different steps: Copy, Sort (actually supposed to be called Merge), and Reduce. In Copy phase, Reducer tries to fetch the output of Maps from NodeManagers and store it on Reducer either in memory

or on disk. Shuffle (Sort and Merge) phase then begins. All the fetched map outputs are being sorted, and segments from different map outputs are merged before being sent to Reducer. When a job has a large number of maps to be processed, the shuffle process is time-consuming. For specific tasks (for example, SQL tasks such as hash join and hash aggregation), sorting is not mandatory during the shuffle process. However, the sorting is required by default in the shuffle process.

This feature is enhanced by using the MapReduce API, which can automatically close the Sort process for such tasks. When the sorting is disabled, the API directly merges the fetched Maps output data and sends the data to Reducer. This greatly saves time, and significantly improves the efficiency of SQL tasks.

Enhanced Open Source Feature: Small Log File Problem Solved After Optimization of MR History Server

After the job running on Yarn is executed, NodeManager uses LogAggregationService to collect and send generated logs to HDFS and deletes them from the local file system. After the logs are stored to HDFS, they are managed by MR HistoryServer. LogAggregationService will merge local logs generated by containers to a log file and upload it to the HDFS, reducing the number of log files to some extent. However, in a large-scale and busy cluster, there will be excessive log files on HDFS after long-term running.

For example, if there are 20 nodes, about 18 million log files are generated within the default clean-up period (15 days), which occupy about 18 GB of the memory of a NameNode and slow down the HDFS system response.

Only the reading and deletion are required for files stored on HDFS. Therefore, Hadoop Archives can be used to periodically archive the directory of collected log files.

Archiving Logs

The AggregatedLogArchiveService module is added to MR HistoryServer to periodically check the number of files in the log directory. When the number of files reaches the threshold, AggregatedLogArchiveService starts an archiving task to archive log files. After archiving, it deletes the original log files to reduce log files on HDFS.

Cleaning Archived Logs

Hadoop Archives does not support deletion in archived files. Therefore, the entire archive log package must be deleted upon log clean-up. The latest log generation time is obtained by modifying the AggregatedLogDeletionService module. If all log files meet the clean-up requirements, the archive log package can be deleted.

Browsing Archived Logs

Hadoop Archives allows URI-based access to file content in the archive log package. Therefore, if MR History Server detects that the original log files do not exist during file browsing, it directly redirects the URI to the archive log package to access the archived log file.

NOTE

- This function invokes Hadoop Archives of HDFS for log archiving. Because the execution of an archiving task by Hadoop Archives is to run an MR application. Therefore, after an archiving task is executed, an MR execution record is added.
- This function of archiving logs is based on the log collection function. Therefore, this function is valid only when the log collection function is enabled.

1.3.21 MemArtsCC

1.3.21.1 MemArtsCC Basic Principles

MemArtsCC is a distributed caching service designed for the architecture with decoupled storage and compute. It adopts a lightweight architecture and is deployed in a compute cluster. It prefetches data from remote object storage to provide high-speed access to these data, accelerating execution of compute tasks.

MemArtsCC shards objects on remote object storage (OBS) and creates indexes, greatly improving the performance of reading cached data. ZooKeeper is used to make service discovery lightweight and provides ultra-high availability. The lifecycle management of sharded data is based on the LRU algorithm.

Main Features

- The decentralized architecture enables all instances to provide same service capabilities.
- With a lightweight design, the resource usage is extremely low.
- MemArtsCC is decoupled from applications and therefore is transparent to them and can be used without adaptation.
- MemArtsCC ensures high availability in case of node failures.

MemArtsCC Structure

There are CCSideCar and CCWorker roles of MemArtsCC instances.

In an architecture with decoupled storage and compute, data of computing and analytics applications such as Spark and Hive is stored in OBS. In a MemArtsCC cluster, a service instance is called a worker. Workers cache some or all of the object data in OBS to local persistent storage (SDD/HDD). When an application reads an object through the MemArtsCC SDK, the application reads sharded data from a specific worker based on the shard index. If the cache is hit, the worker returns the shards. If the cache is not hit, the application directly reads data from OBS. The worker asynchronously loads the shards that are not hit to local storage for subsequent use.

Figure 1-86 MemArtsCC structure

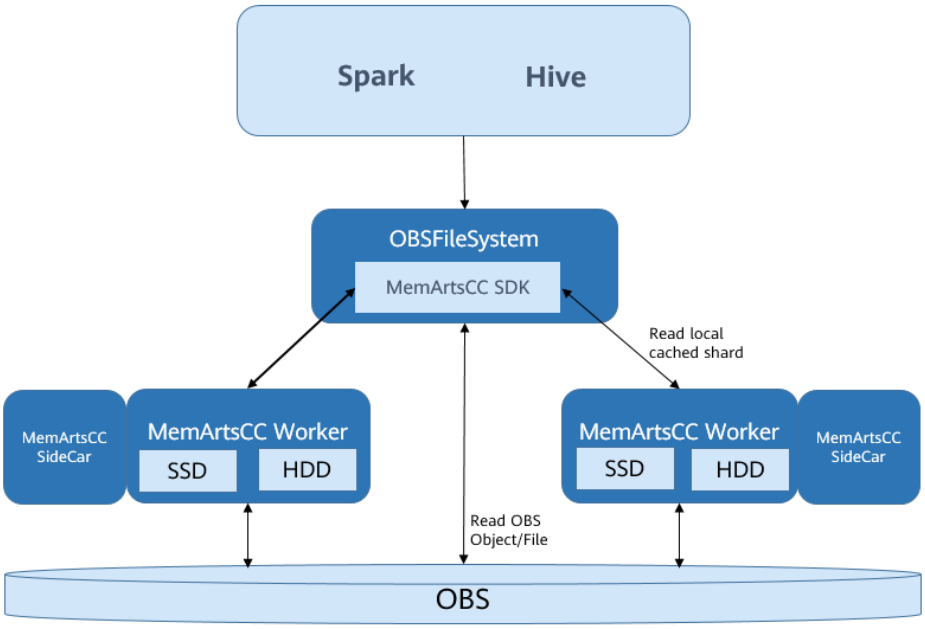

Table 1-18 Structure

Name	Description
MemArtsCC SDK	SDK used by OBSA, a Hadoop client plug-in on the FS client, to access OBS server objects.
CCSideCar	The management plane service monitors MemArtsCC, collects data, delivers configurations, and starts and stops the service.
CCWorker	The data plane service reads/writes, stores, and deletes data cached by MemArtsCC.

1.3.21.2 Relationships Between MemArtsCC and Other Components

OBS

OBS provides a new InputStream: OBSMemArtsCCInputStream. This InputStream reads data from the MemArtsCC cluster deployed on the compute side to reduce OBS server pressure and improve data read performance.

MemArtsCC persistently stores data to the storage (SSD) on the compute side. OBS interconnects with MemArtsCC to:

1. Improve the data access performance of the architecture where storage and compute are decoupled.

   The local storage of MemArtsCC avoids the cross-network access of hotspot data. This accelerates the data reads of OBS upper-layer applications.

2. Reduce the pressure on the OBS server.

   MemArtsCC stores hotspot data in the compute cluster to reduce the bandwidth pressure of the OBS server.

Spark

Spark reads data from OBS. OBS reads data from MemArtsCC. If data is hit in the local cache, the data is read directly. Otherwise, the data is prefetched.

Hive

Hive reads data from OBS. OBS reads data from MemArtsCC. If data is hit in the local cache, the data is read directly. Otherwise, the data is prefetched.

HetuEngine

HetuEngine reads data from OBS. OBS reads data from MemArtsCC. If data is hit in the local cache, the data is read directly. Otherwise, the data is prefetched.

1.3.22 Oozie

1.3.22.1 Oozie Basic Principles

Introduction to Oozie

Oozie is an open-source workflow engine that is used to schedule and coordinate Hadoop jobs.

Architecture

The Oozie engine is a web application integrated into Tomcat by default. Oozie uses PostgreSQL databases.

Oozie provides an Ext-based web console, through which users can view and monitor Oozie workflows. Oozie provides an external REST web service API for the Oozie client to control workflows (such as starting and stopping operations), and orchestrate and run Hadoop MapReduce tasks. For details, see **Figure 1-87**.

Figure 1-87 Oozie architecture

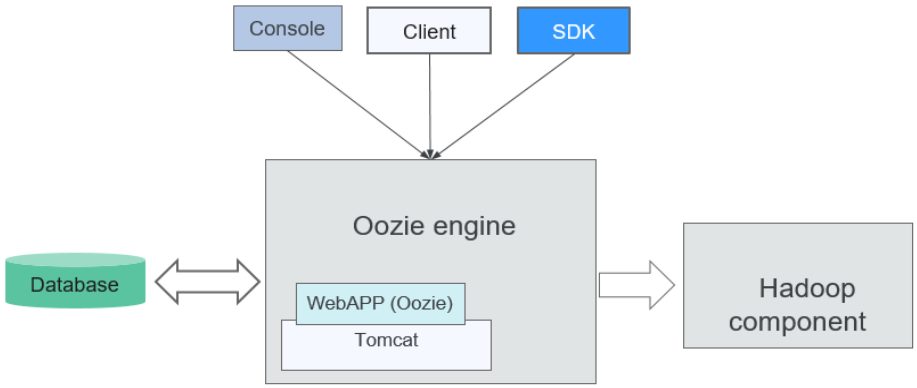

Table 1-19 describes the functions of each module shown in **Figure 1-87**.

Table 1-19 Architecture description

Connection Name	Description
Console	Allows users to view and monitor Oozie workflows.
Client	Controls workflows, including submitting, starting, running, planting, and restoring workflows, through APIs.
SDK	Is short for software development kit. An SDK is a set of development tools used by software engineers to establish applications for particular software packages, software frameworks, hardware platforms, and operating systems.
Database	PostgreSQL database
WebApp (Oozie)	Functions as the Oozie server. It can be deployed on a built-in or an external Tomcat container. Information recorded by WebApp (Oozie) including logs is stored in the PostgreSQL database.
Tomcat	A free open-source web application server
Hadoop components	Underlying components, such as MapReduce and Hive, that execute the workflows orchestrated by Oozie.

Principle

Oozie is a workflow engine server that runs MapReduce workflows. It is also a Java web application running in a Tomcat container.

Oozie workflows are constructed using Hadoop Process Definition Language (HPDL). HPDL is an XML-defined language, similar to JBoss jBPM Process Definition Language (jPDL). An Oozie workflow consists of the Control Node and Action Node.

- Control Node controls workflow orchestration, such as **start**, **end**, **error**, **decision**, **fork**, and **join**.
- An Oozie workflow contains multiple Action Nodes, such as MapReduce and Java.

  All Action Nodes are deployed and run in Direct Acyclic Graph (DAG) mode. Therefore, Action Nodes run in direction. That is, the next Action Node can run only when the running of the previous Action Node ends. When one Action Node ends, the remote server calls back the Oozie interface. Then Oozie executes the next Action Node of workflow in the same manner until all Action Nodes are executed (execution failures are counted).

Oozie workflows provide various types of Action Nodes, such as MapReduce, Hadoop distributed file system (HDFS), Secure Shell (SSH), Java, and Oozie sub-flows, to support a wide range of business requirements.

1.3.22.2 Oozie Enhanced Open Source Features

Enhanced Open Source Feature: Improved Security

Provides roles of administrator and common users to support Oozie permission management.

Supports single sign-on and sign-out, HTTPS access, and audit logs.

1.3.23 Ranger

1.3.23.1 Ranger Basic Principles

Apache Ranger offers a centralized security management framework and supports unified authorization and auditing. It manages fine grained access control over Hadoop and related components, such as HDFS, Hive, HBase, and Kafka. You can use the front-end web UI console provided by Ranger to configure policies to control users' access to these components.

Figure 1-88 shows the Ranger architecture.

Figure 1-88 Ranger structure

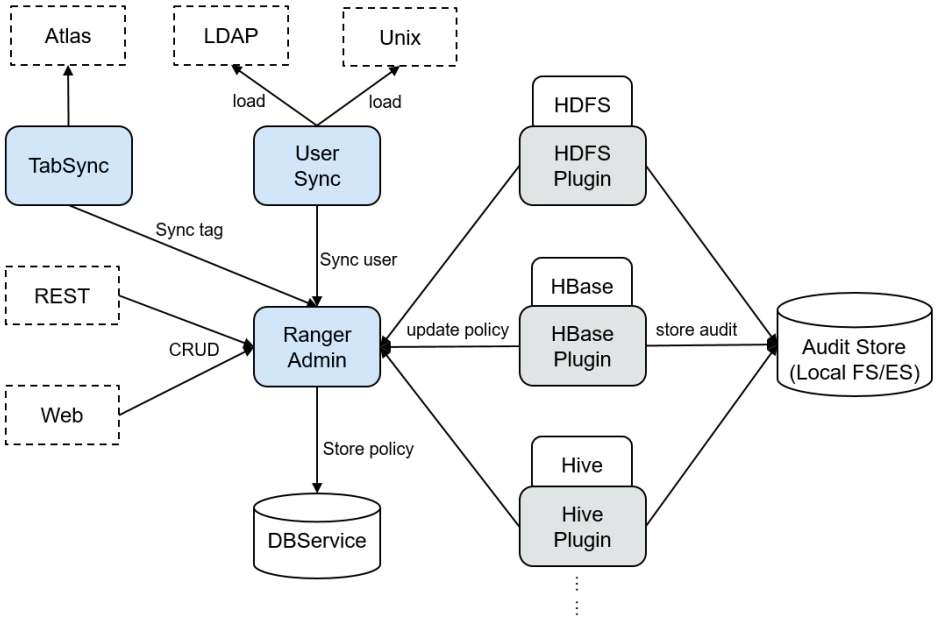

Table 1-20 Architecture description

Connection Name	Description
RangerAdmin	Provides a WebUI and RESTful API to manage policies, users, and auditing.
UserSync	Periodically synchronizes user and user group information from an external system and writes the information to RangerAdmin.

Connection Name	Description
TagSync	Periodically synchronizes tag information from the external Atlas service and writes the tag information to RangerAdmin.

Ranger Principles

- Ranger Plugins

  Ranger provides policy-based access control (PBAC) plug-ins to replace the original authentication plug-ins of the components. Ranger plug-ins are developed based on the authentication interface of the components. Users set permission policies for specified services on the Ranger web UI. Ranger plug-ins periodically update policies from the RangerAdmin and caches them in the local file of the component. When a client request needs to be authenticated, the Ranger plug-in matches the user carried in the request with the policy and then returns an accept or reject message.

- UserSync User Synchronization

  UserSync periodically synchronizes data from LDAP/Unix to RangerAdmin. In security mode, data is synchronized from LDAP. In non-security mode, data is synchronized from Unix. By default, the incremental synchronization mode is used. In each synchronization period, UserSync updates only new or modified users and user groups. When a user or user group is deleted, UserSync does not synchronize the change to RangerAdmin. That is, the user or user group is not deleted from the RangerAdmin. To improve performance, UserSync does not synchronize user groups to which no user belongs to RangerAdmin.

- Unified auditing

  Ranger plug-ins can record audit logs. Currently, audit logs can be stored in local files or Elasticsearch. By default, audit logs are stored in local files. To enable Elasticsearch storage, enable it by following the instructions provided in the guide and query the audit details of the corresponding components on the Audit tab page of Ranger WebUI.

- High reliability

  Ranger supports two RangerAdmins working in active/active mode. Two RangerAdmins provide services at the same time. If either RangerAdmin is faulty, Ranger continues to work.

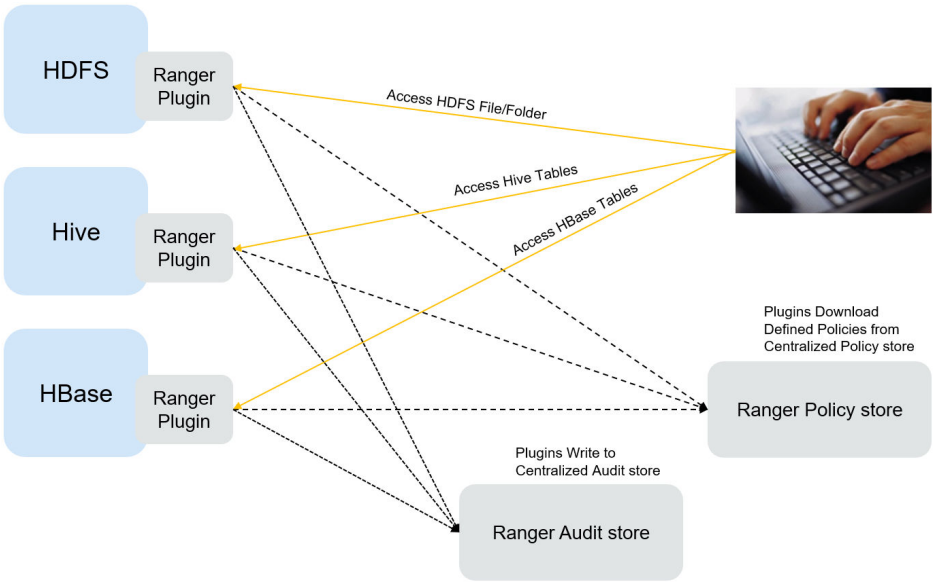
- High performance

  Ranger provides the Load-Balance capability. When a user accesses Ranger WebUI using a browser, the Load-Balance automatically selects the RangerAdmin with the lightest load to provide services.

1.3.23.2 Relationship Between Ranger and Other Components

Ranger provides PABC-based authentication plug-ins for components to run on their servers. Ranger currently supports authentication for the following components like HDFS, YARN, Hive, HBase, Kafka, Elasticsearch, and Spark. More components will be supported in the future.

Figure 1-89 Relationship Between Ranger and Other Components



1.3.24 Spark

1.3.24.1 Spark Basic Principles

Description

Spark is a memory-based distributed computing framework. In iterative computation scenarios, the computing capability of Spark is 10 to 100 times higher than MapReduce, because data is stored in memory when being processed. Spark can use HDFS as the underlying storage system, enabling users to quickly switch to Spark from MapReduce. Spark provides one-stop data analysis capabilities, such as the streaming processing in small batches, offline batch processing, SQL query, and data mining. Users can seamlessly use these functions in a same application. For details about the new open-source features of Spark, see **Spark Open Source New Features**.

Features of Spark are as follows:

- Improves the data processing capability through distributed memory computing and directed acyclic graph (DAG) execution engine. The delivered performance is 10 to 100 times higher than that of MapReduce.
- Supports multiple development languages (Scala/Java/Python) and dozens of highly abstract operators to facilitate the construction of distributed data processing applications.
- Builds data processing stacks using SQL, Streaming, MLlib, and GraphX to provide one-stop data processing capabilities.
- Fits into the Hadoop ecosystem, allowing Spark applications to run on Standalone, Mesos, or Yarn, enabling access of multiple data sources such as HDFS, HBase, and Hive, and supporting smooth migration of the MapReduce application to Spark.

Architecture

Figure 1-90 describes the Spark architecture and **Table 1-21** lists the Spark modules.

Figure 1-90 Spark architecture

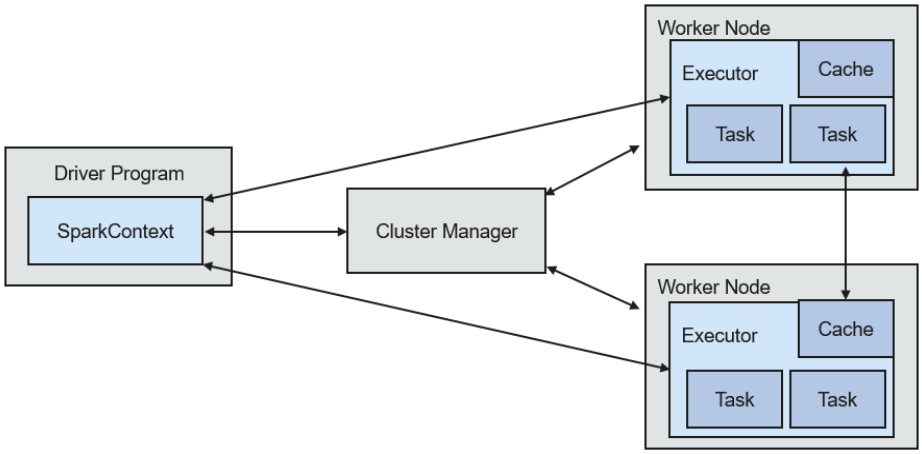


Table 1-21 Basic concepts

Module	Description
Cluster Manager	Cluster manager manages resources in the cluster. Spark supports multiple cluster managers, including Mesos, Yarn, and the Standalone cluster manager that is delivered with Spark. By default, Spark clusters adopt the Yarn cluster manager.
Application	Spark application. It consists of one Driver Program and multiple executors.
Deploy Mode	Deployment in cluster or client mode. In cluster mode, the driver runs on a node inside the cluster. In client mode, the driver runs on the client (outside the cluster).
Driver Program	The main process of the Spark application. It runs the **main()** function of an application and creates SparkContext. It is used for parsing applications, generating stages, and scheduling tasks to executors. Usually, SparkContext represents Driver Program.
Executor	A process started on a Work Node. It is used to execute tasks, and manage and process the data used in applications. A Spark application usually contains multiple executors. Each executor receives commands from the driver and executes one or multiple tasks.
Worker Node	A node that starts and manages executors and resources in a cluster.

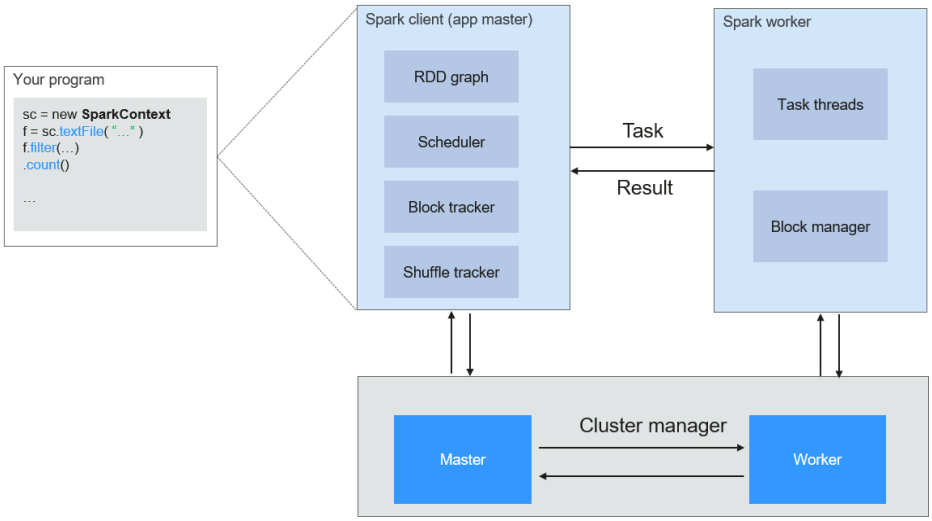
Module	Description
Job	A job consists of multiple concurrent tasks. One action operator (for example, a collect operator) maps to one job.
Stage	Each job consists of multiple stages. Each stage is a task set, which is separated by Directed Acyclic Graph (DAG).
Task	A task carries the computation unit of the service logics. It is the minimum working unit that can be executed on the Spark platform. An application can be divided into multiple tasks based on the execution plan and computation amount.

Spark Principle

Figure 1-91 describes the application running architecture of Spark.

1. An application is running in the cluster as a collection of processes. Driver coordinates the running of the application.
2. To run an application, Driver connects to the cluster manager (such as Standalone, Mesos, and Yarn) to apply for the executor resources, and start ExecutorBackend. The cluster manager schedules resources between different applications. Driver schedules DAGs, divides stages, and generates tasks for the application at the same time.
3. Then, Spark sends the codes of the application (the codes transferred to SparkContext, which is defined by JAR or Python) to an executor.
4. After all tasks are finished, the running of the user application is stopped.

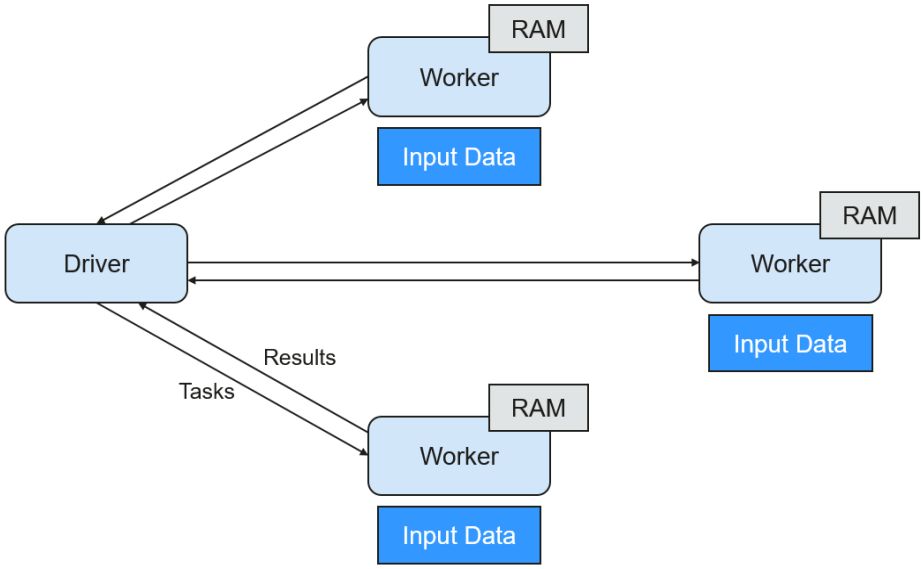
Figure 1-91 Spark application running architecture



Spark uses Master and Worker modes, as shown in **Figure 1-92**. A user submits an application on the Spark client, and then the scheduler divides a job into multiple tasks and sends the tasks to each Worker for execution. Each Worker reports the

computation results to Driver (Master), and then the Driver aggregates and returns the results to the client.

Figure 1-92 Spark Master-Worker mode



Note the following about the architecture:

- Applications are isolated from each other.

  Each application has an independent executor process, and each executor starts multiple threads to execute tasks in parallel. Each driver schedules its own tasks, and different application tasks run on different JVMs, that is, different executors.
- Different Spark applications do not share data, unless data is stored in the external storage system such as HDFS.
- You are advised to deploy the Driver program in a location that is close to the Worker node because the Driver program schedules tasks in the cluster. For example, deploy the Driver program on the network where the Worker node is located.

Spark on YARN can be deployed in two modes:

- In Yarn-cluster mode, the Spark driver runs inside an ApplicationMaster process which is managed by Yarn in the cluster. After the ApplicationMaster is started, the client can exit without interrupting service running.
- In Yarn-client mode, Driver runs in the client process, and the ApplicationMaster process is used only to apply for requesting resources from Yarn.

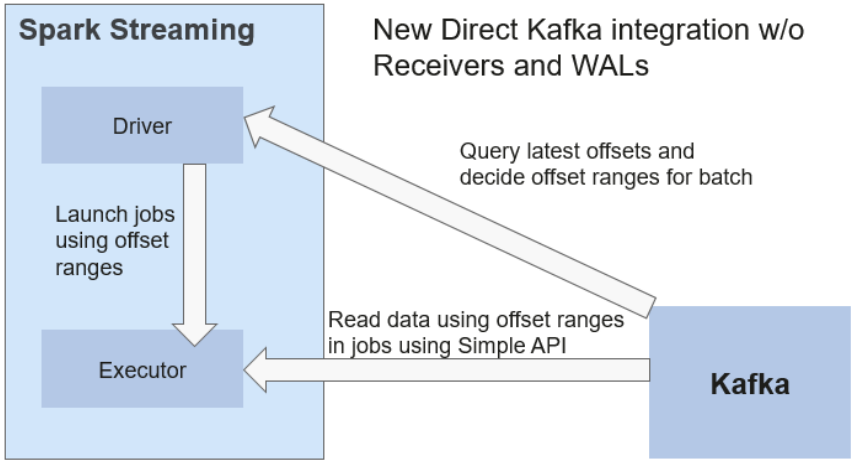
Spark Streaming Principle

Spark Streaming is a real-time computing framework built on the Spark, which expands the capability for processing massive streaming data. Spark supports two data processing approaches: Direct Streaming and Receiver.

Direct Streaming computing process

In Direct Streaming approach, Direct API is used to process data. Take Kafka Direct API as an example. Direct API provides offset location that each batch range will read from, which is much simpler than starting a receiver to continuously receive data from Kafka and written data to write-ahead logs (WALs). Then, each batch job is running and the corresponding offset data is ready in Kafka. These offset information can be securely stored in the checkpoint file and read by applications that failed to start.

Figure 1-93 Data transmission through Direct Kafka API



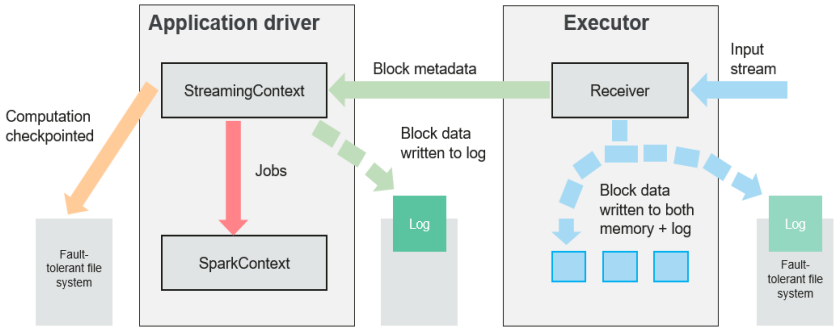
After the failure, Spark Streaming can read data from Kafka again and process the data segment. The processing result is the same no matter Spark Streaming fails or not, because the semantic is processed only once.

Direct API does not need to use the WAL and Receivers, and ensures that each Kafka record is received only once, which is more efficient. In this way, the Spark Streaming and Kafka can be well integrated, making streaming channels be featured with high fault-tolerance, high efficiency, and ease-of-use. Therefore, you are advised to use Direct Streaming to process data.

Receiver computing process

When a Spark Streaming application starts (that is, when the driver starts), the related StreamingContext (the basis of all streaming functions) uses SparkContext to start the receiver to become a long-term running task. These receivers receive and save streaming data to the Spark memory for processing. **Figure 1-94** shows the data transfer lifecycle.

Figure 1-94 Data transfer lifecycle



1. Receive data (blue arrow).

   Receiver divides a data stream into a series of blocks and stores them in the executor memory. In addition, after WAL is enabled, it writes data to the WAL of the fault-tolerant file system.

2. Notify the driver (green arrow).

   The metadata in the received block is sent to StreamingContext in the driver. The metadata includes:

   - Block reference ID used to locate the data position in the Executor memory.
   - Block data offset information in logs (if the WAL function is enabled).

3. Process data (red arrow).

   For each batch of data, StreamingContext uses block information to generate resilient distributed datasets (RDDs) and jobs. StreamingContext executes jobs by running tasks to process blocks in the executor memory.

4. Periodically set checkpoints (orange arrows).
5. For fault tolerance, StreamingContext periodically sets checkpoints and saves them to external file systems.

Fault Tolerance

Spark and its RDD allow seamless processing of failures of any Worker node in the cluster. Spark Streaming is built on top of Spark. Therefore, the Worker node of Spark Streaming also has the same fault tolerance capability. However, Spark Streaming needs to run properly in case of long-time running. Therefore, Spark must be able to recover from faults through the driver process (main process that coordinates all Workers). This poses challenges to the Spark driver fault-tolerance because the Spark driver may be any user application implemented in any computation mode. However, Spark Streaming has internal computation architecture. That is, it periodically executes the same Spark computation in each batch data. Such architecture allows it to periodically store checkpoints to reliable storage space and recover them upon the restart of Driver.

For source data such as files, the Driver recovery mechanism can ensure zero data loss because all data is stored in a fault-tolerant file system such as HDFS. However, for other data sources such as Kafka and Flume, some received data is cached only in memory and may be lost before being processed. This is caused by the distribution operation mode of Spark applications. When the driver process fails, all executors running in the Cluster Manager, together with all data in the memory, are terminated. To avoid such data loss, the WAL function is added to Spark Streaming.

WAL is often used in databases and file systems to ensure persistence of any data operation. That is, first record an operation to a persistent log and perform this operation on data. If the operation fails, the system is recovered by reading the log and re-applying the preset operation. The following describes how to use WAL to ensure persistence of received data:

Receiver is used to receive data from data sources such as Kafka. As a long-time running task in Executor, Receiver receives data, and also confirms received data if supported by data sources. Received data is stored in the Executor memory, and Driver delivers a task to Executor for processing.

After WAL is enabled, all received data is stored to log files in the fault-tolerant file system. Therefore, the received data does not lose even if Spark Streaming

fails. Besides, receiver checks correctness of received data only after the data is pre-written into logs. Data that is cached but not stored can be sent again by data sources after the driver restarts. These two mechanisms ensure zero data loss. That is, all data is recovered from logs or re-sent by data sources.

To enable the WAL function, perform the following operations:

- Set **streamingContext.checkpoint** (path-to-directory) to configure the checkpoint directory, which is an HDFS file path used to store streaming checkpoints and WALs.
- Set **spark.streaming.receiver.writeAheadLog.enable** of SparkConf to **true** (the default value is **false**).

After WAL is enabled, all receivers have the advantage of recovering from reliable received data. You are advised to disable the multi-replica mechanism because the fault-tolerant file system of WAL may also replicate the data.

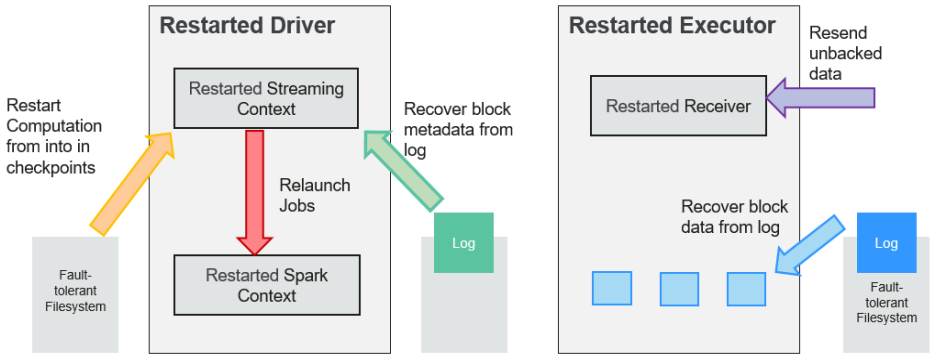
NOTE

The data receiving throughput is lowered after WAL is enabled. All data is written into the fault-tolerant file system. As a result, the write throughput of the file system and the network bandwidth for data replication may become the potential bottleneck. To solve this problem, you are advised to create more receivers to increase the degree of data receiving parallelism or use better hardware to improve the throughput of the fault-tolerant file system.

Recovery Process

When a failed driver is restarted, restart it as follows:

Figure 1-95 Computing recovery process



1. Recover computing. (Orange arrow)

   Use checkpoint information to restart Driver, reconstruct SparkContext and restart Receiver.

2. Recover metadata block. (Green arrow)

   This operation ensures that all necessary metadata blocks are recovered to continue the subsequent computing recovery.

3. Relaunch unfinished jobs. (Red arrow)

   Recovered metadata is used to generate RDDs and corresponding jobs for interrupted batch processing due to failures.

4. Read block data saved in logs. (Blue arrow)

Block data is directly read from WALs during execution of the preceding jobs, and therefore all essential data reliably stored in logs is recovered.

5. Resend unconfirmed data. (Purple arrow)

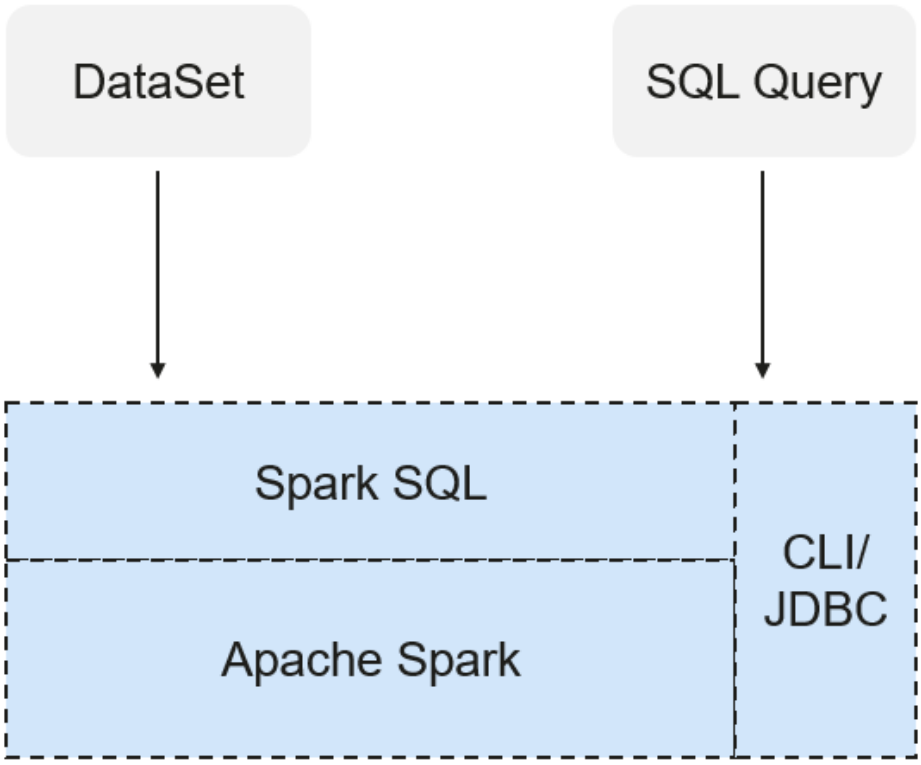
   Data that is cached but not stored to logs upon failures is re-sent by data sources, because the receiver does not confirm the data.

Therefore, by using WALs and reliable Receiver, Spark Streaming can avoid input data loss caused by Driver failures.

SparkSQL and DataSet Principle

SparkSQL

Figure 1-96 SparkSQL and DataSet



Spark SQL is a module for processing structured data. In Spark application, SQL statements or DataSet APIs can be seamlessly used for querying structured data.

Spark SQL and DataSet also provide a universal method for accessing multiple data sources such as Hive, CSV, Parquet, ORC, JSON, and JDBC. These data sources also allow data interaction. Spark SQL reuses the Hive frontend processing logic and metadata processing module. With the Spark SQL, you can directly query existing Hive data.

In addition, Spark SQL also provides API, CLI, and JDBC APIs, allowing diverse accesses to the client.

Spark SQL Native DDL/DML

In Spark 1.5, lots of Data Definition Language (DDL)/Data Manipulation Language (DML) commands are pushed down to and run on the Hive, causing coupling with the Hive and inflexibility such as unexpected error reports and results.

Spark realizes command localization and replaces the Hive with Spark SQL Native DDL/DML to run DDL/DML commands. Additionally, the decoupling from the Hive is realized and commands can be customized.

DataSet

A DataSet is a strongly typed collection of domain-specific objects that can be transformed in parallel using functional or relational operations. Each Dataset also has an untyped view called a DataFrame, which is a Dataset of Row.

The DataFrame is a structured and distributed dataset consisting of multiple columns. The DataFrame is equal to a table in the relationship database or the DataFrame in the R/Python. The DataFrame is the most basic concept in the Spark SQL, which can be created by using multiple methods, such as the structured dataset, Hive table, external database or RDD.

Operations available on DataSets are divided into transformations and actions.

- A transformation operation can generate a new DataSet,
  for example, **map**, **filter**, **select**, and **aggregate (groupBy)**.
- An action operation can trigger computation and return results,
  for example, **count**, **show**, or write data to the file system.

You can use either of the following methods to create a DataSet:

- The most common way is by pointing Spark to some files on storage systems, using the **read** function available on a SparkSession.
  ```
  val people = spark.read.parquet("...").as[Person]  // Scala
  DataSet<Person> people = spark.read().parquet("...").as(Encoders.bean(Person.class));//Java
  ```
- You can also create a DataSet using the transformation operation available on an existing one. For example, apply the map operation on an existing DataSet to create a DataSet:
  ```
  val names = people.map(_.name) // In Scala: names is Dataset.
  Dataset<String> names = people.map((Person p) -> p.name, Encoders.STRING)); // Java
  ```

CLI and JDBCServer

In addition to programming APIs, Spark SQL also provides the CLI/JDBC APIs.

- Both **spark-shell** and **spark-sql** scripts can provide the CLI for debugging.
- JDBCServer provides JDBC APIs. External systems can directly send JDBC requests to calculate and parse structured data.

SparkSession Principle

SparkSession is a unified API in Spark and can be regarded as a unified entry for reading data. SparkSession provides a single entry point to perform many operations that were previously scattered across multiple classes, and also provides accessor methods to these older classes to maximize compatibility.

A SparkSession can be created using a builder pattern. The builder will automatically reuse the existing SparkSession if there is a SparkSession; or create a SparkSession if it does not exist. During I/O transactions, the configuration item settings in the builder are automatically synchronized to Spark and Hadoop.

```
import org.apache.spark.sql.SparkSession
val sparkSession = SparkSession.builder
  .master("local")
  .appName("my-spark-app")
  .config("spark.some.config.option", "config-value")
  .getOrCreate()
```

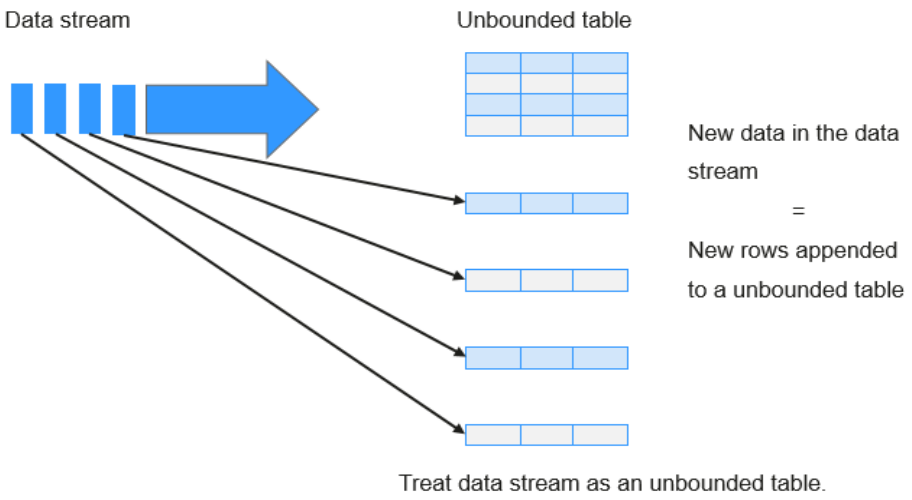
- SparkSession can be used to execute SQL queries on data and return results as DataFrame.
  ```
  sparkSession.sql("select * from person").show
  ```
- SparkSession can be used to set configuration items during running. These configuration items can be replaced with variables in SQL statements.
  ```
  sparkSession.conf.set("spark.some.config", "abcd")
  sparkSession.conf.get("spark.some.config")
  sparkSession.sql("select ${spark.some.config}")
  ```
- SparkSession also includes a "catalog" method that contains methods to work with Metastore (data catalog). After this method is used, a dataset is returned, which can be run using the same Dataset API.
  ```
  val tables = sparkSession.catalog.listTables()
  val columns = sparkSession.catalog.listColumns("myTable")
  ```
- Underlying SparkContext can be accessed by SparkContext API of SparkSession.
  ```
  val sparkContext = sparkSession.sparkContext
  ```

Structured Streaming Principle

Structured Streaming is a stream processing engine built on the Spark SQL engine. You can use the Dataset/DataFrame API in Scala, Java, Python, or R to express streaming aggregations, event-time windows, and stream-stream joins. If streaming data is incrementally and continuously produced, Spark SQL will continue to process the data and synchronize the result to the result set. In addition, the system ensures end-to-end exactly-once fault-tolerance guarantees through checkpoints and WALs.

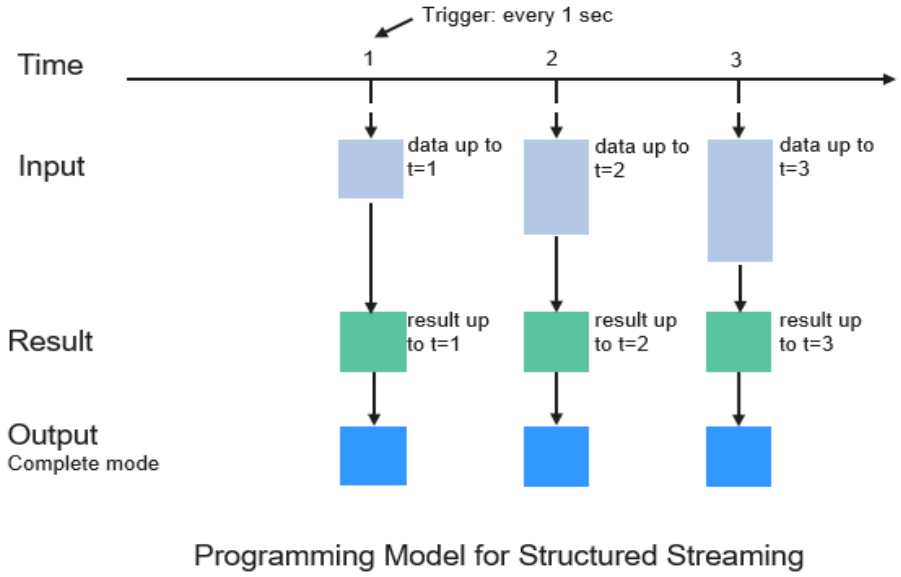
The core of Structured Streaming is to take streaming data as an incremental database table. Similar to the data block processing model, the streaming data processing model applies query operations on a static database table to streaming computing, and Spark uses standard SQL statements for query, to obtain data from the incremental and unbounded table.

Figure 1-97 Unbounded table of Structured Streaming



Each query operation will generate a result table. At each trigger interval, updated data will be synchronized to the result table. Whenever the result table is updated, the updated result will be written into an external storage system.

Figure 1-98 Structured Streaming data processing model



Programming Model for Structured Streaming

Storage modes of Structured Streaming at the output phase are as follows:

- Complete Mode: The updated result sets are written into the external storage system. The write operation is performed by a connector of the external storage system.
- Append Mode: If an interval is triggered, only added data in the result table will be written into an external system. This is applicable only on the queries where existing rows in the result table are not expected to change.

- Update Mode: If an interval is triggered, only updated data in the result table will be written into an external system, which is the difference between the Complete Mode and Update Mode.

Concepts

- **RDD**

  Resilient Distributed Dataset (RDD) is a core concept of Spark. It indicates a read-only and partitioned distributed dataset. Partial or all data of this dataset can be cached in the memory and reused between computations.

  RDD Creation

  – An RDD can be created from the input of HDFS or other storage systems that are compatible with Hadoop.
  – A new RDD can be converted from a parent RDD.
  – An RDD can be converted from a collection of datasets through encoding.

  RDD Storage

  – You can select different storage levels to store an RDD for reuse. (There are 11 storage levels to store an RDD.)
  – By default, the RDD is stored in the memory. When the memory is insufficient, the RDD overflows to the disk.

- **RDD Dependency**

  The RDD dependency includes the narrow dependency and wide dependency.

  Figure 1-99 RDD dependency

  – **Narrow dependency**: Each partition of the parent RDD is used by at most one partition of the child RDD.
  – **Wide dependency**: Partitions of the child RDD depend on all partitions of the parent RDD.

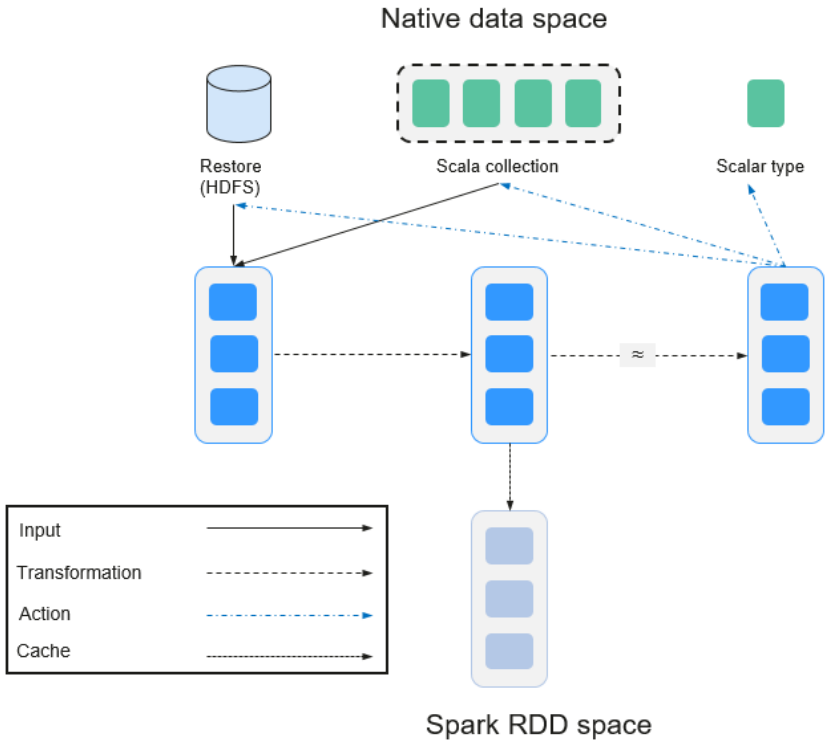
  The narrow dependency facilitates the optimization. Logically, each RDD operator is a fork/join (the join is not the join operator mentioned above but the barrier used to synchronize multiple concurrent tasks); fork the RDD to

each partition, and then perform the computation. After the computation, join the results, and then perform the fork/join operation on the next RDD operator. It is uneconomical to directly translate the RDD into physical implementation. The first is that every RDD (even intermediate result) needs to be physicalized into memory or storage, which is time-consuming and occupies much space. The second is that as a global barrier, the join operation is very expensive and the entire join process will be slowed down by the slowest node. If the partitions of the child RDD narrowly depend on that of the parent RDD, the two fork/join processes can be combined to implement classic fusion optimization. If the relationship in the continuous operator sequence is narrow dependency, multiple fork/join processes can be combined to reduce a large number of global barriers and eliminate the physicalization of many RDD intermediate results, which greatly improves the performance. This is called pipeline optimization in Spark.

- **Transformation and Action (RDD Operations)**

  Operations on RDD include transformation (the return value is an RDD) and action (the return value is not an RDD). **Figure 1-100** shows the RDD operation process. The transformation is lazy, which indicates that the transformation from one RDD to another RDD is not immediately executed. Spark only records the transformation but does not execute it immediately. The real computation is started only when the action is started. The action returns results or writes the RDD data into the storage system. The action is the driving force for Spark to start the computation.

  Figure 1-100 RDD operation



The data and operation model of RDD are quite different from those of Scala.

```
val file = sc.textFile("hdfs://...")
val errors = file.filter(_.contains("ERROR"))
```

```
errors.cache()
errors.count()
```

a. The textFile operator reads log files from the HDFS and returns files (as an RDD).
b. The filter operator filters rows with **ERROR** and assigns them to errors (a new RDD). The filter operator is a transformation.
c. The cache operator caches errors for future use.
d. The count operator returns the number of rows of errors. The count operator is an action.

Transformation includes the following types:

- The RDD elements are regarded as simple elements.

  The input and output has the one-to-one relationship, and the partition structure of the result RDD remains unchanged, for example, map.

  The input and output has the one-to-many relationship, and the partition structure of the result RDD remains unchanged, for example, flatMap (one element becomes a sequence containing multiple elements after map and then flattens to multiple elements).

  The input and output has the one-to-one relationship, but the partition structure of the result RDD changes, for example, union (two RDDs integrates to one RDD, and the number of partitions becomes the sum of the number of partitions of two RDDs) and coalesce (partitions are reduced).

  Operators of some elements are selected from the input, such as filter, distinct (duplicate elements are deleted), subtract (elements only exist in this RDD are retained), and sample (samples are taken).
- The RDD elements are regarded as key-value pairs.

  Perform the one-to-one calculation on the single RDD, such as mapValues (the partition mode of the source RDD is retained, which is different from map).

  Sort the single RDD, such as sort and partitionBy (partitioning with consistency, which is important to the local optimization).

  Restructure and reduce the single RDD based on key, such as groupByKey and reduceByKey.

  Join and restructure two RDDs based on the key, such as join and cogroup.

  NOTE

  The later three operations involving sorting are called shuffle operations.

Action includes the following types:

- Generate scalar configuration items, such as **count** (the number of elements in the returned RDD), **reduce**, **fold/aggregate** (the number of scalar configuration items that are returned), and **take** (the number of elements before the return).
- Generate the Scala collection, such as **collect** (import all elements in the RDD to the Scala collection) and **lookup** (look up all values corresponds to the key).
- Write data to the storage, such as **saveAsTextFile** (which corresponds to the preceding **textFile**).

  - Check points, such as the **checkpoint** operator. When Lineage is quite long (which occurs frequently in graphics computation), it takes a long period of time to execute the whole sequence again when a fault occurs. In this case, checkpoint is used as the check point to write the current data to stable storage.

- **Shuffle**

  Shuffle is a specific phase in the MapReduce framework, which is located between the Map phase and the Reduce phase. If the output results of Map are to be used by Reduce, the output results must be hashed based on a key and distributed to each Reducer. This process is called Shuffle. Shuffle involves the read and write of the disk and the transmission of the network, so that the performance of Shuffle directly affects the operation efficiency of the entire program.

  The figure below shows the entire process of the MapReduce algorithm.

  Figure 1-101 Algorithm process

  Shuffle is a bridge to connect data. The following describes the implementation of shuffle in Spark.

  Shuffle divides a job of Spark into multiple stages. The former stages contain one or more ShuffleMapTasks, and the last stage contains one or more ResultTasks.

- **Spark Application Structure**

  The Spark application structure includes the initialized SparkContext and the main program.

  - Initialized SparkContext: constructs the operating environment of the Spark Application.

    Constructs the SparkContext object. The following is an example:

    ```
    new SparkContext(master, appName, [SparkHome], [jars])
    ```

    Parameter description:

    master: indicates the link string. The link modes include local, Yarn-cluster, and Yarn-client.

    appName: indicates the application name.

    SparkHome: indicates the directory where Spark is installed in the cluster.

    jars: indicates the code and dependency package of an application.

  - Main program: processes data.

- **Spark Shell Commands**

  The basic Spark shell commands support the submission of Spark applications. The Spark shell commands are as follows:

  ```
  ./bin/spark-submit \
    --class <main-class> \
    --master <master-url> \
    ... # other options
    <application-jar> \
    [application-arguments]
  ```

  Parameter description:

  --class: indicates the name of the class of a Spark application.

  --master: indicates the master to which the Spark application links, such as Yarn-client and Yarn-cluster.

  application-jar: indicates the path of the JAR file of the Spark application.

  application-arguments: indicates the parameter required to submit the Spark application. This parameter can be left blank.

- **Spark JobHistory Server**

  The Spark web UI is used to monitor the details in each phase of the Spark framework of a running or historical Spark job and provide the log display, which helps users to develop, configure, and optimize the job in more fine-grained units.

1.3.24.2 Spark HA Solution

1.3.24.2.1 Spark Multi-active Instance

Background

Based on existing JDBCServers in the community, multi-active-instance HA is used to achieve the high availability. In this mode, multiple JDBCServers coexist in the cluster and the client can randomly connect any JDBCServer to perform service operations. When one or multiple JDBCServers stop working, a client can connect to another normal JDBCServer.

Compared with active/standby HA, multi-active instance HA eliminates the following restrictions:

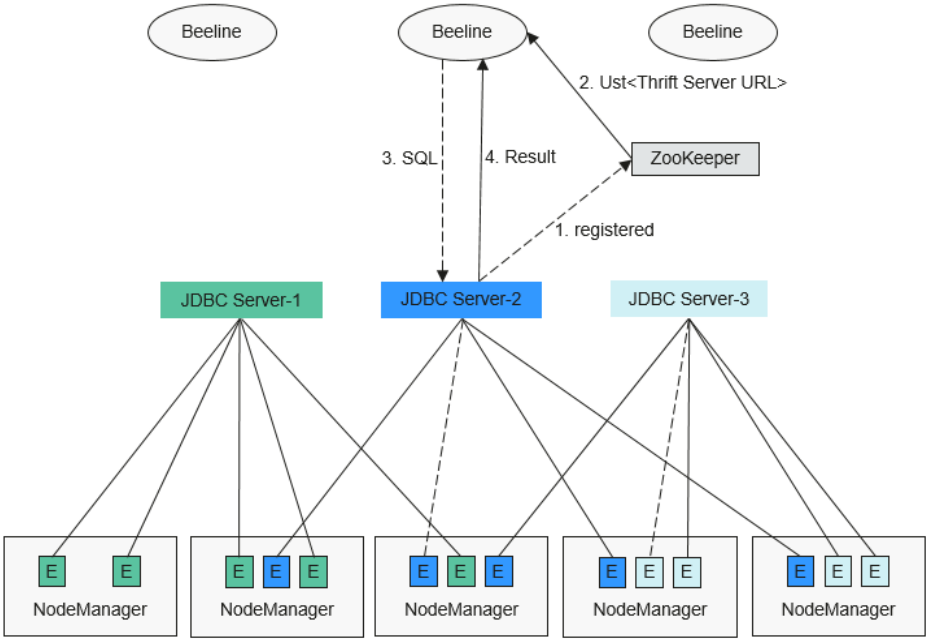
- In active/standby HA, when the active/standby switchover occurs, the unavailable period cannot be controlled by JDBCServer, but determined by Yarn service resources.
- In Spark, the Thrift JDBC similar to HiveServer2 provides services and users access services through Beeline and JDBC API. Therefore, the processing capability of the JDBCServer cluster depends on the single-point capability of the primary server, and the scalability is insufficient.

Multi-active instance HA not only prevents service interruption caused by switchover, but also enables cluster scale-out to secure high concurrency.

Implementation

The following figure shows the basic principle of multi-active instance HA of Spark JDBCServer.

Figure 1-102 Spark JDBCServer HA



1. After JDBCServer is started, it registers with ZooKeeper by writing node information in a specified directory. Node information includes the JDBCServer instance IP, port number, version, and serial number (information of different nodes is separated by commas).

   An example is provided as follows:

   ```
   [serverUri=192.168.169.84:22550
   ;version=xxx;sequence=0000001244,serverUri=192.168.195.232:22550 ;version=xxx;sequence=0000001242,serverUri=192.168.81.37:22550 ;version=xxx;sequence=0000001243]
   ```

2. To connect to JDBCServer, the client must specify the namespace, which is the directory of JDBCServer instances in ZooKeeper. During the connection, a JDBCServer instance is randomly selected from the specified namespace. For details about URL, see **URL Connection**.
3. After the connection succeeds, the client sends SQL statements to JDBCServer.
4. JDBCServer executes received SQL statements and sends results back to the client.

In multi-active instance HA mode, all JDBCServer instances are independent and equivalent. When one instance is interrupted during upgrade, other JDBCServer instances can accept the connection request from the client.

Following rules must be followed in the multi-active instance HA of Spark JDBCServer:

- If a JDBCServer instance exits abnormally, no other instance will take over the sessions and services running on this abnormal instance.
- When the JDBCServer process is stopped, corresponding nodes are deleted from ZooKeeper.
- The client randomly selects the server, which may result in uneven session allocation, and finally result in imbalance of instance load.

- After the instance enters the maintenance mode (in which no new connection request from the client is accepted), services still running on the instance may fail when the decommissioning times out.

URL Connection

Multi-active instance mode

In multi-active instance mode, the client reads content from the ZooKeeper node and connects to JDBCServer. The connection strings are as follows:

- Security mode:
  - If Kinit authentication is enabled, the JDBCURL is as follows:
    jdbc:hive2:// *<zkNode1_IP>:<zkNode1_Port>,<zkNode2_IP>:<zkNode2_Port>,<zkNode3_IP>:<zkNode3_Port>*/;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=sparkthriftserver;saslQop=auth-conf;auth=KERBEROS;principal=spark/hadoop.*<System domain name>*@*<System domain name>*;

    NOTE

    - **<zkNode_IP>:<zkNode_Port>** indicates the ZooKeeper URL. Use commas (,) to separate multiple URLs,

      For example,
      192.168.81.37:2181,192.168.195.232:2181,192.168.169.84:2181.
    - **sparkthriftserver** indicates the directory in ZooKeeper, where a random JDBCServer instance is connected to the client.

    For example, when you use Beeline client for connection in security mode, run the following command:

    sh *CLIENT_HOME*/**spark/bin/beeline -u "jdbc:hive2://** *<zkNode1_IP>:<zkNode1_Port>,<zkNode2_IP>:<zkNode2_Port>,<zkNode3_IP>:<zkNode3_Port>*/;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=sparkthriftserver;saslQop=auth-conf;auth=KERBEROS;principal=spark/hadoop.*<System domain name>*@*<System domain name>*;"
  - If Keytab authentication is enabled, the JDBCURL is as follows:
    jdbc:hive2://*<zkNode1_IP>:<zkNode1_Port>,<zkNode2_IP>:<zkNode2_Port>,<zkNode3_IP>:<zkNode3_Port>*/;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=sparkthriftserver;saslQop=auth-conf;auth=KERBEROS;principal=spark/hadoop.*<System domain name>*@*<System domain name>*;user.principal=*<principal_name>*;user.keytab=*<path_to_keytab>*

    <principal_name> indicates the principal of Kerberos user, for example, **test@***<System domain name>*. *<path_to_keytab>* indicates the Keytab file path corresponding to *<principal_name>*, for example, **/opt/auth/test/user.keytab**.
- Common mode:
  jdbc:hive2://*<zkNode1_IP>:<zkNode1_Port>,<zkNode2_IP>:<zkNode2_Port>,<zkNode3_IP>:<zkNode3_Port>*|;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=**sparkthriftserver**;

  For example, when you use Beeline client for connection in common mode, run the following command:

  sh *CLIENT_HOME*/**spark/bin/beeline -u "jdbc:hive2://** *<zkNode1_IP>:<zkNode1_Port>,<zkNode2_IP>:<zkNode2_Port>,<zkNode3_IP>:<zkNode3_Port>*/;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=sparkthriftserver;"

Non-multi-active instance mode

In non-multi-active instance mode, a client connects to a specified JDBCServer node. Compared with multi-active instance mode, the connection string in non-multi-active instance mode does not contain **serviceDiscoveryMode** and **zooKeeperNamespace** parameters about ZooKeeper.

For example, when you use Beeline client to connect JDBCServer in non-multi-active instance mode, run the following command:

sh *CLIENT_HOME*/**spark/bin/beeline -u "jdbc:hive2://**<*server_IP*>:<*server_Port*>**/;user.principal=spark/hadoop.**<*System domain name*>**@**<*System domain name*>**;saslQop=auth-conf;auth=KERBEROS;principal=spark/hadoop.**<*System domain name*>**@**<*System domain name*>**;"**

NOTE

- **<server_IP>:<server_Port>** indicates the URL of the specified JDBCServer node.
- **CLIENT_HOME** indicates the client path.

Except the connection method, operations of JDBCServer API in multi-active instance mode and non-multi-active instance mode are the same.

1.3.24.2.2 Spark Multi-tenant

Background

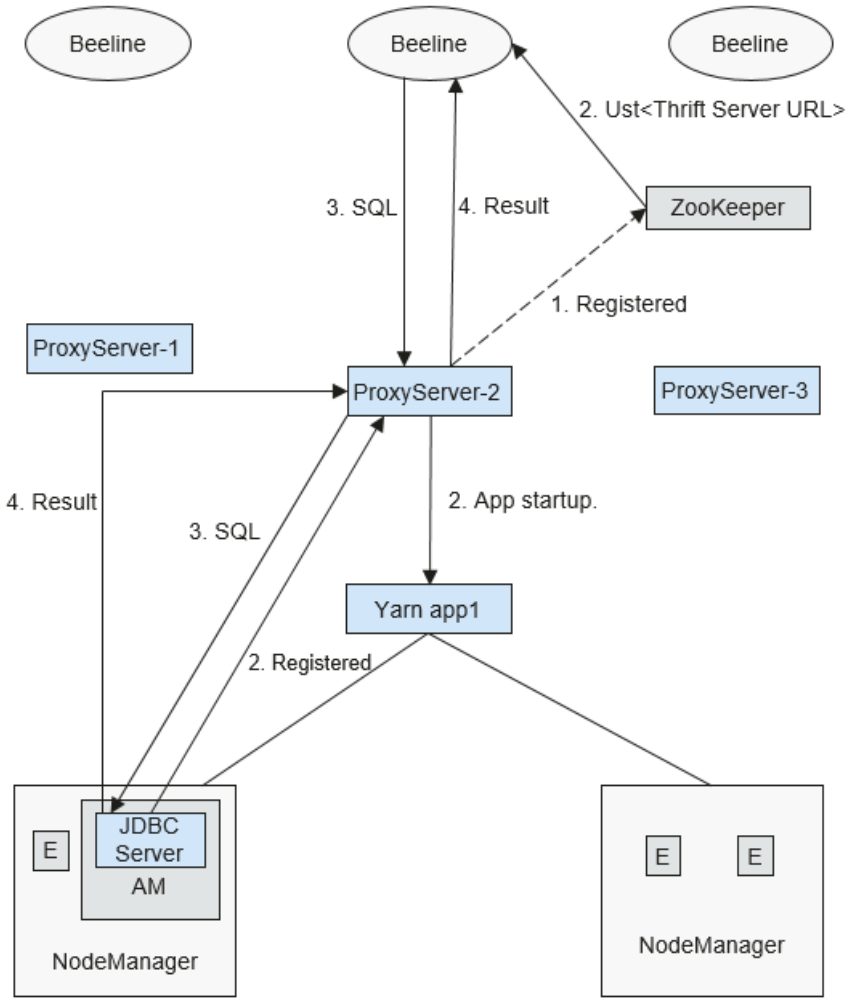
In the JDBCServer multi-active instance mode, JDBCServer implements the Yarn-client mode but only one Yarn resource queue is available. To solve the resource limitation problem, the multi-tenant mode is introduced.

In multi-tenant mode, JDBCServers are bound with tenants. Each tenant corresponds to one or more JDBCServers, and a JDBCServer provides services for only one tenant. Different tenants can be configured with different Yarn queues to implement resource isolation. In addition, JDBCServer can be dynamically started as required to avoid resource waste.

Implementation

Figure 1-103 shows the HA solution of the multi-tenant mode.

Figure 1-103 Multi-tenant mode of Spark JDBCServer



1. When ProxyServer is started, it registers with ZooKeeper by writing node information in a specified directory. Node information includes the instance IP, port number, version, and serial number (information of different nodes is separated by commas).

   NOTE

   In multi-tenant mode, the JDBCServer instance on MRS page indicates ProxyServer, the JDBCServer agent.

   An example is provided as follows:

   ```
   serverUri=192.168.169.84:22550
   ;version=xxx;sequence=0000001244,serverUri=192.168.195.232:22550
   ;version=xxx;sequence=0000001242,serverUri=192.168.81.37:22550
   ;version=xxx;sequence=0000001243,
   ```

2. To connect to ProxyServer, the client must specify a namespace, which is the directory of the ProxyServer instance that you want to access in ZooKeeper. When the client connects to ProxyServer, an instance under Namespace is randomly selected for connection. For details about the URL, see **URL Connection**.
3. After the client successfully connects to ProxyServer, ProxyServer checks whether the JDBCServer of a tenant exists. If yes, Beeline connects the

JDBCServer. If no, a new JDBCServer is started in Yarn-cluster mode. After the startup of JDBCServer, ProxyServer obtains the IP address of the JDBCServer and establishes the connection between Beeline and JDBCServer.

4. The client sends SQL statements to ProxyServer, which then forwards statements to the connected JDBCServer. JDBCServer returns the results to ProxyServer, which then returns the results to the client.

In multi-tenant HA mode, all ProxyServer instances are independent and equivalent. If one instance is interrupted during upgrade, other instances can accept the connection request from the client.

URL Connection

Multi-tenant mode

In multi-tenant mode, the client reads content from the ZooKeeper node and connects to ProxyServer. The connection strings are as follows:

- Security mode:
  - If Kinit authentication is enabled, the client URL is as follows:
    jdbc:hive2://<*zkNode1_IP*>**:**<*zkNode1_Port*>**,**<*zkNode2_IP*>**:**<*zkNode2_Port*>**,**<*zkNode3_IP*>**:**<*zkNode3_Port*>**/;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=sparkthriftserver;saslQop=auth-conf;auth=KERBEROS;principal=spark/hadoop.**<*System domain name*>**@**<*System domain name*>**;**

    NOTE

    - **<zkNode_IP>:<zkNode_Port>** indicates the ZooKeeper URL. Use commas (,) to separate multiple URLs,

      For example, **192.168.81.37:2181,192.168.195.232:2181,192.168.169.84:2181**.
    - **sparkthriftserver** indicates the ZooKeeper directory, where a random JDBCServer instance is connected to the client.

    For example, when you use Beeline client for connection in security mode, run the following command:

    sh *CLIENT_HOME*/**spark/bin/beeline -u "jdbc:hive2://**<*zkNode1_IP*>**:**<*zkNode1_Port*>**,**<*zkNode2_IP*>**:**<*zkNode2_Port*>**,**<*zkNode3_IP*>**:**<*zkNode3_Port*>**/;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=sparkthriftserver;saslQop=auth-conf;auth=KERBEROS;principal=spark/hadoop.**<*System domain name*>**@**<*System domain name*>**;"**
  - If Keytab authentication is enabled, the URL is as follows:
    jdbc:hive2://<*zkNode1_IP*>**:**<*zkNode1_Port*>**,**<*zkNode2_IP*>**:**<*zkNode2_Port*>**,**<*zkNode3_IP*>**:**<*zkNode3_Port*>**/;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=sparkthriftserver;saslQop=auth-conf;auth=KERBEROS;principal=spark/hadoop.**<*System domain name*>**@**<*System domain name*>**;user.principal=**<*principal_name*>**;user.keytab=**<*path_to_keytab*>

    <*principal_name*> indicates the principal of Kerberos user, for example, **test@**<*System domain name*>. <*path_to_keytab*> indicates the Keytab file path corresponding to <*principal_name*>, for example, **/opt/auth/test/user.keytab**.
- Common mode:
  jdbc:hive2://<*zkNode1_IP*>**:**<*zkNode1_Port*>**,**<*zkNode2_IP*>**:**<*zkNode2_Port*>**,**<*zkNode3_IP*>**:**<*zkNode3_Port*>**/**;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=**sparkthriftserver**;

For example, when you use Beeline client for connection in common mode, run the following command:

sh *CLIENT_HOME*/**spark/bin/beeline -u "jdbc:hive2://***<zkNode1_IP>:<zkNode1_Port>,<zkNode2_IP>:<zkNode2_Port>,<zkNode3_IP>:<zkNode3_Port>*/**;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=sparkthriftserver;"**

Non-multi-tenant mode

In non-multi-tenant mode, a client connects to a specified JDBCServer node. Compared with multi-active instance mode, the connection string in non-multi-active instance mode does not contain **serviceDiscoveryMode** and **zooKeeperNamespace** parameters about ZooKeeper.

For example, when you use Beeline client to connect JDBCServer in non-multi-tenant instance mode, run the following command:

sh *CLIENT_HOME*/**spark/bin/beeline -u "jdbc:hive2://***<server_IP>:<server_Port>*/**;user.principal=spark/hadoop.***<System domain name>@<System domain name>***;saslQop=auth-conf;auth=KERBEROS;principal=spark/hadoop.***<System domain name>@<System domain name>***;"**

NOTE

- **<server_IP>:<server_Port>** indicates the URL of the specified JDBCServer node.
- **CLIENT_HOME** indicates the client path.

Except the connection method, other operations of JDBCServer API in multi-tenant mode and non-multi-tenant mode are the same.

Specifying a Tenant

Generally, the client submitted by a user connects to the default JDBCServer of the tenant to which the user belongs. If you want to connect the client to the JDBCServer of a specified tenant, add the **--hiveconf mapreduce.job.queuename** parameter.

Command for connecting Beeline is as follows (**aaa** indicates the tenant name):

beeline --hiveconf mapreduce.job.queuename=aaa -u 'jdbc:hive2://192.168.39.30:2181,192.168.40.210:2181,192.168.215.97:2181;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=sparkthriftserver;saslQop=auth-conf;auth=KERBEROS;principal=spark/hadoop.*<System domain name>@<System domain name>*;'

1.3.24.3 Relationship Between Spark and Other Components

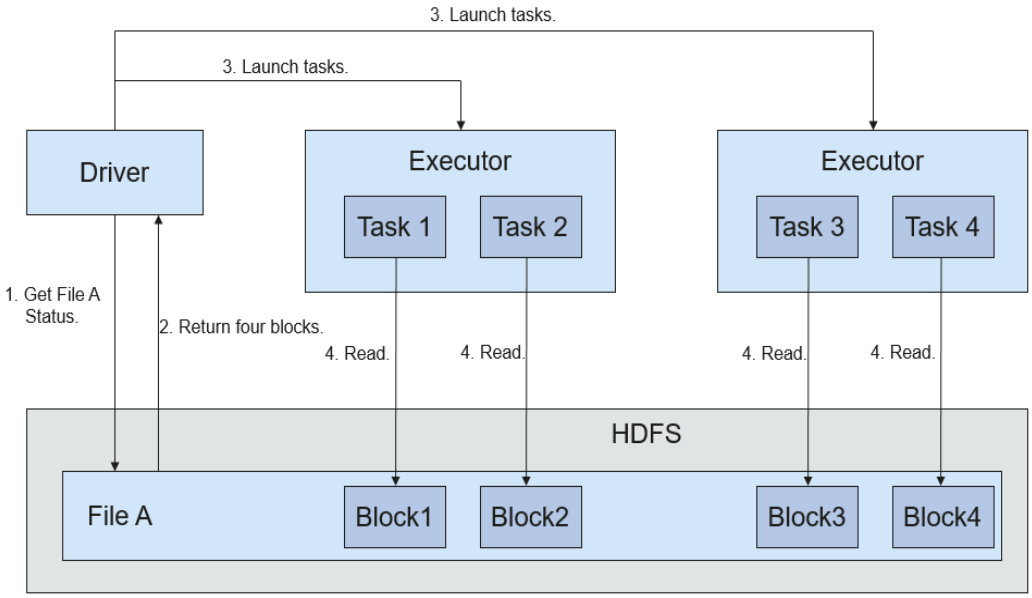
Relationship Between Spark and HDFS

Data computed by Spark comes from multiple data sources, such as local files and HDFS. Most data comes from HDFS which can read data in large scale for parallel computing After being computed, data can be stored in HDFS.

Spark involves Driver and Executor. Driver schedules tasks and Executor runs tasks.

Figure 1-104 describes the file reading process.

Figure 1-104 File reading process

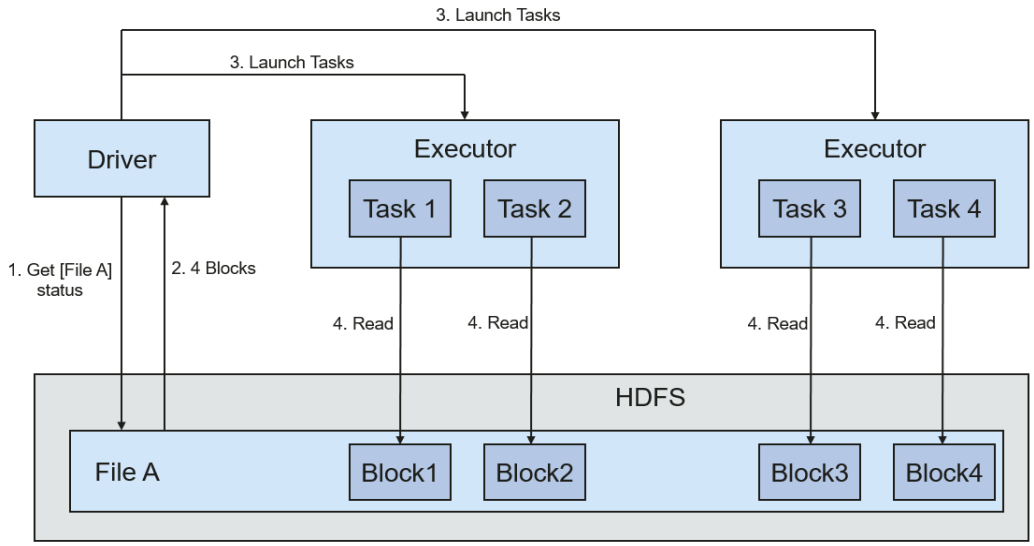


The file reading process is as follows:

1. Driver interconnects with HDFS to obtain the information of File A.
2. The HDFS returns the detailed block information about this file.
3. Driver sets a parallel degree based on the block data amount, and creates multiple tasks to read the blocks of this file.
4. Executor runs the tasks and reads the detailed blocks as part of the Resilient Distributed Dataset (RDD).

Figure 1-105 describes the file writing process.

Figure 1-105 File writing process



The file writing process is as follows:

1. Driver creates a directory where the file is to be written.
2. Based on the RDD distribution status, the number of tasks related to data writing is computed, and these tasks are sent to Executor.
3. Executor runs these tasks, and writes the RDD data to the directory created in 1.

Relationship with Yarn

The Spark computing and scheduling can be implemented using Yarn mode. Spark enjoys the computing resources provided by Yarn clusters and runs tasks in a distributed way. Spark on Yarn has two modes: Yarn-cluster and Yarn-client.

- Yarn-cluster mode

  Figure 1-106 describes the operation framework.

  Figure 1-106 Spark on Yarn-cluster operation framework

  Spark on Yarn-cluster implementation process:

  a. The client generates the application information, and then sends the information to ResourceManager.
  b. ResourceManager allocates the first container (ApplicationMaster) to SparkApplication and starts the driver on the container.
  c. ApplicationMaster applies for resources from ResourceManager to run the container.

     ResourceManager allocates the containers to ApplicationMaster, which communicates with the related NodeManagers and starts the executor in the obtained container. After the executor is started, it registers with drivers and applies for tasks.

d. Drivers allocate tasks to the executors.

e. Executors run tasks and report the operating status to Drivers.

- Yarn-client mode

  Figure 1-107 describes the operation framework.

  Figure 1-107 Spark on Yarn-client operation framework

  Spark on Yarn-client implementation process:

  NOTE

  In Yarn-client mode, the Driver is deployed and started on the client. In Yarn-client mode, the client of an earlier version is incompatible. The Yarn-cluster mode is recommended.

  a. The client sends the Spark application request to ResourceManager, and packages all information required to start ApplicationMaster and sends the information to ResourceManager. ResourceManager then returns the results to the client. The results include information such as ApplicationId, and the upper limit as well as lower limit of available resources. After receiving the request, ResourceManager finds a proper node for ApplicationMaster and starts it on this node. ApplicationMaster is a role in Yarn, and the process name in Spark is ExecutorLauncher.

  b. Based on the resource requirements of each task, ApplicationMaster can apply for a series of containers to run tasks from ResourceManager.

  c. After receiving the newly allocated container list (from ResourceManager), ApplicationMaster sends information to the related NodeManagers to start the containers.

     ResourceManager allocates the containers to ApplicationMaster, which communicates with the related NodeManagers and starts the executor in the obtained container. After the executor is started, it registers with drivers and applies for tasks.

NOTE

Running Containers will not be suspended to release resources.

d. Drivers allocate tasks to the executors. Executors run tasks and report the operating status to Drivers.

1.3.24.4 Spark Open Source New Features

Purpose

Compared with Spark 1.5, Spark3x has some new open-source features. The specific features or concepts are as follows:

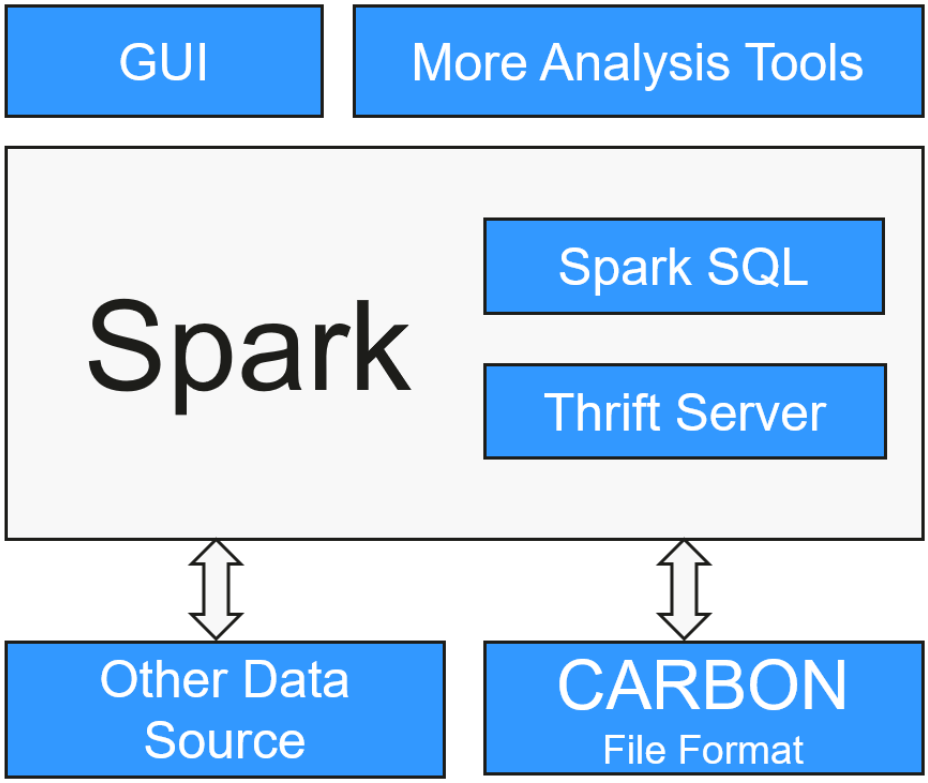
- DataSet: For details, see **SparkSQL and DataSet Principle**.
- Spark SQL Native DDL/DML: For details, see **SparkSQL and DataSet Principle**.
- SparkSession: For details, see **SparkSession Principle**.
- Structured Streaming: For details, see **Structured Streaming Principle**.
- Optimizing Small Files
- Optimizing the Aggregate Algorithm
- Optimizing Datasource Tables
- Merging CBO

1.3.24.5 Spark Enhanced Open Source Features

1.3.24.5.1 CarbonData Overview

CarbonData is a new Apache Hadoop native data-store format. CarbonData allows faster interactive queries over PetaBytes of data using advanced columnar storage, index, compression, and encoding techniques to improve computing efficiency. In addition, CarbonData is also a high-performance analysis engine that integrates data sources with Spark.

Figure 1-108 Basic architecture of CarbonData



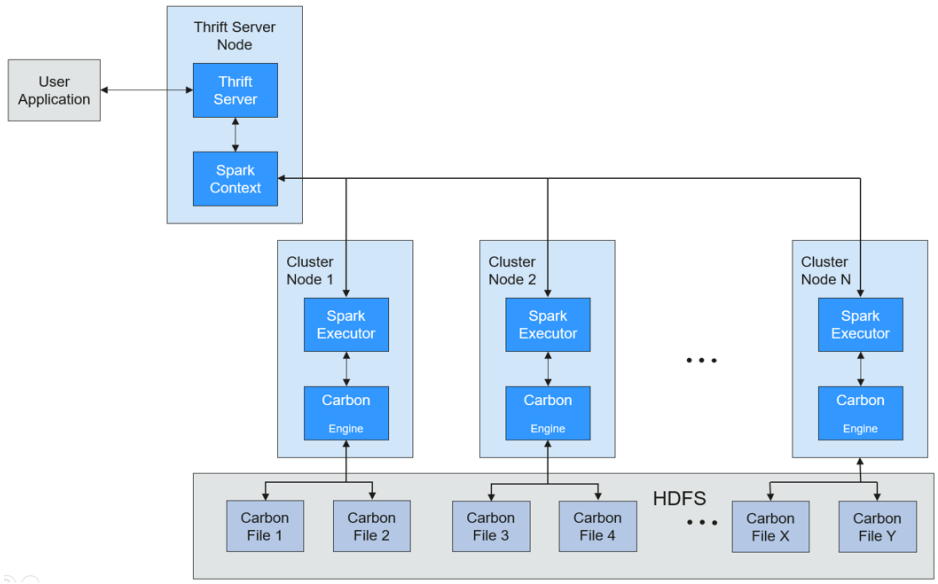
The purpose of using CarbonData is to provide quick response to ad hoc queries of big data. Essentially, CarbonData is an Online Analytical Processing (OLAP) engine, which stores data by using tables similar to those in Relational Database Management System (RDBMS). You can import more than 10 TB data to tables created in CarbonData format, and CarbonData automatically organizes and stores data using the compressed multi-dimensional indexes. After data is loaded to CarbonData, CarbonData responds to ad hoc queries in seconds.

CarbonData integrates data sources into the Spark ecosystem and you can query and analyze the data using Spark SQL. You can also use the third-party tool JDBCServer provided by Spark to connect to SparkSQL.

Topology of CarbonData

CarbonData runs as a data source inside Spark. Therefore, CarbonData does not start any additional processes on nodes in clusters. CarbonData engine runs inside the Spark executor.

Figure 1-109 Topology of CarbonData



Data stored in CarbonData Table is divided into several CarbonData data files. Each time when data is queried, CarbonData Engine reads and filters data sets. CarbonData Engine runs as a part of the Spark Executor process and is responsible for handling a subset of data file blocks.

Table data is stored in HDFS. Nodes in the same Spark cluster can be used as HDFS data nodes.

CarbonData Features

- SQL: CarbonData is compatible with Spark SQL and supports SQL query operations performed on Spark SQL.
- Simple Table dataset definition: CarbonData allows you to define and create datasets by using user-friendly Data Definition Language (DDL) statements. CarbonData DDL is flexible and easy to use, and can define complex tables.
- Easy data management: CarbonData provides various data management functions for data loading and maintenance. CarbonData supports bulk loading of historical data and incremental loading of new data. Loaded data can be deleted based on load time and a specific loading operation can be undone.
- CarbonData file format is a columnar store in HDFS. This format has many new column-based file storage features, such as table splitting and data compression. CarbonData has the following characteristics:
  - Stores data along with index: Significantly accelerates query performance and reduces the I/O scans and CPU resources, when there are filters in the query. CarbonData index consists of multiple levels of indices. A processing framework can leverage this index to reduce the task that needs to be schedules and processed, and it can also perform skip scan in more finer grain unit (called blocklet) in task side scanning instead of scanning the whole file.
  - Operable encoded data: Through supporting efficient compression and global encoding schemes, CarbonData can query on compressed/encoded

data. The data can be converted just before returning the results to the users, which is called late materialized.

- Supports various use cases with one single data format: like interactive OLAP-style query, sequential access (big scan), and random access (narrow scan).

Key Technologies and Advantages of CarbonData

- Quick query response: CarbonData features high-performance query. The query speed of CarbonData is 10 times of that of Spark SQL. It uses dedicated data formats and applies multiple index technologies, global dictionary code, and multiple push-down optimizations, providing quick response to TB-level data queries.
- Efficient data compression: CarbonData compresses data by combining the lightweight and heavyweight compression algorithms. This significantly saves 60% to 80% data storage space and the hardware storage cost.

CarbonData Index Cache Server

To solve the pressure and problems brought by the increasing data volume to the driver, an independent index cache server is introduced to separate the index from the Spark application side of Carbon query. All index content is managed by the index cache server. Spark applications obtain required index data in RPC mode. In this way, a large amount of memory on the service side is released so that services are not affected by the cluster scale and the performance or functions are not affected.

1.3.24.5.2 Optimizing SQL Query of Data of Multiple Sources

Scenario

Enterprises usually store massive data, such as from various databases and warehouses, for management and information collection. However, diversified data sources, hybrid dataset structures, and scattered data storage lower query efficiency.

The open source Spark only supports simple filter pushdown during querying of multi-source data. The SQL engine performance is deteriorated due of a large amount of unnecessary data transmission. The pushdown function is enhanced, so that **aggregate**, complex **projection**, and complex **predicate** can be pushed to data sources, reducing unnecessary data transmission and improving query performance.

Only the JDBC data source supports pushdown of query operations, such as **aggregate**, **projection**, **predicate**, **aggregate over inner join**, and **aggregate over union all**. All pushdown operations can be enabled based on your requirements.

Table 1-22 Enhanced query of cross-source query

Module	Before Enhancement	After Enhancement
aggregate	The pushdown of **aggregate** is not supported.	• Aggregation functions including **sum**, **avg**, **max**, **min**, and **count** are supported. Example: select count(*) from table • Internal expressions of aggregation functions are supported. Example: select sum(a+b) from table • Calculation of aggregation functions is supported. Example: select avg(a) + max(b) from table • Pushdown of **having** is supported. Example: select sum(a) from table where a>0 group by b having sum(a)>10 • Pushdown of some functions is supported. Pushdown of lines in mathematics, time, and string functions, such as **abs()**, **month()**, and **length()** are supported. In addition to the preceding built-in functions, you can run the **SET** command to add functions supported by data sources. Example: select sum(abs(a)) from table • Pushdown of **limit** and **order by** after **aggregate** is supported. However, the pushdown is not supported in Oracle, because Oracle does not support **limit**. Example: select sum(a) from table where a>0 group by b order by sum(a) limit 5
projection	Only pushdown of simple **projection** is supported. Example: select a, b from table	• Complex expressions can be pushed down. Example: select (a+b)*c from table • Some functions can be pushed down. For details, see the description below the table. Example: select length(a)+abs(b) from table • Pushdown of **limit** and **order by** after **projection** is supported. Example: select a, b+c from table order by a limit 3

Module	Before Enhancement	After Enhancement
predicate	Only simple filtering with the column name on the left of the operator and values on the right is supported. Example: select * from table where a>0 or b in ("aaa", "bbb")	• Complex expression pushdown is supported. Example: select * from table where a +b>c*d or a/c in (1, 2, 3) • Some functions can be pushed down. For details, see the description below the table. Example: select * from table where length(a)>5
aggregate over inner join	Related data from the two tables must be loaded to Spark. The join operation must be performed before the **aggregate** operation.	The following functions are supported: • Aggregation functions including **sum**, **avg**, **max**, **min**, and **count** are supported. • All **aggregate** operations can be performed in a same table. The **group by** operations can be performed on one or two tables and only inner join is supported. The following scenarios are not supported: • **aggregate** cannot be pushed down from both the left- and right-join tables. • **aggregate** contains operations, for example, sum(a+b). • **aggregate** operations, for example, sum(a)+min(b).
aggregate over union all	Related data from the two tables must be loaded to Spark. **union** must be performed before **aggregate**.	Supported scenarios: Aggregation functions including **sum**, **avg**, **max**, **min**, and **count** are supported. Unsupported scenarios: • **aggregate** contains operations, for example, sum(a+b). • **aggregate** operations, for example, sum(a)+min(b).

Precautions

- If external data source is Hive, query operation cannot be performed on foreign tables created by Spark.
- Only MySQL and MPPDB data sources are supported.

1.3.25 Tez

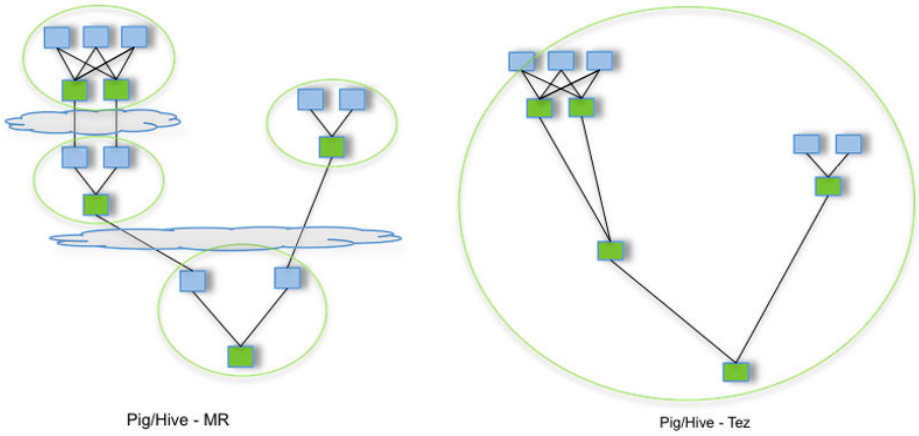
Tez is Apache's latest open source computing framework that supports Directed Acyclic Graph (DAG) jobs. It can convert multiple dependent jobs into one job, greatly improving the performance of DAG jobs. If projects like Hive use Tez instead of MapReduce as the backbone of data processing, response time will be significantly reduced. Tez is built on YARN and can run MapReduce jobs without any modification.

MRS uses Tez as the default execution engine of Hive. Tez remarkably surpasses the original MapReduce computing engine in terms of execution efficiency.

Relationship Between Tez and MapReduce

Tez uses a DAG to organize MapReduce tasks. In the DAG, a node is an RDD, and an edge indicates an operation on the RDD. The core idea is to further split Map tasks and Reduce tasks. A Map task is split into the Input-Processor-Sort-Merge-Output tasks, and the Reduce task is split into the Input-Shuffle-Sort-Merge-Process-output tasks. Tez flexibly regroups several small tasks to form a large DAG job.

Figure 1-110 Processes for submitting tasks using Hive on MapReduce and Hive on Tez



A Hive on MapReduce task contains multiple MapReduce tasks. Each task stores intermediate results to HDFS. The reducer in the previous step provides data for the mapper in the next step. A Hive on Tez task can complete the same processing process in only one task, and HDFS does not need to be accessed between tasks.

Relationship Between Tez and Yarn

Tez is a computing framework running on Yarn. The runtime environment consists of ResourceManager and ApplicationMaster of Yarn. ResourceManager is a brand

new resource manager system, and ApplicationMaster is responsible for cutting MapReduce job data, assigning tasks, applying for resources, scheduling tasks, and tolerating faults. In addition, TezUI depends on TimelineServer provided by Yarn to display the running process of Tez tasks.

1.3.26 YARN

1.3.26.1 YARN Basic Principles

The Apache open source community introduces the unified resource management framework YARN to share Hadoop clusters, improve their scalability and reliability, and eliminate a performance bottleneck of JobTracker in the early MapReduce framework.

The fundamental idea of YARN is to split up the two major functionalities of the JobTracker, resource management and job scheduling/monitoring, into separate daemons. The idea is to have a global ResourceManager (RM) and per-application ApplicationMaster (AM).

NOTE

An application is either a single job in the classical sense of MapReduce jobs or a Directed Acyclic Graph (DAG) of jobs.

Architecture

ResourceManager is the essence of the layered structure of YARN. This entity controls an entire cluster and manages the allocation of applications to underlying compute resources. The ResourceManager carefully allocates various resources (compute, memory, bandwidth, and so on) to underlying NodeManagers (YARN's per-node agents). The ResourceManager also works with ApplicationMasters to allocate resources, and works with the NodeManagers to start and monitor their underlying applications. In this context, the ApplicationMaster has taken some of the role of the prior TaskTracker, and the ResourceManager has taken the role of the JobTracker.

ApplicationMaster manages each instance of an application running in YARN. The ApplicationMaster negotiates resources from the ResourceManager and works with the NodeManagers to monitor container execution and resource usage (CPU and memory resource allocation).

The NodeManager manages each node in a YARN cluster. The NodeManager provides per-node services in a cluster, from overseeing the management of a container over its lifecycle to monitoring resources and tracking the health of its nodes. MRv1 manages execution of the Map and Reduce tasks through slots, whereas the NodeManager manages abstract containers, which represent per-node resources available for a particular application.

Figure 1-111 Architecture

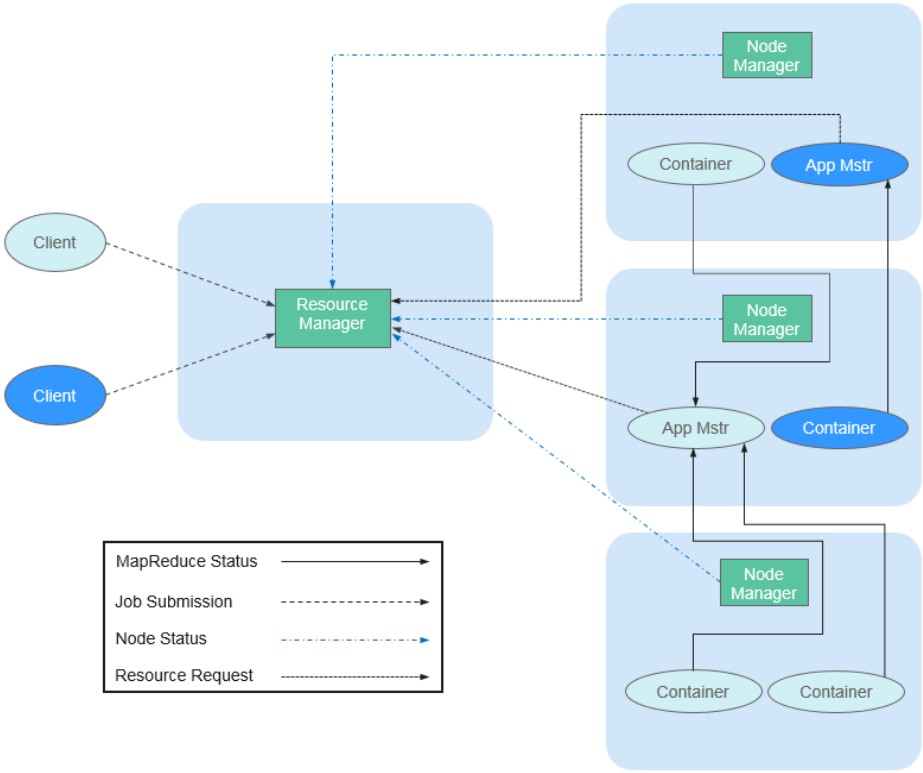


Table 1-23 describes the components shown in Figure 1-111.

Table 1-23 Architecture description

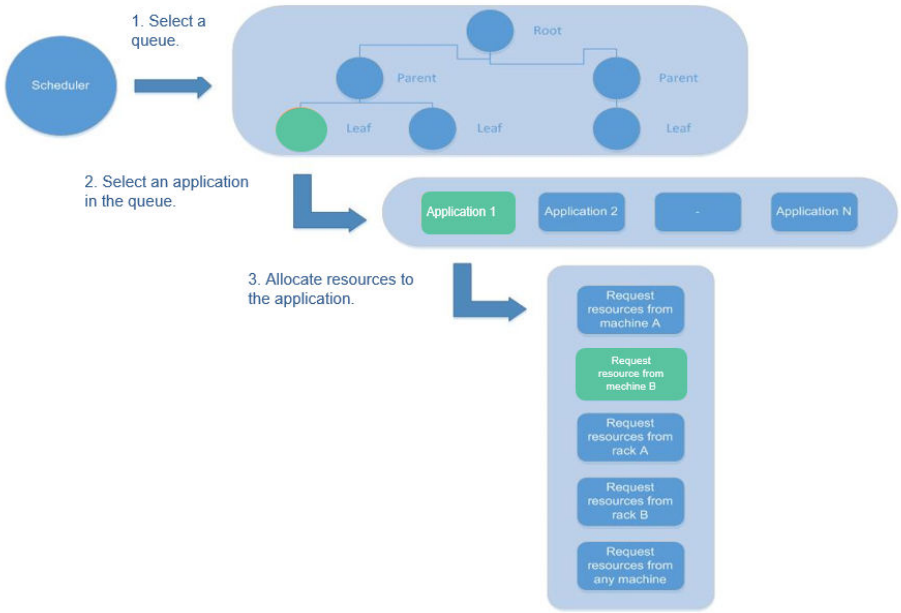
Name	Description
Client	Client of a YARN application. You can submit a task to ResourceManager and query the operating status of an application using the client.
ResourceManager(RM)	RM centrally manages and allocates all resources in the cluster. It receives resource reporting information from each node (NodeManager) and allocates resources to applications on the basis of the collected resources according a specified policy.
NodeManager(NM)	NM is the agent on each node of YARN. It manages the computing node in Hadoop cluster, establishes communication with ResourceManger, monitors the lifecycle of containers, monitors the usage of resources such as memory and CPU of each container, traces node health status, and manages logs and auxiliary services used by different applications.

Name	Description
ApplicationMaster(AM)	AM (App Mstr in the figure above) is responsible for all tasks through the lifcycle of in an application. The tasks include the following: Negotiate with an RM scheduler to obtain a resource; further allocate the obtained resources to internal tasks (secondary allocation of resources); communicate with the NM to start or stop tasks; monitor the running status of all tasks; and apply for resources for tasks again to restart the tasks when the tasks fail to be executed.
Container	A resource abstraction in YARN. It encapsulates multi-dimensional resources (including only memory and CPU) on a certain node. When ApplicationMaster applies for resources from ResourceManager, the ResourceManager returns resources to the ApplicationMaster in a container. YARN allocates one container for each task and the task can only use the resources encapsulated in the container.

In YARN, resource schedulers organize resources through hierarchical queues. This ensures that resources are allocated and shared among queues, thereby improving the usage of cluster resources. The core resource allocation model of Superior Scheduler is the same as that of Capacity Scheduler, as shown in the following figure.

A scheduler maintains queue information. You can submit applications to one or more queues. During each NM heartbeat, the scheduler selects a queue according to a specific scheduling rule, selects an application in the queue, and then allocates resources to the application. If resources fail to be allocated to the application due to the limit of some parameters, the scheduler will select another application. After the selection, the scheduler processes the resource request of this application. The scheduler gives priority to the requests for local resources first, and then for resources on the same rack, and finally for resources from any machine.

Figure 1-112 Resource allocation model



Principle

The new Hadoop MapReduce framework is named MRv2 or YARN. YARN consists of ResourceManager, ApplicationMaster, and NodeManager.

- ResourceManager is a global resource manager that manages and allocates resources in the system. ResourceManager consists of Scheduler and Applications Manager.
  - Scheduler allocates system resources to all running applications based on the restrictions such as capacity and queue (for example, allocates a certain amount of resources for a queue and executes a specific number of jobs). It allocates resources based on the demand of applications, with container being used as the resource allocation unit. Functioning as a dynamic resource allocation unit, Container encapsulates memory, CPU, disk, and network resources, thereby limiting the resource consumed by each task. In addition, the Scheduler is a pluggable component. You can design new schedulers as required. YARN provides multiple directly available schedulers, such as Fair Scheduler and Capacity Scheduler.
  - Applications Manager manages all applications in the system and involves submitting applications, negotiating with schedulers about resources, enabling and monitoring ApplicationMaster, and restarting ApplicationMaster upon the startup failure.
- NodeManager is the resource and task manager of each node. On one hand, NodeManager periodically reports resource usage of the local node and the running status of each Container to ResourceManager. On the other hand, NodeManager receives and processes requests from ApplicationMaster for starting or stopping Containers.
- ApplicationMaster is responsible for all tasks through the lifecycle of an application, these channels include the following:
  - Negotiate with the RM scheduler to obtain resources.

  - Assign resources to internal components (secondary allocation of resources).
  - Communicates with NodeManager to start or stop tasks.
  - Monitor the running status of all tasks, and applies for resources again for tasks when tasks fail to run to restart the tasks.

Capacity Scheduler Principle

Capacity Scheduler is a multi-user scheduler. It allocates resources by queue and sets the minimum/maximum resources that can be used for each queue. In addition, the upper limit of resource usage is set for each user to prevent resource abuse. Remaining resources of a queue can be temporarily shared with other queues.

Capacity Scheduler supports multiple queues. It configures a certain amount of resources for each queue and adopts the first-in-first-out queuing (FIFO) scheduling policy. To prevent one user's applications from exclusively using the resources in a queue, Capacity Scheduler sets a limit on the number of resources used by jobs submitted by one user. During scheduling, Capacity Scheduler first calculates the number of resources required for each queue, and selects the queue that requires the least resources. Then, it allocates resources based on the job priority and time that jobs are submitted as well as the limit on resources and memory. Capacity Scheduler supports the following features:

- Guaranteed capacity: As the MRS cluster administrator, you can set the lower and upper limits of resource usage for each queue. All applications submitted to this queue share the resources.
- High flexibility: Temporarily, the remaining resources of a queue can be shared with other queues. However, such resources must be released in case of new application submission to the queue. Such flexible resource allocation helps notably improve resource usage.
- Multi-tenancy: Multiple users can share a cluster, and multiple applications can run concurrently. To avoid exclusive resource usage by a single application, user, or queue, the MRS cluster administrator can add multiple constraints (for example, limit on concurrent tasks of a single application).
- Assured protection: An ACL list is provided for each queue to strictly limit user access. You can specify the users who can view your application status or control the applications. Additionally, the MRS cluster administrator can specify a queue administrator and a cluster system administrator.
- Dynamic update of configuration files: MRS cluster administrators can dynamically modify configuration parameters to manage clusters online.

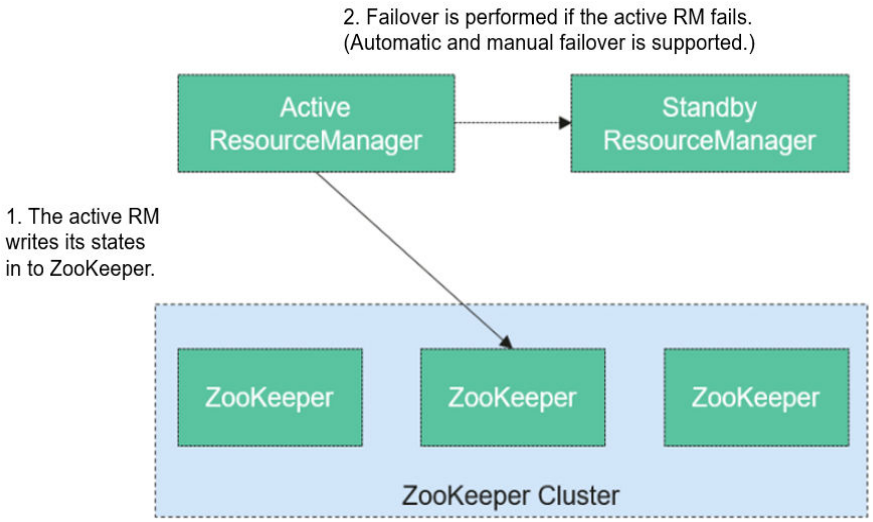
Each queue in Capacity Scheduler can limit the resource usage. However, the resource usage of a queue determines its priority when resources are allocated to queues, indicating that queues with smaller capacity are competitive. If the throughput of a cluster is big, delay scheduling enables an application to give up cross-machine or cross-rack scheduling, and to request local scheduling.

1.3.26.2 YARN HA Solution

HA Principles and Implementation Solution

ResourceManager in YARN manages resources and schedules tasks in the cluster. In versions earlier than Hadoop 2.4, SPOFs may occur on ResourceManager in the YARN cluster. The YARN HA solution uses redundant ResourceManager nodes to tackle challenges of service reliability and fault tolerance.

Figure 1-113 ResourceManager HA architecture



ResourceManager HA is achieved using active-standby ResourceManager nodes, as shown in **Figure 1-113**. Similar to the HDFS HA solution, the ResourceManager HA allows only one ResourceManager node to be in the active state at any time. When the active ResourceManager fails, the active-standby switchover can be triggered automatically or manually.

When the automatic failover function is not enabled, after the YARN cluster is enabled, MRS cluster administrators need to run the ***yarn rmadmin*** command to manually switch one of the ResourceManager nodes to the active state. Upon a planned maintenance event or a fault, they are expected to first demote the active ResourceManager to the standby state and the standby ResourceManager promote to the active state.

When automatic failover is enabled, a built-in ActiveStandbyElector that is based on ZooKeeper is used to decide which ResourceManager node should be the active one. When the active ResourceManager is faulty, another ResourceManager node is automatically selected to be the active one to take over the faulty node.

When ResourceManager nodes in the cluster are deployed in HA mode, the configuration **yarn-site.xml** used by clients needs to list all the ResourceManager nodes. The client (including ApplicationMaster and NodeManager) searches for the active ResourceManager in polling mode. That is, the client needs to provide the fault tolerance mechanism. If the active ResourceManager cannot be connected with, the client continuously searches for a new one in polling mode.

After the standby ResourceManager node becomes the active one, the upper-layer applications can recover to their status when the fault occurs. When

ResourceManager Restart is enabled, the restarted ResourceManager node loads the information of the previous active ResourceManager node, and takes over container status information on all NodeManager nodes to continue service running. In this way, status information can be saved by periodically executing checkpoint operations, avoiding data loss. Ensure that both active and standby ResourceManager nodes can access the status information. Currently, three methods are provided for sharing status information by file system (FileSystemRMStateStore), LevelDB database (LeveldbRMStateStore), and ZooKeeper (ZKRMStateStore). Among them, only ZKRMStateStore supports the Fencing mechanism. By default, Hadoop uses ZKRMStateStore.

1.3.26.3 Relationship Between YARN and Other Components

Relationship Between YARN and Spark

The Spark computing and scheduling can be implemented using YARN mode. Spark enjoys the compute resources provided by YARN clusters and runs tasks in a distributed way. Spark on YARN has two modes: YARN-cluster and YARN-client.

- YARN Cluster mode

  Figure 1-114 describes the operation framework.

  Figure 1-114 Spark on YARN-cluster operation framework

  Spark on YARN-cluster implementation process:

  a. The client generates the application information, and then sends the information to ResourceManager.

  b. ResourceManager allocates the first container (ApplicationMaster) to SparkApplication and starts the driver on the container.

  c. ApplicationMaster applies for resources from ResourceManager to run the container.

     ResourceManager allocates the containers to ApplicationMaster, which communicates with the related NodeManagers and starts the executor in the obtained container. After the executor is started, it registers with drivers and applies for tasks.

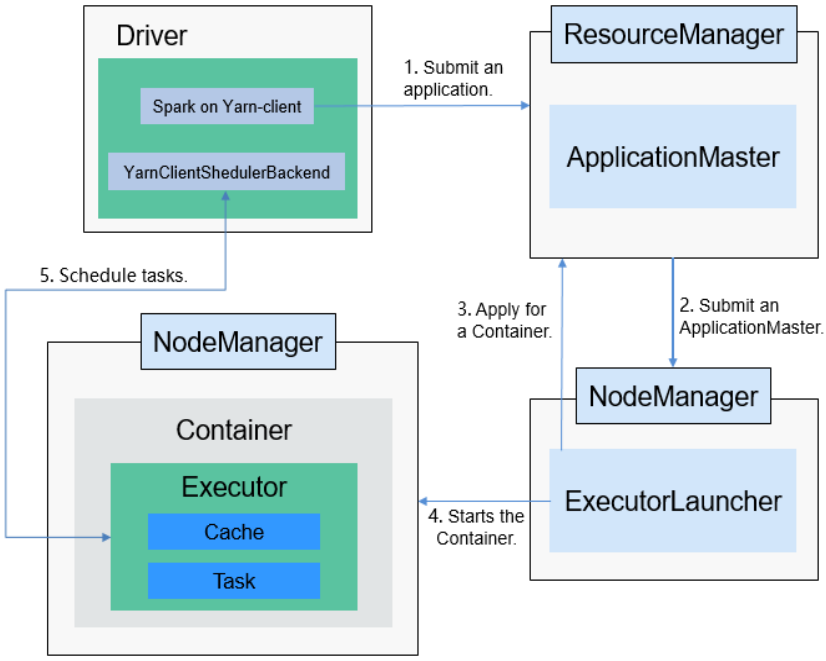
d. Drivers allocate tasks to the executors.

e. Executors run tasks and report the operating status to Drivers.

- YARN Client mode

  Figure 1-115 describes the operation framework.

  Figure 1-115 Spark on YARN-client operation framework



Spark on YARN-client implementation process:

NOTE

In YARN-client mode, the driver is deployed and started on the client. In YARN-client mode, the client of an earlier version is incompatible. You are advised to use the YARN-cluster mode.

a. The client sends the Spark application request to ResourceManager, then ResourceManager returns the results. The results include information such as Application ID and the maximum and minimum available resources. The client packages all information required to start ApplicationMaster, and sends the information to ResourceManager.

b. After receiving the request, ResourceManager finds a proper node for ApplicationMaster and starts it on this node. ApplicationMaster is a role in YARN, and the process name in Spark is ExecutorLauncher.

c. Based on the resource requirements of each task, ApplicationMaster can apply for a series of containers to run tasks from ResourceManager.

d. After receiving the newly allocated container list (from ResourceManager), ApplicationMaster sends information to the related NodeManagers to start the containers.

   ResourceManager allocates the containers to ApplicationMaster, which communicates with the related NodeManagers and starts the executor in the obtained container. After the executor is started, it registers with drivers and applies for tasks.

NOTE

Running containers are not suspended and resources are not released.

e. Drivers allocate tasks to the executors. Executors run tasks and report the operating status to Drivers.

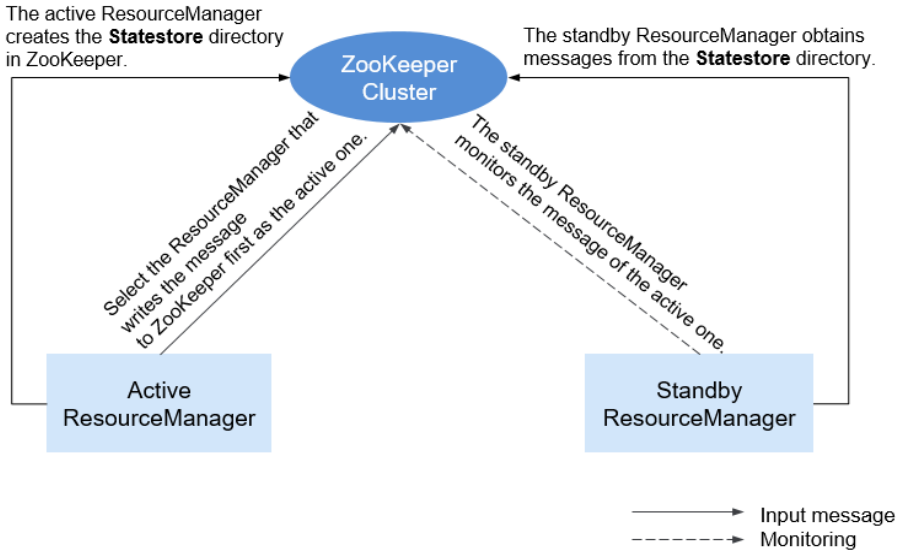
Relationship Between YARN and MapReduce

MapReduce is a computing framework running on YARN, which is used for batch processing. MRv1 is implemented based on MapReduce in Hadoop 1.0, which is composed of programming models (new and old programming APIs), running environment (JobTracker and TaskTracker), and data processing engine (MapTask and ReduceTask). This framework is still weak in scalability, fault tolerance (JobTracker SPOF), and compatibility with multiple frameworks. (Currently, only the MapReduce computing framework is supported.) MRv2 is implemented based on MapReduce in Hadoop 2.0. The source code reuses MRv1 programming models and data processing engine implementation, and the running environment is composed of ResourceManager and ApplicationMaster. ResourceManager is a brand new resource manager system, and ApplicationMaster is responsible for cutting MapReduce job data, assigning tasks, applying for resources, scheduling tasks, and tolerating faults.

Relationship Between YARN and ZooKeeper

Figure 1-116 shows the relationship between ZooKeeper and YARN.

Figure 1-116 Relationship Between ZooKeeper and YARN



1. When the system is started, ResourceManager attempts to write state information to ZooKeeper. ResourceManager that first writes state information to ZooKeeper is selected as the active ResourceManager, and others are standby ResourceManagers. The standby ResourceManagers periodically monitor active ResourceManager election information in ZooKeeper.

2. The active ResourceManager creates the **Statestore** directory in ZooKeeper to store application information. If the active ResourceManager is faulty, the standby ResourceManager obtains application information from the **Statestore** directory and restores the data.

Relationship Between YARN and Tez

The Hive on Tez job information requires the TimeLine Server capability of YARN so that Hive tasks can display the current and historical status of applications, facilitating storage and retrieval.

1.3.26.4 Yarn Enhanced Open Source Features

Priority-based task scheduling

In the native Yarn resource scheduling mechanism, if the whole Hadoop cluster resources are occupied by those MapReduce jobs submitted earlier, jobs submitted later will be kept in pending state until all running jobs are executed and resources are released.

The MRS cluster provides the task priority scheduling mechanism. With this feature, you can define jobs of different priorities. Jobs of high priority can preempt resources released from jobs of low priority though the high-priority jobs are submitted later. The low-priority jobs that are not started will be suspended unless those jobs of high priority are completed and resources are released, then they can properly be started.

This feature enables services to control computing jobs more flexibly, thereby achieving higher cluster resource utilization.

NOTE

Container reuse is in conflict with task priority scheduling. If container reuse is enabled, resources are being occupied, and task priority scheduling does not take effect.

Yarn Permission Control

The permission mechanism of Hadoop Yarn is implemented through ACLs. The following describes how to grant different permission control to different users:

- Admin ACL

  An O&M administrator is specified for the YARN cluster. The Admin ACL is determined by **yarn.admin.acl**. The cluster O&M administrator can access the ResourceManager web UI and operate NodeManager nodes, queues, and NodeLabel, **but cannot submit tasks**.

- Queue ACL

  To facilitate user management in the cluster, users or user groups are divided into several queues to which each user and user group belongs. Each queue contains permissions to submit and manage applications (for example, terminate any application).

Open source functions:

Currently, Yarn supports the following roles for users:

- Cluster O&M administrator
- Queue administrator
- Common user

However, the APIs (such as the web UI, REST API, and Java API) provided by Yarn do not support role-specific permission control. Therefore, all users have the permission to access the application and cluster information, which does not meet the isolation requirements in the multi-tenant scenario.

This is an enhanced function.

In security mode, permission management is enhanced for the APIs such as web UI, REST API, and Java API provided by Yarn. Permission control can be performed based on user roles.

Role-based permissions are as follows:

- Cluster O&M administrator: performs management operations in the Yarn cluster, such as accessing the ResourceManager web UI, refreshing queues, setting NodeLabel, and performing active/standby switchover.
- Queue administrator: has the permission to modify and view queues managed by the Yarn cluster.
- Common user: has the permission to modify and view self-submitted applications in the Yarn cluster.

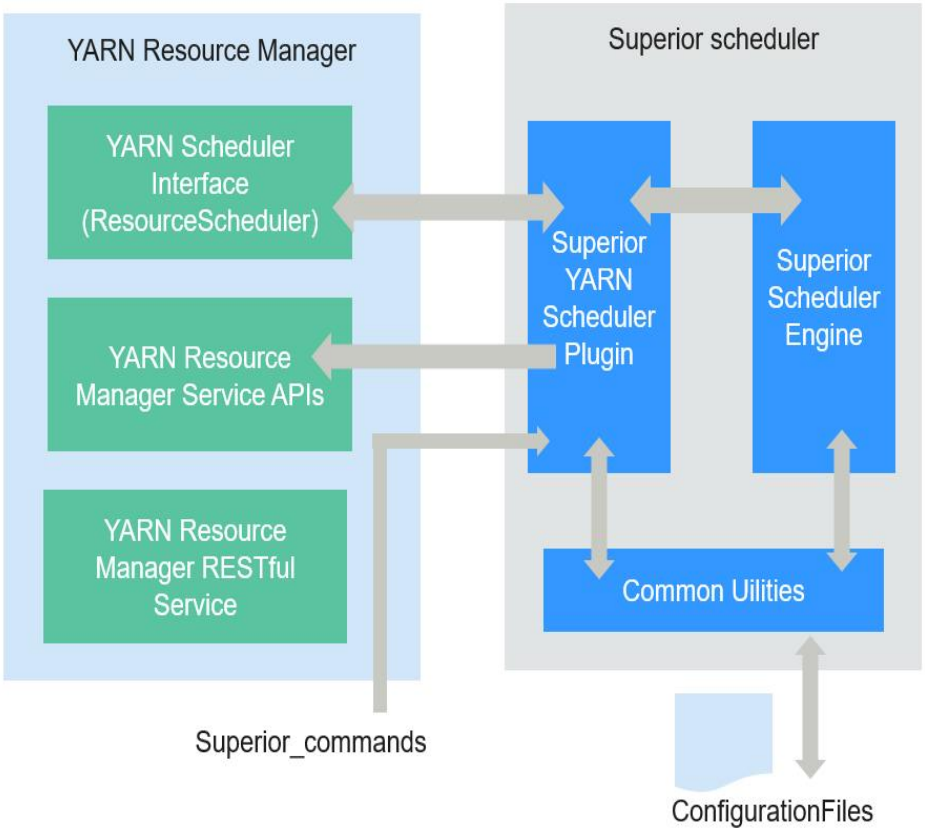
Superior Scheduler Principle (Self-developed)

Superior Scheduler is a scheduling engine designed for the Hadoop Yarn distributed resource management system. It is a high-performance and enterprise-level scheduler designed for converged resource pools and multi-tenant service requirements.

Superior Scheduler achieves all functions of open source schedulers, Fair Scheduler, and Capacity Scheduler. Compared with the open source schedulers, Superior Scheduler is enhanced in the enterprise multi-tenant resource scheduling policy, resource isolation and sharing among users in a tenant, scheduling performance, system resource usage, and cluster scalability. Superior Scheduler is designed to replace open source schedulers.

Similar to open source Fair Scheduler and Capacity Scheduler, Superior Scheduler follows the Yarn scheduler plugin API to interact with Yarn ResourceManager to offer resource scheduling functionalities. **Figure 1-117** shows the overall system diagram.

Figure 1-117 Internal architecture of Superior Scheduler



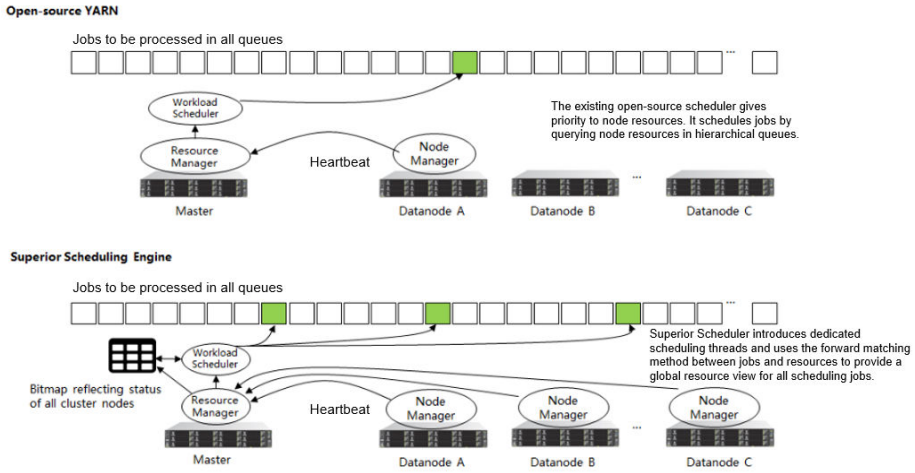
In **Figure 1-117**, Superior Scheduler consists of the following modules:

- Superior Scheduler Engine is a high performance scheduler engine with rich scheduling policies.
- Superior Yarn Scheduler Plugin functions as a bridge between Yarn ResourceManager and Superior Scheduler Engine and interacts with Yarn ResourceManager.

  The scheduling principle of open source schedulers is that resources match jobs based on the heartbeats of computing nodes. Specifically, each computing node periodically sends heartbeat messages to ResourceManager of Yarn to notify the node status and starts the scheduler to assign jobs to the node itself. In this scheduling mechanism, the scheduling period depends on the heartbeat. If the cluster scale increases, bottleneck on system scalability and scheduling performance may occur. In addition, because resources match jobs, the scheduling accuracy of an open source scheduler is limited. For example, data affinity is random and the system does not support load-based scheduling policies. The scheduler may not make the best choice due to lack of the global resource view when selecting jobs.

  Superior Scheduler adopts multiple scheduling mechanisms. There are dedicated scheduling threads in Superior Scheduler, separating heartbeats with scheduling and preventing system heartbeat storms. Additionally, Superior Scheduler matches jobs with resources, providing each scheduled job with a global resource view and increasing the scheduling accuracy. Compared with the open source scheduler, Superior Scheduler excels in system throughput, resource usage, and data affinity.

Figure 1-118 Comparison of Superior Scheduler with open source schedulers



Apart from the enhanced system throughput and utilization, Superior Scheduler provides following major scheduling features:

- Multiple resource pools

  Multiple resource pools help logically divide cluster resources and share them among multiple tenants or queues. The division of resource pools supports heterogeneous resources. Resource pools can be divided exactly according to requirements on the application resource isolation. You can configure further policies for different queues in a pool.

- Multi-tenant scheduling (**reserve**, **min**, **share**, and **max**) in each resource pool

  Superior Scheduler provides flexible hierarchical multi-tenant scheduling policy. Different policies can be configured for different tenants or queues that can access different resource pools. The following figure lists supported policies:

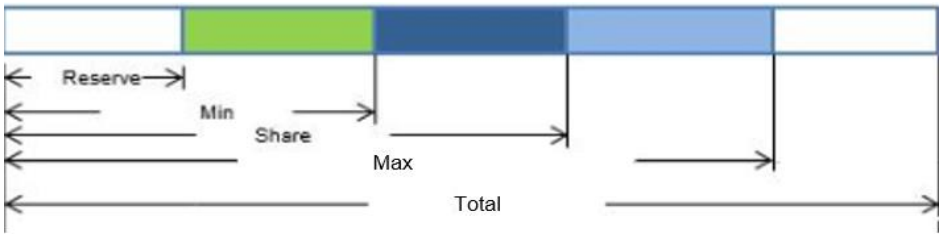
  Table 1-24 Policy description

Name	Description
reserve	This policy is used to reserve resources for a tenant. Even though tenant has no jobs available, other tenant cannot use the reserved resource. The value can be a percentage or an absolute value. If both the percentage and absolute value are configured, the percentage is automatically calculated into an absolute value, and the larger value is used. The default **reserve** value is **0**. Compared with the method of specifying a dedicated resource pool and hosts, the **reserve** policy provides a flexible floating reservation function. In addition, because no specific hosts are specified, the data affinity for calculation is improved and the impact by the faulty hosts is avoided.

Name	Description
min	This policy allows preemption of minimum resources. Other tenants can use these resources, but the current tenant has the priority to use them. The value can be a percentage or an absolute value. If both the percentage and absolute value are configured, the percentage is automatically calculated into an absolute value, and the larger value is used. The default value is **0**.
share	This policy is used for shared resources that cannot be preempted. To use these resources, the current tenant needs to wait for other tenants to complete jobs and release resources. The value can be a percentage or an absolute value.
max	This policy is used for the maximum resources that can be utilized. The tenant cannot obtain more resources than the allowed maximum value. The value can be a percentage or an absolute value. If both the percentage and absolute value are configured, the percentage is automatically calculated into an absolute value, and the larger value is used. By default value, there is no restriction on resources.

Figure 1-119 shows the tenant resource allocation policy.

Figure 1-119 Resource scheduling policies



NOTE

In the above figure, **Total** indicates the total number of resources, not the scheduling policy.

Compared with open source schedulers, Superior Scheduler supports both percentage and absolute value of tenants for allocating resources, flexibly addressing resource scheduling requirements of enterprise-level tenants. For example, resources can be allocated according to the absolute value of level-1 tenants, avoiding impact caused by changes of cluster scale. However, resources can be allocated according to the allocation percentage of sub-tenants, improving resource usages in the level-1 tenant.

- Heterogeneous and multi-dimensional resource scheduling

  Superior Scheduler supports following functions except CPU and memory scheduling:

  - Node labels can be used to identify multi-dimensional attributes of nodes such as **GPU_ENABLED** and **SSD_ENABLED**, and can be scheduled based on these labels.
  - Resource pools can be used to group resources of the same type and allocate them to specific tenants or queues.

- Fair scheduling of multiple users in a tenant

  In a leaf tenant, multiple users can use the same queue to submit jobs. Compared with the open source schedulers, Superior Scheduler supports configuring flexible resource sharing policy among different users in a same tenant. For example, VIP users can be configured with higher resource access weight.

- Data locality aware scheduling

  Superior Scheduler adopts the job-to-node scheduling policy. That is, Superior Scheduler attempts to schedule specified jobs between available nodes so that the selected node is suitable for the specified jobs. By doing so, the scheduler will have an overall view of the cluster and data. Localization is ensured if there is an opportunity to place tasks closer to the data. The open source scheduler uses the node-to-job scheduling policy to match the appropriate jobs to a given node.

- Dynamic resource reservation during container scheduling

  In a heterogeneous and diversified computing environment, some containers need more resources or multiple resources. For example, Spark job may require large memory. When such containers compete with containers requiring fewer resources, containers requiring more resources may not obtain sufficient resources within a reasonable period. Open source schedulers allocate resources to jobs, which may cause unreasonable resource reservation for these jobs. This mechanism leads to the waste of overall system resources. Superior Scheduler differs from open source schedulers in following aspects:

  - Requirement-based matching: Superior Scheduler schedules jobs to nodes and selects appropriate nodes to reserve resources to improve the startup time of containers and avoid waste.
  - Tenant rebalancing: When the reservation logic is enabled, the open source schedulers do not comply with the configured sharing policy. Superior Scheduler uses different methods. In each scheduling period, Superior Scheduler traverses all tenants and attempts to balance resources based on the multi-tenant policy. In addition, Superior Scheduler attempts to meet all policies (**reserve**, **min**, and **share**) to release reserved resources and direct available resources to other containers that should obtain resources under different tenants.

- Dynamic queue status control (**Open**/**Closed**/**Active**/**Inactive**)

  Multiple queue statuses are supported, helping MRS cluster administrators manage and maintain multiple tenants.

  - Open status (**Open/Closed**): If the status is **Open** by default, applications submitted to the queue are accepted. If the status is **Closed**, no application is accepted.
  - Active status (**Active/Inactive**): If the status is **Active** by default, resources can be scheduled and allocated to applications in the tenant. Resources will not be scheduled to queues in **Inactive** status.

- Application pending reason
  If the application is not started, provide the job pending reasons.

Table 1-25 describes the comparison result of Superior Scheduler and Yarn open source schedulers.

Table 1-25 Comparative analysis

Scheduling	Yarn Open Source Scheduler	Superior Scheduler
Multi-tenant scheduling	In homogeneous clusters, either Capacity Scheduler or Fair Scheduler can be selected and the cluster does not support Fair Scheduler. Capacity Scheduler supports the scheduling by percentage and Fair Scheduler supports the scheduling by absolute value.	• Supports heterogeneous clusters and multiple resource pools. • Supports **reservation** to ensure direct access to resources.
Data locality aware scheduling	The node-to-job scheduling policy reduces the success rate of data localization and potentially affects application execution performance.	The **job-to-node scheduling policy** can aware data location more accurately, and the job hit rate of data localization scheduling is higher.
Balanced scheduling based on load of hosts	Not supported	**Balanced scheduling can be achieved when Superior Scheduler considers the host load and resource allocation during scheduling.**
Fair scheduling of multiple users in a tenant	Not supported	Supports keywords **default** and **others**.
Job waiting reason	Not supported	Job waiting reasons illustrate why a job needs to wait.

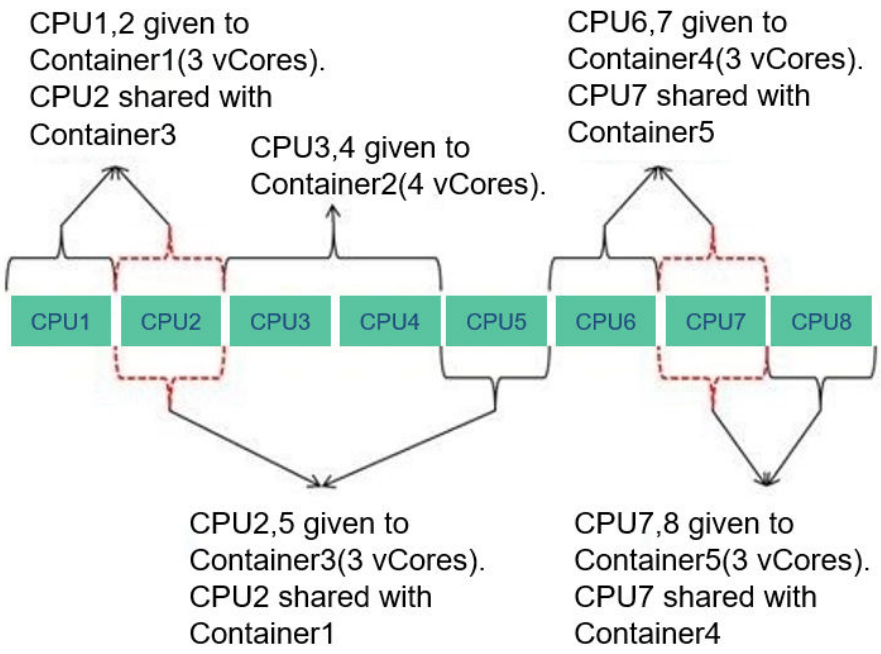
In conclusion, Superior Scheduler is a high-performance scheduler with various scheduling policies and is better than Capacity Scheduler in terms of functionality, performance, resource usage, and scalability.

CPU Hard Isolation

Yarn cannot strictly control the CPU resources used by each container. When the CPU subsystem is used, a container may occupy excessive resources. Therefore, CPUset is used to control resource allocation.

To solve this problem, the CPU resources are allocated to each container based on the ratio of virtual cores (vCores) to physical cores. If a container requires an entire physical core, the container has it. If a container needs only some physical cores, several containers may share the same physical core. The following figure shows an example of the CPU quota. The given ratio of vCores to physical cores is 2:1.

Figure 1-120 CPU quota

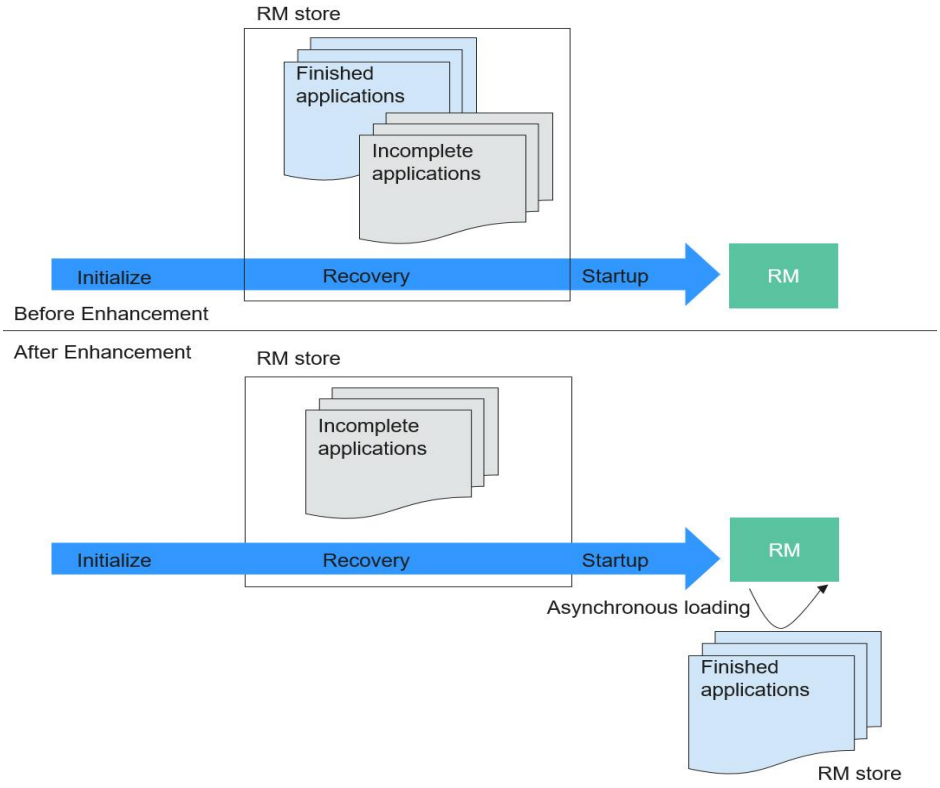


Enhanced Open Source Feature: Optimizing Restart Performance

Generally, the recovered ResourceManager can obtain running and completed applications. However, a large number of completed applications may cause problems such as slow startup and long HA switchover/restart time of ResourceManagers.

To speed up the startup, obtain the list of unfinished applications before starting the ResourceManagers. In this case, the completed application continues to be recovered in the background asynchronous thread. The following figure shows how the ResourceManager recovery starts.

Figure 1-121 Starting the ResourceManager recovery



1.3.27 ZooKeeper

1.3.27.1 ZooKeeper Basic Principles

Overview

ZooKeeper is a distributed, highly available coordination service. ZooKeeper is used to provide following functions:

- Prevents the system from SPOFs and provides reliable services for applications.
- Provides distributed coordination services and manages configuration information.

Architecture

Nodes in a ZooKeeper cluster have three roles: Leader, Follower, and Observer, as shown in **Figure 1-122**. Generally, an odd number of (2N+1) ZooKeeper services need to be configured in the cluster, and at least (N+1) vote majority is required to successfully perform the write operation.

Figure 1-122 Architecture

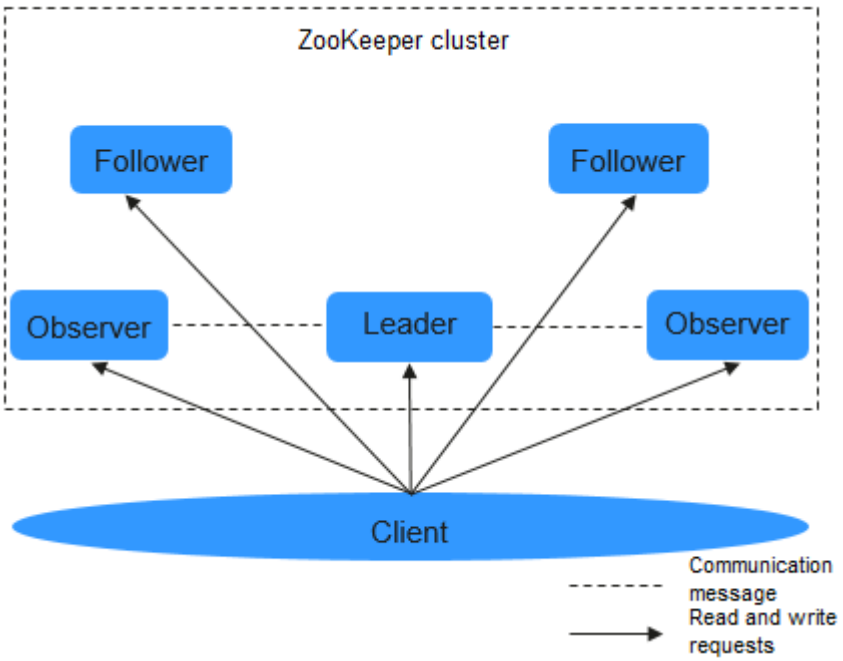


Table 1-26 describes the functions of each module shown in **Figure 1-122**.

Table 1-26 Architecture description

Name	Description
Leader	Only one node serves as the Leader in a ZooKeeper cluster. The Leader, elected by Followers using the ZooKeeper Atomic Broadcast (ZAB) protocol, receives and coordinates all write requests and synchronizes written information to Followers and Observers.
Follower	Follower has two functions: • Prevents SPOFs. A new Leader is elected from Followers when the Leader is faulty. • Processes read requests and interact with the Leader to process write requests.
Observer	The Observer does not take part in voting for election and write requests. It only processes read requests and forwards write requests to the Leader, increasing system processing efficiency.
Client	Reads and writes data from or to the ZooKeeper cluster. For example, HBase can serve as a ZooKeeper client and use the arbitration function of the ZooKeeper cluster to control the active/standby status of HMaster.

If security services are enabled in the cluster, authentication is required during the connection to ZooKeeper. The authentication modes are as follows:

- Keytab mode: You need to obtain a human-machine user from the MRS cluster administrator for MRS console login and authentication, and obtain the Keytab file of the user.
- Ticket mode: Obtain a human-machine user from the MRS cluster administrator for subsequent secure login, enable the renewable and forwardable functions of the Kerberos service, set the ticket update period, and restart Kerberos and related components.

  NOTE

  - By default, the validity period of the user password is 90 days. Therefore, the validity period of the obtained Keytab file is 90 days.
  - The parameters for enabling the renewable and forwardable functions and setting the ticket update interval are on the **System** tab of the Kerberos service configuration page. The ticket update interval can be set to **kdc_renew_lifetime** or **kdc_max_renewable_life** based on the actual situation.

Principles

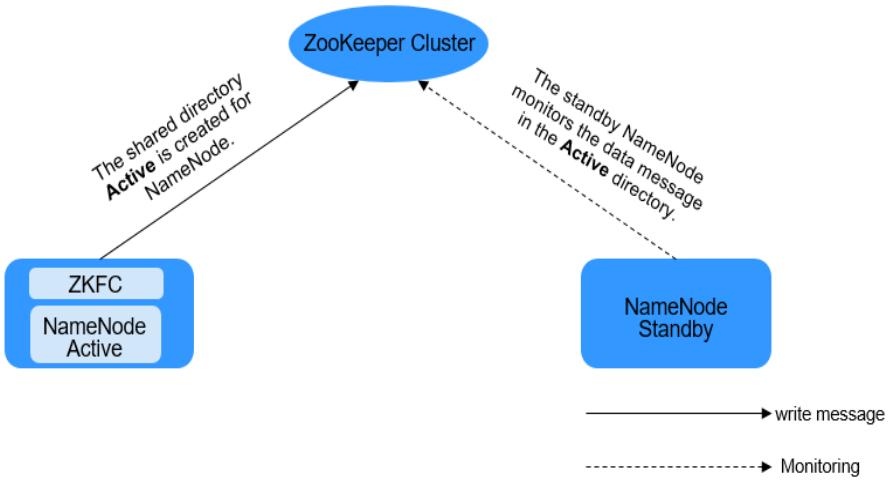
- **Write Request**
  a. After the Follower or Observer receives a write request, the Follower or Observer sends the request to the Leader.
  b. The Leader coordinates Followers to determine whether to accept the write request by voting.
  c. If more than half of voters return a write success message, the Leader submits the write request and returns a success message. Otherwise, a failure message is returned.
  d. The Follower or Observer returns the processing results.
- **Read-Only Request**
  The client directly reads data from the Leader, Follower, or Observer.

1.3.27.2 Relationship Between ZooKeeper and Other Components

Relationship Between ZooKeeper and HDFS

Figure 1-123 shows the relationship between ZooKeeper and HDFS.

Figure 1-123 Relationship between ZooKeeper and HDFS



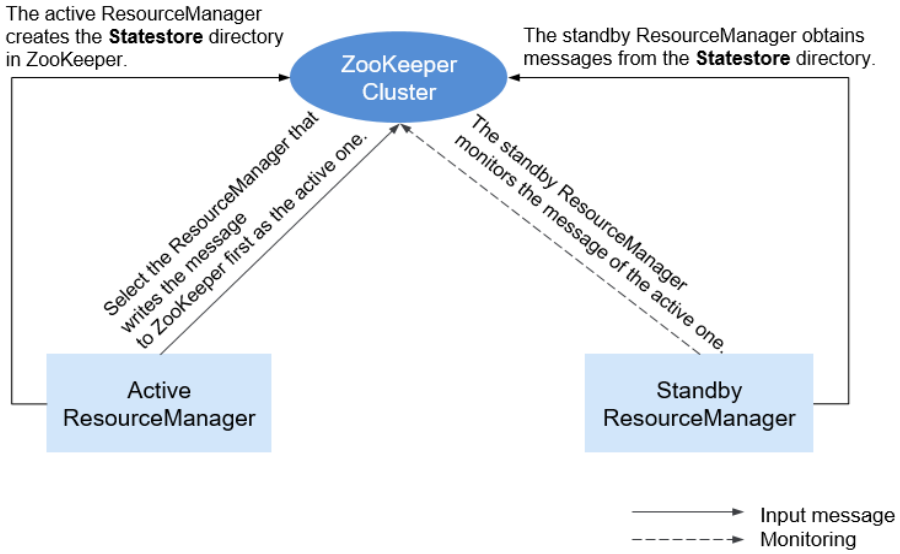
As the client of a ZooKeeper cluster, ZKFailoverController (ZKFC) monitors the status of NameNode. ZKFC is deployed only in the node where NameNode resides, and in both the active and standby HDFS NameNodes.

1. The ZKFC connects to ZooKeeper and saves information such as host names to ZooKeeper under the znode directory **/hadoop-ha**. NameNode that creates the directory first is considered as the active node, and the other is the standby node. NameNodes read the NameNode information periodically through ZooKeeper.
2. When the process of the active node ends abnormally, the standby NameNode detects changes in the **/hadoop-ha** directory through ZooKeeper, and then takes over the service of the active NameNode.

Relationship Between ZooKeeper and YARN

Figure 1-124 shows the relationship between ZooKeeper and YARN.

Figure 1-124 Relationship Between ZooKeeper and YARN

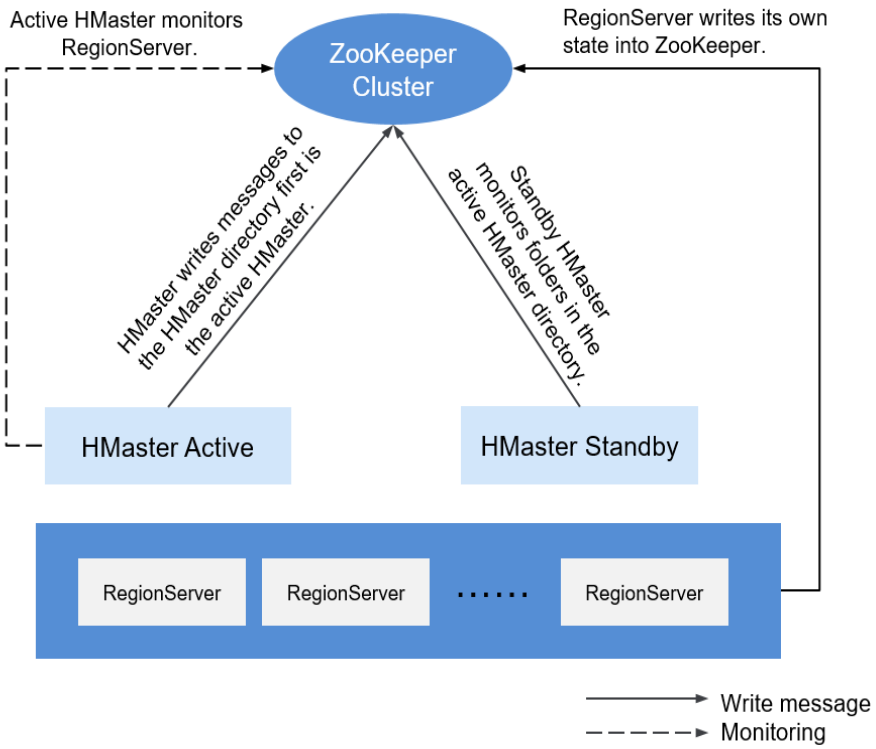


1. When the system is started, ResourceManager attempts to write state information to ZooKeeper. ResourceManager that first writes state information to ZooKeeper is selected as the active ResourceManager, and others are standby ResourceManagers. The standby ResourceManagers periodically monitor active ResourceManager election information in ZooKeeper.
2. The active ResourceManager creates the **Statestore** directory in ZooKeeper to store application information. If the active ResourceManager is faulty, the standby ResourceManager obtains application information from the **Statestore** directory and restores the data.

Relationship Between ZooKeeper and HBase

Figure 1-125 shows the relationship between ZooKeeper and HBase.

Figure 1-125 Relationship between ZooKeeper and HBase

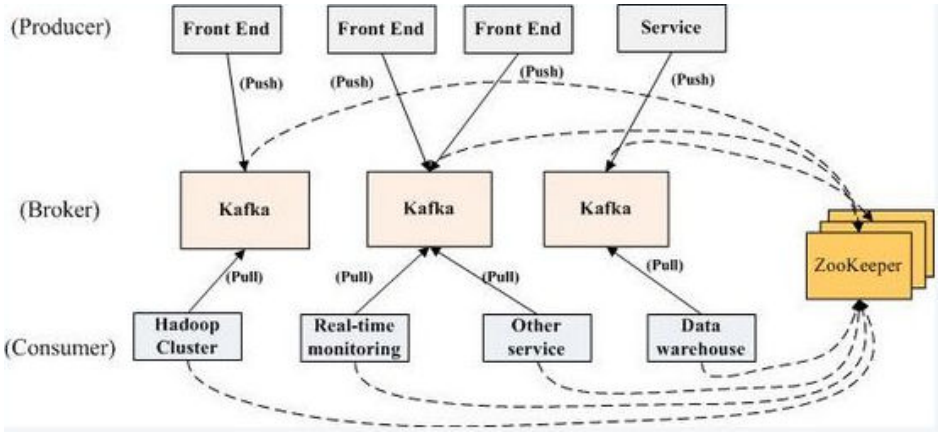


1. HRegionServer registers itself to ZooKeeper on Ephemeral node. ZooKeeper stores the HBase information, including the HBase metadata and HMaster addresses.
2. HMaster detects the health status of each HRegionServer using ZooKeeper, and monitors them.
3. HBase supports multiple HMaster nodes (like HDFS NameNodes). When the active HMatser is faulty, the standby HMaster obtains the state information about the entire cluster using ZooKeeper. That is, using ZooKeeper can avoid HBase SPOFs.

Relationship Between ZooKeeper and Kafka

Figure 1-126 shows the relationship between ZooKeeper and Kafka.

Figure 1-126 Relationship between ZooKeeper and Kafka



1. Broker uses ZooKeeper to register broker information and elect a partition leader.
2. The consumer uses ZooKeeper to register consumer information, including the partition list of consumer. In addition, ZooKeeper is used to discover the broker list, establish a socket connection with the partition leader, and obtain messages.

1.3.27.3 ZooKeeper Enhanced Open Source Features

Enhanced Log

In security mode, an ephemeral node is deleted as long as the session that created the node expires. Ephemeral node deletion is recorded in audit logs so that ephemeral node status can be obtained.

Usernames must be added to audit logs for all operations performed on ZooKeeper clients.

On the ZooKeeper client, create a znode, of which the Kerberos principal is **zkcli/hadoop.***<System domain name>***@***<System domain name>*.

For example, open the **<ZOO_LOG_DIR>/zookeeper_audit.log** file. The file content is as follows:

```
2016-12-28 14:17:10,505 | INFO  | CommitProcWorkThread-4 | session=0x12000007553b4903?
user=10.177.223.78,zkcli/hadoop.hadoop.com@HADOOP.COM?ip=10.177.223.78?operation=create znode?
target=ZooKeeperServer?znode=/test1?result=success
2016-12-28 14:17:10,530 | INFO  | CommitProcWorkThread-4 | session=0x12000007553b4903?
user=10.177.223.78,zkcli/hadoop.hadoop.com@HADOOP.COM?ip=10.177.223.78?operation=create znode?
target=ZooKeeperServer?znode=/test2?result=success
2016-12-28 14:17:10,550 | INFO  | CommitProcWorkThread-4 | session=0x12000007553b4903?
user=10.177.223.78,zkcli/hadoop.hadoop.com@HADOOP.COM?ip=10.177.223.78?operation=create znode?
target=ZooKeeperServer?znode=/test3?result=success
2016-12-28 14:17:10,570 | INFO  | CommitProcWorkThread-4 | session=0x12000007553b4903?
user=10.177.223.78,zkcli/hadoop.hadoop.com@HADOOP.COM?ip=10.177.223.78?operation=create znode?
target=ZooKeeperServer?znode=/test4?result=success
2016-12-28 14:17:10,592 | INFO  | CommitProcWorkThread-4 | session=0x12000007553b4903?
user=10.177.223.78,zkcli/hadoop.hadoop.com@HADOOP.COM?ip=10.177.223.78?operation=create znode?
target=ZooKeeperServer?znode=/test5?result=success
2016-12-28 14:17:10,613 | INFO  | CommitProcWorkThread-4 | session=0x12000007553b4903?
user=10.177.223.78,zkcli/hadoop.hadoop.com@HADOOP.COM?ip=10.177.223.78?operation=create znode?
target=ZooKeeperServer?znode=/test6?result=success
2016-12-28 14:17:10,633 | INFO  | CommitProcWorkThread-4 | session=0x12000007553b4903?
```

```
user=10.177.223.78,zkcli/hadoop.hadoop.com@HADOOP.COM?ip=10.177.223.78?operation=create znode?
target=ZooKeeperServer?znode=/test7?result=success
```

The content shows that logs of the ZooKeeper client user **zkcli/hadoop.hadoop.com@HADOOP.COM** are added to the audit log.

User details in ZooKeeper

In ZooKeeper, different authentication schemes use different credentials as users. Based on the authentication provider requirement, any parameter can be considered as users.

Example:

- **SAMLAuthenticationProvider** uses the client principal as a user.
- **X509AuthenticationProvider** uses the user client certificate as a user.
- **IAuthenticationProvider** uses the client IP address as a user.
- A username can be obtained from the custom authentication provider by implementing the **org.apache.zookeeper.server.auth.ExtAuthenticationProvider.getUserName(String)** method. If the method is not implemented, getting the username from the authentication provider instance will be skipped.

Enhanced Open Source Feature: ZooKeeper SSL Communication (Netty Connection)

The ZooKeeper design contains the Nio package and does not support SSL later than version 3.5. To solve this problem, Netty is added to ZooKeeper. Therefore, if you need to use SSL, enable Netty and set the following parameters on the server and client:

The open source server supports only plain text passwords, which may cause security problems. Therefore, such text passwords are no longer used on the server.

- Client
  a. Set **-Dzookeeper.client.secure** in the **zkCli.sh/zkEnv.sh** file to **true** to use secure communication on the client. Then, the client can connect to the secureClientPort on the server.
  b. Set the following parameters in the **zkCli.sh/zkEnv.sh** file to configure the client environment:

Parameter	Description
-Dzookeeper.clientCnxnSocket	Used for Netty communication between clients. Default value: **org.apache.zookeeper.ClientCnxnSocketNetty**
-Dzookeeper.ssl.keyStore.location	Indicates the path for storing the keystore file.
-Dzookeeper.ssl.keyStore.password	Encrypts a password.

Parameter	Description
-Dzookeeper.ssl.trustStore.location	Indicates the path for storing the truststore file.
-Dzookeeper.ssl.trustStore.password	Encrypts a password.
-Dzookeeper.config.crypt.class	Decrypts an encrypted password.
-Dzookeeper.ssl.password.encrypted	Default value: **false** If the keystore and truststore passwords are encrypted, set this parameter to **true**.
-Dzookeeper.ssl.enabled.protocols	Defines the SSL protocols to be enabled for the SSL context.
-Dzookeeper.ssl.exclude.cipher.ext	Defines the list of passwords separated by a comma which should be excluded from the SSL context.

NOTE

The preceding parameters must be set in the **zkCli.sh/zk.Env.sh** file.

- Server
  a. Set **secureClientPort** to **3381** in the **zoo.cfg** file.
  b. Set **zookeeper.serverCnxnFactory** to **org.apache.zookeeper.server.NettyServerCnxnFactory** in the **zoo.cfg** file on the server.
  c. Set the following parameters in the **zoo.cfg** file (in the **zookeeper/conf/zoo.cfg** path) to configure the server environment:

Parameter	Description
ssl.keyStore.location	Path for storing the **keystore.jks** file
ssl.keyStore.password	Encrypts a password.
ssl.trustStore.location	Indicates the path for storing the truststore file.
ssl.trustStore.password	Encrypts a password.
config.crypt.class	Decrypts an encrypted password.
ssl.keyStore.password.encrypted	Default value: **false** If this parameter is set to **true**, the encrypted password can be used.

Parameter	Description
ssl.trustStore.password.encrypted	Default value: **false** If this parameter is set to **true**, the encrypted password can be used.
ssl.enabled.protocols	Defines the SSL protocols to be enabled for the SSL context.
ssl.exclude.cipher.ext	Defines the list of passwords separated by a comma which should be excluded from the SSL context.

d. Start ZKserver and connect the security client to the security port.

- Credential

  The credential used between client and server in ZooKeeper is **X509AuthenticationProvider**. This credential is initialized using the server certificates specified and trusted by the following parameters:

  – zookeeper.ssl.keyStore.location
  – zookeeper.ssl.keyStore.password
  – zookeeper.ssl.trustStore.location
  – zookeeper.ssl.trustStore.password

  NOTE

  If you do not want to use default mechanism of ZooKeeper, then it can be configured with different trust mechanisms as needed.

1.4 Functions

1.4.1 Multi-tenant

Feature Introduction

Modern enterprises' data clusters are developing towards centralization and cloudification. Enterprise-class big data clusters must meet the following requirements:

- Carry data of different types and formats and run jobs and applications of different types (analysis, query, and stream processing).
- Isolate data of a user from that of another user who has demanding requirements on data security, such as a bank or government institute.

The preceding requirements bring the following challenges to the big data cluster:

- Proper allocation and scheduling of resources to ensure stable operating of applications and jobs
- Strict access control to ensure data and service security

Multi-tenant isolates the resources of a big data cluster into resource sets. Users can lease desired resource sets to run applications and jobs and store data. In a big data cluster, multiple resource sets can be deployed to meet diverse requirements of multiple users.

The MRS big data cluster provides a complete enterprise-class big data multi-tenant solution. Multi-tenant is a collection of multiple resources (each resource set is a tenant) in an MRS big data cluster. It can allocate and schedule resources, including computing and storage resources.

Advantages

- Proper resource configuration and isolation

  The resources of a tenant are isolated from those of another tenant. The resource use of a tenant does not affect other tenants. This mechanism ensures that each tenant can configure resources based on service requirements, improving resource utilization.

- Resource consumption measurement and statistics

  Tenants are system resource applicants and consumers. System resources are planned and allocated based on tenants. Resource consumption by tenants can be measured and recorded.

- Ensured data security and access security

  In multi-tenant scenarios, the data of each tenant is stored separately to ensure data security. The access to tenants' resources is controlled to ensure access security.

Enhanced Schedulers

Schedulers are divided into the open source Capacity scheduler and proprietary Superior scheduler.

To meet enterprise requirements and tackle challenges facing the Yarn community in scheduling, develops the Superior scheduler. In addition to inheriting the advantages of the Capacity scheduler and Fair scheduler, this scheduler is enhanced in the following aspects:

- Enhanced resource sharing policy

  The Superior scheduler supports queue hierarchy. It integrates the functions of open source schedulers and shares resources based on configurable policies. In terms of instances, MRS cluster administrators can use the Superior scheduler to configure an absolute value or percentage policy for queue resources. The resource sharing policy of the Superior scheduler enhances the label scheduling policy of Yarn as a resource pool feature. The nodes in the Yarn cluster can be grouped based on the capacity or service type to ensure that queues can more efficiently utilize resources.

- Tenant-based resource reservation policy

  Resources required by tenants must be ensured for running critical tasks. The Superior scheduler builds a mechanism to support the resource reservation policy. By doing so, reserved resources can be allocated to the tasks run by the tenant queues in a timely manner to ensure proper task execution.

- Fair sharing among tenants and resource pool users

The Superior scheduler allows shared resources to be configured for users in a queue. Each tenant may have users with different weights. Heavily weighted users may require more shared resources.

- Ensured scheduling performance in a big cluster

  The Superior scheduler receives heartbeats from each NodeManager and saves resource information in memory, which enables the scheduler to control cluster resource usage globally. The Superior scheduler uses the push scheduling model, which makes the scheduling more precise and efficient and remarkably improves cluster resource utilization. Additionally, the Superior scheduler delivers excellent performance when the interval between NodeManager heartbeats is long and prevents heartbeat storms in big clusters.

- Priority policy

  If the minimum resource requirement of a service cannot be met after the service obtains all available resources, a preemption occurs. The preemption function is disabled by default.

1.4.2 Security Hardening

MRS is a platform for massive data management and analysis and has high security. MRS protects user data and service running from the following aspects:

- Network isolation

  The entire system is deployed in a VPC on the cloud to provide an isolated network environment and ensure service and management security of the cluster. By combining the subnet division, route control, and security group functions of VPC, MRS provides a secure and reliable isolated network environment.

- Resource isolation

  MRS supports resource deployment and isolation of physical resources in dedicated zones. You can flexibly combine computing and storage resources, such as dedicated computing resources + shared storage resources, shared computing resources + dedicated storage resources, and dedicated computing resources + dedicated storage resources.

- Host security

  MRS can be integrated with security services, including Vulnerability Scan Service (VSS), Host Security Service (HSS), Web Application Firewall (WAF), Cloud Bastion Host (CBH), and Web Tamper Protection (WTP). The following measures are provided to improve security of the OS and ports:

  - Security hardening of OS kernels
  - OS patch update
  - OS permission control
  - OS port management
  - OS protocol and port attack defense

- Application security

  The following measures are used to ensure normal running of big data services:

  - Identification and authentication

  - Web application security
  - Access control
  - Audit security
  - Password security
- Data security

  The following measures are provided to ensure the confidentiality, integrity, and availability of massive amounts of user data:
  - Disaster recovery: MRS supports data backup to OBS and cross-region high reliability.
  - Backup: MRS supports backup of DBService, NameNode, and LDAP metadata and backup of HDFS and HBase service data.
- Data integrity

  Data is verified to ensure its integrity during storage and transmission.
  - CRC32C is used by default to verify the correctness of user data stored in HDFS.
  - DataNodes of HDFS store the verified data. If the data transmitted from a client is abnormal (incomplete), DataNodes report the abnormality to the client, and the client rewrites the data.
  - The client checks data integrity when reading data from a DataNode. If the data is incomplete, the client will read data from another DataNode.
- Data confidentiality

  Based on Apache Hadoop, the distributed file system of MRS supports encrypted storage of files to prevent sensitive data from being stored in plaintext, improving data security. Applications need only to encrypt specified sensitive data. Services are not affected during the encryption process. Based on file system data encryption, Hive provides table-level encryption and HBase provides column family-level encryption. Sensitive data can be encrypted and stored after you specify an encryption algorithm during table creation.

  Encrypted storage and access control of data are used to ensure user data security.
  - HBase stores service data to the HDFS after compression. Users can configure the AES and SMS4 encryption algorithm to encrypt data.
  - All the components allow access permissions to be set for local data directories. Unauthorized users are not allowed to access data.
  - All cluster user information is stored in ciphertext.
- Security authentication
  - Uses a unified user- and role-based authentication system as well as an account- and role-based access control (RBAC) model to centrally control user permissions and batch manage user authorization.
  - Employs Lightweight Directory Access Protocol (LDAP) as an account management system and performs the Kerberos authentication on accounts.
  - Provides the single sign-on (SSO) function that centrally manages and authenticates MRS system and component users.
  - Audits users who have logged in to Manager.

1.4.3 Easy Access to Web UIs of Components

Big data components have their own web UIs to manage their own systems. However, you cannot easily access the web UIs due to network isolation. For example, to access the HDFS web UI, you need to create an ECS to remotely log in to the web UI. This makes the UI access complex and unfriendly.

MRS provides an EIP-based secure channel for you to easily access the web UIs of components. This is more convenient than binding an EIP by yourself, and you can access the web UIs with a few clicks, avoiding the steps for logging in to a VPC, adding security group rules, and obtaining a public IP address. For the Hadoop, Spark, HBase, and Hue components in analysis clusters and the Storm component in streaming clusters, you can quickly access their web UIs from the entries on Manager.

1.4.4 Reliability Enhancement

Based on Apache Hadoop open source software, MRS optimizes and improves the reliability and performance of main service components.

System Reliability

- HA for all management nodes

  In the Hadoop open source version, data and compute nodes are managed in a distributed system, in which a single point of failure (SPOF) does not affect the operation of the entire system. However, a SPOF may occur on management nodes running in centralized mode, which becomes the weakness of the overall system reliability.

  MRS provides similar double-node mechanisms for all management nodes of the service components, such as Manager, HDFS NameNodes, HiveServers, HBase HMasters, Yarn ResourceManagers, KerberosServers, and LdapServers. All of them are deployed in active/standby mode or configured with load sharing, effectively preventing SPOFs from affecting system reliability.

- Reliability guarantee in case of exceptions

  By reliability analysis, the following measures to handle software and hardware exceptions are provided to improve the system reliability:

  - After power supply is restored, services are running properly regardless of a power failure of a single node or the whole cluster, ensuring data reliability in case of unexpected power failures. Key data will not be lost unless the hard disk is damaged.
  - Health status checks and fault handling of the hard disk do not affect services.
  - The file system faults can be automatically handled, and affected services can be automatically restored.
  - The process and node faults can be automatically handled, and affected services can be automatically restored.
  - The network faults can be automatically handled, and affected services can be automatically restored.

- Data backup and restoration

  MRS provides full backup, incremental backup, and restoration functions based on service requirements, preventing the impact of data loss and

damages on services and ensuring fast system restoration in case of exceptions.

- Automatic backup

  MRS provides automatic backup for data on Manager. Based on the customized backup policy, data on clusters, including LdapServer and DBService data, can be automatically backed up.

- Manual backup

  You can also manually back up data of the cluster management system before the capacity expansion and patch installation to recover the cluster management system functions upon faults.

  To improve the system reliability, data on Manager and HBase is backed up to a third-party server manually.

Node Reliability

- OS health status monitoring

  MRS periodically collects OS hardware resource usage data, including usage of CPUs, memory, hard disks, and network resources.

- Process health status monitoring

  MRS checks the status of service instances and health indicators of service instance processes, enabling you to know the health status of processes in a timely manner.

- Automatic disk troubleshooting

  MRS is enhanced based on the open source version. It can monitor the status of hardware and file systems on all nodes. If an exception occurs, the corresponding partitions will be removed from the storage pool. If a disk is faulty and replaced, a new hard disk will be added for running services. In this case, maintenance operations are simplified. Replacement of faulty disks can be completed online. In addition, users can set hot backup disks to reduce the faulty disk restoration time and improve the system reliability.

- LVM configuration for node disks

  MRS allows you to configure Logic Volume Management (LVM) to plan multiple disks as a logical volume group. Configuring LVM can avoid uneven usage of disks. It is especially important to ensure even usage of disks on components that can use multiple disk capabilities, such as HDFS and Kafka. In addition, LVM supports disk capacity expansion without re-attaching, preventing service interruption.

Data Reliability

MRS can use the anti-affinity node groups and placement group capabilities provided by ECS and the rack awareness capability of Hadoop to redundantly distribute data to multiple physical host machines, preventing data loss caused by physical hardware failures.

1.4.5 Job Management

The job management function provides an entry for you to submit jobs in a cluster, including MapReduce, Spark, HiveQL, and SparkSQL jobs. MRS works with DataArts Studio to provide a one-stop big data collaboration development

environment and fully-managed big data scheduling capabilities, helping you effortlessly build big data processing centers.

DataArts Studio allows you to develop and debug MRS HiveQL/SparkSQL scripts online and develop MRS jobs by performing drag-and-drop operations to migrate and integrate data between MRS and over 20 heterogeneous data sources. Powerful job scheduling and flexible monitoring and alarming help you easily manage data and job O&M.

1.4.6 Bootstrap Actions

Feature Introduction

MRS provides standard elastic big data clusters on the cloud. Nine big data components, such as Hadoop and Spark, can be installed and deployed. Currently, standard cloud big data clusters cannot meet all user requirements, for example, in the following scenarios:

- Common operating system configurations cannot meet data processing requirements, for example, increasing the maximum number of system connections.
- Software tools or running environments need to be installed, for example, Gradle and dependency R language package.
- Big data component packages need to be modified based on service requirements, for example, modifying the Hadoop or Spark installation package.
- Other big data components that are not supported by MRS need to be installed.

To meet the preceding customization requirements, you can manually perform operations on the existing and newly added nodes. The overall process is complex and error-prone. In addition, manual operations cannot be traced, and data cannot be processed immediately after creating a cluster based on your demand.

Therefore, MRS supports custom bootstrap actions that enable you to run scripts on a specified node before or after a cluster component is started. You can run bootstrap actions to install third-party software that is not supported by MRS, modify the cluster running environment, and perform other customizations. If you choose to run bootstrap actions when expanding a cluster, the bootstrap actions will be run on the newly added nodes in the same way. MRS runs the script you specify as user **root**. You can run the **su - *xxx*** command in the script to switch the user.

Customer Benefits

You can use the custom bootstrap actions to flexibly and easily configure your dedicated clusters and customize software installation.

1.4.7 Metadata

MRS provides multiple metadata storage methods. When deploying Hive during MRS cluster creation, select one of the following storage modes as required:

- **Local**: Metadata is stored in the local GaussDB of a cluster. When the cluster is deleted, the metadata is also deleted. To retain the metadata, manually back up the metadata in the database in advance.
- **Data Connection**: Metadata is stored in the associated PostgreSQL or MySQL database of the RDS service in the same VPC and subnet as the current cluster. When the cluster is terminated, the metadata is not deleted. Multiple MRS clusters can share the metadata.

1.4.8 Cluster Management

1.4.8.1 Cluster Lifecycle Management

MRS supports cluster lifecycle management, including creating and terminating clusters.

- Creating a cluster: After you specify a cluster type, components, number of nodes of each type, VM specifications, AZ, VPC, and authentication information, MRS automatically creates a cluster that meets the configuration requirements. You can run customized scripts in the cluster. In addition, you can create clusters of different types for multiple application scenarios, such as Hadoop analysis clusters, HBase clusters, and Kafka clusters. The big data platform supports heterogeneous cluster deployment. That is, VMs of different specifications can be combined in a cluster based on CPU types, disk capacities, disk types, and memory sizes. Various VM specifications can be mixed in a cluster.
- Terminating a cluster: You can terminate a cluster that is no longer needed (including data and configurations in the cluster). MRS will delete all resources related to the cluster.

Creating a Cluster

On the MRS management console, you can create an MRS cluster. You can select a region and cloud resource specifications to create an MRS cluster that is suitable for enterprise services with one click. MRS automatically installs and deploys the enterprise-level big data platform and optimizes parameters based on the selected cluster type, version, and node specifications.

MRS provides you with fully managed big data clusters. When creating a cluster, you can set a VM login mode (password or key pair). You can use all resources of the created MRS cluster. In addition, MRS allows you to deploy a big data cluster on only two ECSs with 4 vCPUs and 8 GB memory, providing more flexible choices for testing and development.

MRS clusters are classified into analysis, streaming, and hybrid clusters.

- Analysis cluster: is used for offline data analysis and provides Hadoop components.
- Streaming cluster: is used for streaming tasks and provides stream processing components.
- Hybrid cluster: is used for not only offline data analysis but also streaming processing, and provides Hadoop components and stream processing components.

- Custom: You can flexibly combine required components based on service requirements.

MRS cluster nodes are classified into Master, Core, and Task nodes.

- Master node: management node in a cluster. Master processes of a distributed system, Manager, and databases are deployed on Master nodes. Master nodes cannot be scaled out. The processing capability of Master nodes determines the upper limit of the management capability of the entire cluster. MRS supports scale-up of Master node specifications to provide support for management of a larger cluster.
- Core node: used for both storage and computing and can be scaled in or out. Since Core nodes bear data storage, there are many restrictions on scale-in to prevent data loss and auto scaling cannot be performed.
- Task node: used only for computing only and can be scaled in or out. Task nodes bear only computing tasks. Therefore, auto scaling can be performed.

You can create a cluster in two modes: custom creation and quick creation.

- Custom creation: On the **Custom Config** page, you can flexibly configure cluster parameters based on application scenarios, such as ECS specifications to better suit your service requirements.
- Quick creation: On the **Quick Config** page, you can quickly create a cluster based on application scenarios, improving cluster configuration efficiency. Currently, Hadoop analysis clusters, HBase clusters, and Kafka clusters are available for your quick creation.
  - Hadoop analysis cluster: uses components in the open-source Hadoop ecosystem to analyze and query vast amounts of data. For example, use Yarn to manage cluster resources, Hive and Spark to provide offline storage and computing of large-scale distributed data, Spark Streaming and Flink to offer streaming data computing, and Presto to enable interactive queries, and Tez to provide a distributed computing framework of directed acyclic graphs (DAGs).
  - HBase cluster: uses Hadoop and HBase components to provide a column-oriented distributed cloud storage system featuring enhanced reliability, excellent performance, and elastic scalability. It applies to the storage and distributed computing of massive amounts of data. You can use HBase to build a storage system capable of storing TB- or even PB-level data. With HBase, you can filter and analyze data with ease and get responses in milliseconds, rapidly mining data value.
  - Kafka cluster: uses Kafka and Storm to provide an open source message system with high throughput and scalability. It is widely used in scenarios such as log collection and monitoring data aggregation to implement efficient streaming data collection and real-time data processing and storage.

Terminating a Cluster

MRS allows you to terminate a cluster when it is no longer needed. After the cluster is terminated, all cloud resources used by the cluster will be released. Before terminating a cluster, you are advised to migrate or back up data. Terminate the cluster only when no service is running in the cluster or the cluster is abnormal and cannot provide services based on O&M analysis. If data is stored

on EVS disks or pass-through disks in a big data cluster, the data will be deleted after the cluster is terminated. Therefore, exercise caution when terminating a cluster.

1.4.8.2 Cluster Scaling

The processing capability of a big data cluster can be horizontally expanded by adding nodes. If the cluster scale does not meet service requirements, you can manually scale out or scale in the cluster. MRS intelligently selects the node with the least load or the minimum amount of data to be migrated for scale-in. The node to be scaled in will not receive new tasks, and continues to execute the existing tasks. At the same time, MRS copies its data to other nodes and the node is decommissioned. If the tasks on the node cannot be completed after a long time, MRS migrates the tasks to other nodes, minimizing the impact on cluster services.

Scaling Out a Cluster

Currently, you can add Core or Task nodes to scale out a cluster to handle peak service loads. Adding MRS cluster nodes does not affect the services of the existing cluster.

Scaling In a Cluster

You can reduce the number of Core or Task nodes to scale in a cluster so that MRS delivers better storage and computing capabilities at lower O&M costs based on service requirements. After you scale in an MRS cluster, MRS automatically selects nodes that can be scaled in based on the type of services installed on the nodes.

During the scale-in of Core nodes, data on the original nodes is migrated. If the data location is cached, the client automatically updates the location information, which may affect the latency. Node scale-in may affect the response duration of the first access to some HBase on HDFS data. You can restart HBase or disable or enable related tables to avoid this problem.

Task nodes do not store cluster data. They are compute nodes and do not involve migration of data on the nodes.

1.4.8.3 Auto Scaling

Feature Introduction

More and more enterprises use technologies such as Spark and Hive to analyze data. Processing a large amount of data consumes huge resources and costs much. Typically, enterprises regularly analyze data in a fixed period of time every day rather than all day long. To meet enterprises' requirements, MRS provides the auto scaling function to apply for extra resources during peak hours and release resources during off-peak hours. This enables users to use resources on demand and focus on core business at lower costs.

In big data applications, especially in periodic data analysis and processing scenarios, cluster computing resources need to be dynamically adjusted based on service data changes to meet service requirements. The auto scaling function of MRS enables clusters to be elastically scaled out or in based on cluster loads. In

addition, if the data volume changes regularly and you want to scale out or in a cluster before the data volume changes, you can use the MRS resource plan feature.

MRS supports two types of auto scaling policies: auto scaling rules and resource plans

- Auto scaling rules: You can increase or decrease Task nodes based on real-time cluster loads. Auto scaling will be triggered when the data volume changes but there may be some delay.
- Resource plans: If the data volume changes periodically, you can create resource plans to resize the cluster before the data volume changes, thereby avoiding a delay in increasing or decreasing resources.

Both auto scaling rules and resource plans can trigger auto scaling. You can configure both of them or configure one of them. Configuring both resource plans and auto scaling rules improves the cluster node scalability to cope with occasionally unexpected data volume peaks.

In some service scenarios, resources need to be reallocated or service logic needs to be modified after cluster scale-out or scale-in. If you manually scale out or scale in a cluster, you can log in to cluster nodes to reallocate resources or modify service logic. If you use auto scaling, MRS enables you to customize automation scripts for resource reallocation and service logic modification. Automation scripts can be executed before and after auto scaling and automatically adapt to service load changes, all of which eliminates manual operations. In addition, automation scripts can be fully customized and executed at various moments, which can meet your personalized requirements and improve auto scaling flexibility.

Customer Benefits

MRS auto scaling provides the following benefits:

- Reducing costs

  Enterprises do not analyze data all the time but perform a batch data analysis in a specified period of time, for example, 03:00 a.m. The batch analysis may take only two hours.

  The auto scaling function enables enterprises to add nodes for batch analysis and automatically releases the nodes after completion of the analysis, minimizing costs.

- Meeting instant query requirements

  Enterprises usually encounter instant analysis tasks, for example, data reports for supporting enterprise decision-making. As a result, resource consumption increases sharply in a short period of time. With the auto scaling function, compute nodes can be added for emergent big data analysis, avoiding a service breakdown due to insufficient compute resources. In this way, you do not need to create extra resources. After the emergency ends, MRS automatically releases the nodes.

- Focusing on core business

  It is difficult for developers to determine resource consumption on the big data secondary development platform because of complex query analysis conditions (such as global sorting, filtering, and merging) and data complexity, for example, uncertainty of incremental data. As a result,

estimating the computing volume is difficult. MRS's auto scaling function enable developers to focus on service development without the need for resource estimation.

1.4.8.4 Task Node Creation

Feature Introduction

Task nodes can be created and used for computing only. They do not store persistent data and are the basis for implementing auto scaling.

Customer Benefits

When MRS is used only as a computing resource, Task nodes can be used to reduce costs and facilitate cluster node scaling, flexibly meeting users' requirements for increasing or decreasing cluster computing capabilities.

Application Scenarios

When the data volume change is small in a cluster but the cluster's service processing capabilities need to be remarkably and temporarily improved, add Task nodes to address the following situations:

- The number of temporary services is increased, for example, report processing at the end of the year.
- Long-term tasks need to be completed in a short time, for example, some urgent analysis tasks.

1.4.8.5 Isolating a Host

When detecting that a host is abnormal or faulty and cannot provide services or affects cluster performance, you can exclude the host from the available nodes in the cluster temporarily so that the client can access other available nodes. In scenarios where patches are to be installed in a cluster, you can also exclude a specified node from patch installation. Only non-management nodes can be isolated.

After a host is isolated, all role instances on the host will be stopped, and you cannot start, stop, or configure the host and all instances on the host. In addition, after a host is isolated, statistics about the monitoring status and metric data of hardware and instances on the host cannot be collected or displayed.

1.4.8.6 Managing Tags

Tags are cluster identifiers. Adding tags to clusters can help you identify and manage your cluster resources. By associating with Tag Management Service (TMS), MRS allows users with a large number of cloud resources to tag cloud resources, quickly search for cloud resources with the same tag attribute, and perform unified management operations such as review, modification, and deletion, facilitating unified management of big data clusters and other cloud resources.

You can add a maximum of 10 tags to a cluster when creating the cluster or add them on the details page of the created cluster.

1.4.9 Cluster O&M

Alarm Management

MRS can monitor big data clusters in real time and identify system health status based on alarms and events. In addition, MRS allows you to customize monitoring and alarm thresholds to focus on the health status of each metric. When monitoring data reaches the alarm threshold, the system triggers an alarm.

MRS can also interconnect with the message service system of the Simple Message Notification (SMN) service to push alarm information to users by SMS message or email. For details, see **Message Notification**.

O&M Support

Cluster resources provided by MRS belong to users. Generally, when O&M personnel's support is required for troubleshooting of a cluster, O&M personnel cannot directly access the cluster. To better serve customers, MRS provides the following two methods to improve communication efficiency during fault locating:

- Log sharing: You can initiate log sharing on the MRS management console to share a specified log scope with O&M personnel, so that O&M personnel can locate faults without accessing the cluster.
- O&M authorization: If a problem occurs when you use an MRS cluster, you can initiate O&M authorization on the MRS management console. O&M personnel can help you quickly locate the problem, and you can revoke the authorization at any time.

Health Check

MRS provides automatic inspection on system running environments for you to check and audit system running health status in one click, ensuring proper system running and lowering system operation and maintenance costs. After viewing inspection results, you can export reports for archiving and fault analysis.

1.4.10 Message Notification

Feature Introduction

The following operations are often performed during the running of a big data cluster:

- Big data clusters often change, for example, cluster scale-out and scale-in.
- When a service data volume changes abruptly, auto scaling will be triggered.
- After related services are stopped, a big data cluster needs to be stopped.

To immediately notify you of successful operations, cluster unavailability, and node faults, MRS uses Simple Message Notification (SMN) to send notifications to you through SMS and emails, facilitating maintenance.

Customer Benefits

After configuring SMN, you can receive MRS cluster health status, updates, and component alarms through SMS or emails in real time. MRS sends real-time

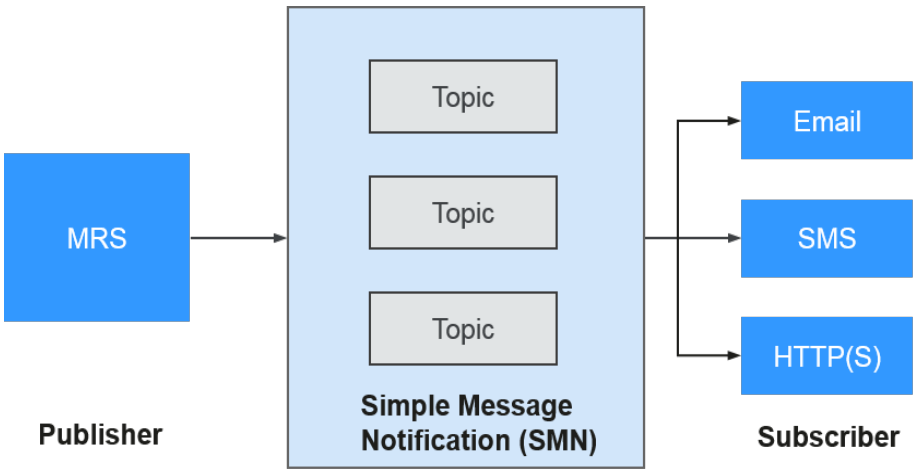
monitoring and alarm notification to help you easily perform O&M and efficiently deploy big data services.

Feature Description

MRS uses SMN to provide one-to-multiple message subscription and notification over a variety of protocols.

You can create a topic and configure topic policies to control publisher and subscriber permissions on the topic. MRS sends cluster messages to the topic to which you have permission to publish messages. Then, all subscribers who subscribe to the topic can receive cluster updates and component alarms through SMS and emails.

Figure 1-127 Implementation process



1.5 Constraints

Before using MRS, ensure that you have read and understand the following restrictions.

- MRS clusters must be created in VPC subnets.
- You are advised to use any of the following browsers to access MRS:
  - Google Chrome: 36.0 or later
  - Internet Explorer: 9.0 or later
- When you create an MRS cluster, you can select **Auto create** from the drop-down list of **Security Group** to create a security group or select an existing security group. After the MRS cluster is created, do not delete or modify the used security group. Otherwise, a cluster exception may occur.
- To prevent illegal access, only assign access permission for security groups used by MRS where necessary.
- Do not perform the following operations because they will cause cluster exceptions:
  - Shutting down, restarting, or deleting MRS cluster nodes displayed in ECS, changing or reinstalling their OS, or modifying their specifications.

  - Deleting the existing processes, applications or files on cluster nodes.
- If a cluster exception occurs when no incorrect operations have been performed, contact technical support engineers. They will ask you for your and then perform troubleshooting.
- Plan disks of cluster nodes based on service requirements. If you want to store a large volume of service data, add EVS disks or storage space to prevent insufficient storage space from affecting node running.
- The cluster nodes store only users' service data. Non-service data can be stored in the OBS or other ECS nodes.
- The cluster nodes only run MRS cluster programs. Other client applications or user service programs are deployed on separate ECS nodes.
- To expand the storage capacity of nodes (including master, core, and task) in an MRS cluster, create new disks and then attach them to the nodes.
- The capacity (including storage and computing capabilities) of an MRS cluster can be expanded by adding core or task nodes.
- If the cluster is still used to execute tasks or modify configurations after a master node in the cluster is stopped, and other master nodes in the cluster are stopped before the stopped master node is started after task execution or configuration modification, data may be lost due to an active/standby switchover. In this scenario, after the task is executed or the configuration is modified, start the master node that has been stopped and then stop all nodes. If all nodes in the cluster have been stopped, start them in the reverse order of node shutdown.
- The Capacity and Superior scheduler switchover is complete when the MRS cluster is used, while configuration synchronization is not complete. Configure synchronization again based on the new scheduler if necessary.

1.6 Permissions Management

If you need to assign different permissions to employees in your enterprise to access your MRS resources on the cloud, IAM is a good choice for fine-grained permissions management. IAM provides identity authentication, permissions management, and access control, helping you secure access to your cloud resources.

With IAM, you can create IAM users under your cloud account, and assign permissions to these users to control their access to specific resources. For example, some software developers in your enterprise need to use MRS resources but must not delete MRS clusters or perform any high-risk operations. To achieve this goal, you can create IAM users for the software developers and grant them only the permissions required for using MRS cluster resources.

If your cloud account does not require individual IAM users for permissions management, skip this section.

IAM is free of charge.

MRS Permission Description

By default, new IAM users do not have any permissions. To assign permissions to a user, add the user to one or more groups and assign permissions policies or roles

to these groups. The user then inherits permissions from the groups it is a member of and can perform specified operations on cloud services based on the permissions.

MRS is a project-level service deployed and accessed in specific physical regions. To assign permissions to a user group, specify **Scope** as **Region-specific projects** and select projects in the corresponding region for the permissions to take effect. If **All projects** is selected, the permissions will take effect for the user group in all region-specific projects. When accessing MRS, the users need to switch to a region where they have been authorized to use the MRS service.

You can grant users permissions by using roles and policies.

- Roles: A type of coarse-grained authorization mechanism that defines permissions related to user responsibilities. This mechanism provides only a limited number of service-level roles for authorization. When using roles to grant permissions, you need to also assign other roles on which the permissions depend to take effect. However, roles are not an ideal choice for fine-grained authorization and secure access control.
- Policies: A type of fine-grained authorization mechanism that defines permissions required to perform operations on specific cloud resources under certain conditions. This mechanism allows for more flexible policy-based authorization, meeting requirements for secure access control. For example, you can grant MRS users only the permissions for performing specified operations on MRS clusters, such as creating a cluster and querying a cluster list rather than deleting a cluster. Most policies define permissions based on APIs.

Table 1-27 lists all the system policies supported by MRS.

Table 1-27 MRS system policies

Policy	Description	Type
MRS FullAccess	Administrator permissions for MRS. Users granted these permissions can operate and use all MRS resources.	Fine-grained policy
MRS CommonOperations	Common user permissions for MRS. Users granted these permissions can use MRS but cannot add or delete resources.	Fine-grained policy
MRS ReadOnlyAccess	Read-only permission for MRS. Users granted these permissions can only view MRS resources.	Fine-grained policy
MRS Administrator	Permissions: • All operations on MRS • Users with permissions of this policy must also be granted permissions of the **Tenant Guest** and **Server Administrator** policies.	RBAC policy

Table 1-28 lists the common operations supported by each system-defined policy or role of MRS. Select the policies or roles as required.

Table 1-28 Common operations supported by each system-defined policy

Operation	MRS FullAccess	MRS CommonOperations	MRS ReadOnlyAccess	MRS Administrator
Creating a cluster	√	x	x	√

1.7 Related Services

Relationships with Other Services

Table 1-29 Relationships with other services

Service	Relationships
Virtual Private Cloud (VPC)	MRS clusters are created in the subnets of a VPC. VPCs provide a secure, isolated, and logical network environment for your MRS clusters.
Object Storage Service (OBS)	OBS stores the following user data: • MRS job input data, such as user programs and data files • MRS job output data, such as result files and log files of jobs In MRS clusters, HDFS, Hive, MapReduce, YARN, Spark, Flume, and Loader can import or export data from OBS. MRS uses the parallel file system of OBS to provide services.
Elastic Cloud Server (ECS)	MRS uses elastic cloud servers (ECSs) as cluster nodes.
Relational Database Service (RDS)	RDS stores MRS system running data, including MRS cluster metadata.
Identity and Access Management (IAM)	IAM provides authentication for MRS.
Simple Message Notification (SMN)	MRS uses SMN to provide one-to-multiple message subscription and notification over a variety of protocols.
Cloud Trace Service (CTS)	CTS provides you with operation records of MRS resource operation requests and request results for querying, auditing, and backtracking.

Table 1-30 MRS operations recorded by CTS

Operation	Resource Type	Trace Name
Creating a cluster	cluster_mrs	createCluster
Deleting a cluster	cluster_mrs	deleteCluster
Expanding a cluster	cluster_mrs	scaleOutCluster
Shrinking a cluster	cluster_mrs	scaleInCluster

After you enable CTS, the system starts recording operations on cloud resources. You can view operation records of the last 7 days on the CTS management

console. For details, see **Cloud Trace Service** > **Getting Started** > **Querying Real-Time Traces**.

2 Preparing a User

2.1 Creating an MRS User

Use IAM to implement fine-grained permission control over your MRS. With IAM, you can:

- Create IAM users under your cloud account for employees based on your enterprise's organizational structure so that each employee is allowed to access MRS resources using their unique security credential (IAM user).
- Grant only the permissions required for users to perform a specific task.
- Entrust a cloud account or cloud service to perform efficient O&M on your MRS resources.

If your cloud account does not require IAM users, skip this section.

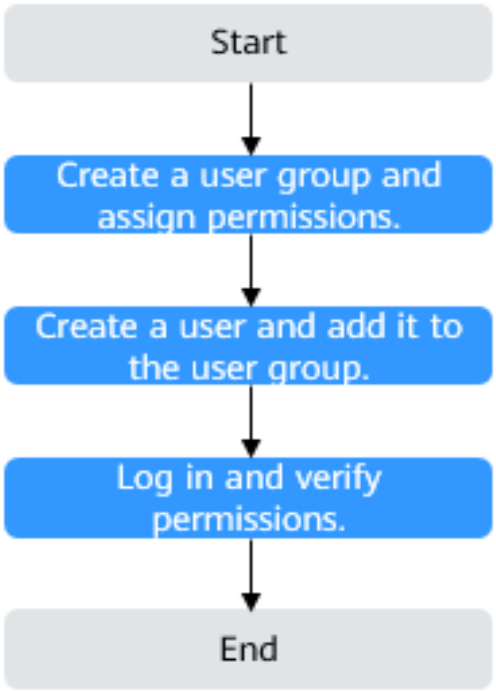
This section describes the procedure for granting permissions (see **Figure 2-1**).

Prerequisites

Learn about the permissions.

Process Flow

Figure 2-1 Process for granting MRS permissions



1. Create a user group on the IAM console, and assign MRS permissions to the group.
2. .

   Create a user on the IAM console and add the user to the group created in **1. Create a user group and assign permissions to it**.
3. Log in and verify permissions.

   Log in to the console by using the user created, and verify that the user has the granted permissions.

   - Choose **Service List** > **Analytics** > **MapReduce Service**. Click **Create Cluster** on the MRS console. If you fail to create an MRS cluster (assume that you only have the **MRS ReadOnlyAccess** permission), the **MRS ReadOnlyAccess** policy has taken effect.
   - Choose any other service in **Service List**. If a message appears indicating that you have insufficient permissions to access the service, the **MRS ReadOnlyAccess** policy has already taken effect.

MRS Permission Description

By default, new IAM users do not have any permissions. To assign permissions to a user, add the user to one or more groups and assign permissions policies or roles to these groups. The user then inherits permissions from the groups it is a member of and can perform specified operations on cloud services based on the permissions.

MRS is a project-level service deployed and accessed in specific physical regions. To assign permissions to a user group, specify **Scope** as **Region-specific projects** and select projects in the corresponding region for the permissions to take effect. If **All projects** is selected, the permissions will take effect for the user group in all region-specific projects. When accessing MRS, the users need to switch to a region where they have been authorized to use the MRS service.

You can grant permissions by using roles and policies.

- Roles: A type of coarse-grained authorization mechanism that defines permissions related to user responsibilities. This mechanism provides only a limited number of service-level roles for authorization. When using roles to grant permissions, you need to also assign other roles on which the permissions depend to take effect. However, roles are not an ideal choice for fine-grained authorization and secure access control.
- Policies: A type of fine-grained authorization mechanism that defines permissions required to perform operations on specific cloud resources under certain conditions. This mechanism allows for more flexible policy-based authorization, meeting requirements for secure access control. For example, you can grant MRS users only the permissions for performing specified operations on MRS clusters, such as creating a cluster and querying a cluster list rather than deleting a cluster. Most policies define permissions based on APIs.

Table 2-1 lists all the default system policies supported by MRS.

Table 2-1 MRS system policies

Policy	Description	Type
MRS FullAccess	Administrator permissions for MRS. Users granted these permissions can operate and use all MRS resources.	Fine-grained policy
MRS CommonOperations	Common user permissions for MRS. Users granted these permissions can use MRS but cannot add or delete resources.	Fine-grained policy
MRS ReadOnlyAccess	Read-only permission for MRS. Users granted these permissions can only view MRS resources.	Fine-grained policy
MRS Administrator	Permissions: • All operations on MRS • Users with permissions of this policy must also be granted permissions of the **Tenant Guest** and **Server Administrator** policies.	RBAC policy

Table 2-2 lists the common operations supported by each system-defined policy or role of MRS. Select the policies or roles as required.

Table 2-2 Common operations supported by each system-defined policy

Operation	MRS FullAccess	MRS CommonOperations	MRS ReadOnlyAccess	MRS Administrator
Creating a cluster	√	x	x	√
Resizing a cluster	√	x	x	√
Upgrading node specifications	√	x	x	√
Deleting a cluster	√	x	x	√
Querying cluster details	√	√	√	√
Querying a cluster list	√	√	√	√
Configuring an auto scaling rule	√	x	x	√
Querying a host list	√	√	√	√
Querying operation logs	√	√	√	√
Creating and executing a job	√	√	x	√
Stopping a job	√	√	x	√
Deleting a single job	√	√	x	√
Deleting jobs in batches	√	√	x	√
Querying job details	√	√	√	√

Operation	MRS FullAccess	MRS CommonOperations	MRS ReadOnlyAccess	MRS Administrator
Querying a job list	√	√	√	√
Creating a folder	√	√	x	√
Deleting a file	√	√	x	√
Querying a file list	√	√	√	√
Operating cluster tags in batches	√	√	x	√
Creating a single cluster tag	√	√	x	√
Deleting a single cluster tag	√	√	x	√
Querying a resource list by tag	√	√	√	√
Querying cluster tags	√	√	√	√
Accessing Manager	√	√	x	√
Querying a patch list	√	√	√	√
Installing a patch	√	√	x	√
Uninstalling a patch	√	√	x	√
Authorizing O&M channels	√	√	x	√
Sharing O&M channel logs	√	√	x	√

Operation	MRS FullAccess	MRS CommonOperations	MRS ReadOnlyAccess	MRS Administrator
Querying an alarm list	√	√	√	√
Subscribing to alarm notification	√	√	x	√
Submitting an SQL statement	√	√	x	√
Querying SQL results	√	√	x	√
Canceling an SQL execution task	√	√	x	√

2.2 Creating a Custom Policy

Custom policies can be created to supplement the system-defined policies of MRS. For the actions that can be added to custom policies, see **Permissions Policies and Supported Actions** > **Introduction** in MapReduce Service API Reference.

You can create custom policies in either of the following ways:

- Visual editor: Select cloud services, actions, resources, and request conditions. This does not require knowledge of policy syntax.
- JSON: Edit JSON policies from scratch or based on an existing policy.

NOTE

Custom policy modifications do not take effect immediately. You need to wait about 15 minutes.

The following section contains examples of common MRS custom policies.

Example Custom Policies

- Example 1: Allowing users to create MRS clusters only

```
{
    "Version": "1.1",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "mrs:cluster:create",
                "ecs:*:*",
```

```
            "bms:*:*",
            "evs:*:*",
            "vpc:*:*",
            "smn:*:*"
        ]
    }
  ]
}
```

- Example 2: Allowing users to resize an MRS cluster

```
{
  "Version": "1.1",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "mrs:cluster:resize"
      ]
    }
  ]
}
```

- Example 3: Allowing users to create a cluster, create and execute a job, and delete a single job, but denying cluster deletion

```
{
  "Version": "1.1",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "mrs:cluster:create",
        "mrs:job:submit",
        "mrs:job:delete"
      ]
    },
    {
      "Effect": "Deny",
      "Action": [
        "mrs:cluster:delete"
      ]
    }
  ]
}
```

- Example 4: Allowing users to create an ECS cluster with the minimum permission

  NOTE

  - If you need a key pair when creating a cluster, add the following permissions: **ecs:serverKeypairs:get** and **ecs:serverKeypairs:list**.
  - Add the **kms:cmk:list** permission when encrypting data disks during cluster creation.
  - Add the **mrs:alarm:subscribe** permission to enable the alarm function during cluster creation.
  - Add the **rds:instance:list** permission to use external data sources during cluster creation.

```
{
  "Version": "1.1",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "mrs:cluster:create"
      ]
    },
    {
```

```
            "Effect": "Allow",
            "Action": [
                "ecs:cloudServers:updateMetadata",
                "ecs:cloudServerFlavors:get",
                "ecs:cloudServerQuotas:get",
                "ecs:servers:list",
                "ecs:servers:get",
                "ecs:cloudServers:delete",
                "ecs:cloudServers:list",
                "ecs:serverInterfaces:get",
                "ecs:serverGroups:manage",
                "ecs:servers:setMetadata",
                "ecs:cloudServers:get",
                "ecs:cloudServers:create"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "vpc:securityGroups:create",
                "vpc:securityGroupRules:delete",
                "vpc:vpcs:create",
                "vpc:ports:create",
                "vpc:securityGroups:get",
                "vpc:subnets:create",
                "vpc:privateIps:delete",
                "vpc:quotas:list",
                "vpc:networks:get",
                "vpc:publicIps:list",
                "vpc:securityGroups:delete",
                "vpc:securityGroupRules:create",
                "vpc:privateIps:create",
                "vpc:ports:get",
                "vpc:ports:delete",
                "vpc:publicIps:update",
                "vpc:subnets:get",
                "vpc:publicIps:get",
                "vpc:ports:update",
                "vpc:vpcs:list"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "evs:quotas:get",
                "evs:types:get"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "bms:serverFlavors:get"
            ]
        }
    ]
}
```

- Example 5: Allowing users to create a BMS cluster with the minimum permission

NOTE

- If you need a key pair when creating a cluster, add the following permissions: **ecs:serverKeypairs:get** and **ecs:serverKeypairs:list**.
- Add the **kms:cmk:list** permission when encrypting data disks during cluster creation.
- Add the **mrs:alarm:subscribe** permission to enable the alarm function during cluster creation.
- Add the **rds:instance:list** permission to use external data sources during cluster creation.

```
{
  "Version": "1.1",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "mrs:cluster:create"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "ecs:servers:list",
        "ecs:servers:get",
        "ecs:cloudServers:delete",
        "ecs:serverInterfaces:get",
        "ecs:serverGroups:manage",
        "ecs:servers:setMetadata",
        "ecs:cloudServers:create",
        "ecs:cloudServerFlavors:get",
        "ecs:cloudServerQuotas:get"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "vpc:securityGroups:create",
        "vpc:securityGroupRules:delete",
        "vpc:vpcs:create",
        "vpc:ports:create",
        "vpc:securityGroups:get",
        "vpc:subnets:create",
        "vpc:privateIps:delete",
        "vpc:quotas:list",
        "vpc:networks:get",
        "vpc:publicIps:list",
        "vpc:securityGroups:delete",
        "vpc:securityGroupRules:create",
        "vpc:privateIps:create",
        "vpc:ports:get",
        "vpc:ports:delete",
        "vpc:publicIps:update",
        "vpc:subnets:get",
        "vpc:publicIps:get",
        "vpc:ports:update",
        "vpc:vpcs:list"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "evs:quotas:get",
        "evs:types:get"
      ]
    },
    {
      "Effect": "Allow",
```

```
            "Action": [
                "bms:servers:get",
                "bms:servers:list",
                "bms:serverQuotas:get",
                "bms:servers:updateMetadata",
                "bms:serverFlavors:get"
            ]
        }
    ]
}
```

- Example 6: Allowing users to create a hybrid ECS and BMS cluster with the minimum permission

  NOTE

  - If you need a key pair when creating a cluster, add the following permissions: **ecs:serverKeypairs:get** and **ecs:serverKeypairs:list**.
  - Add the **kms:cmk:list** permission when encrypting data disks during cluster creation.
  - Add the **mrs:alarm:subscribe** permission to enable the alarm function during cluster creation.
  - Add the **rds:instance:list** permission to use external data sources during cluster creation.

```
{
    "Version": "1.1",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "mrs:cluster:create"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "ecs:cloudServers:updateMetadata",
                "ecs:cloudServerFlavors:get",
                "ecs:cloudServerQuotas:get",
                "ecs:servers:list",
                "ecs:servers:get",
                "ecs:cloudServers:delete",
                "ecs:cloudServers:list",
                "ecs:serverInterfaces:get",
                "ecs:serverGroups:manage",
                "ecs:servers:setMetadata",
                "ecs:cloudServers:get",
                "ecs:cloudServers:create"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "vpc:securityGroups:create",
                "vpc:securityGroupRules:delete",
                "vpc:vpcs:create",
                "vpc:ports:create",
                "vpc:securityGroups:get",
                "vpc:subnets:create",
                "vpc:privateIps:delete",
                "vpc:quotas:list",
                "vpc:networks:get",
                "vpc:publicIps:list",
                "vpc:securityGroups:delete",
                "vpc:securityGroupRules:create",
                "vpc:privateIps:create",
                "vpc:ports:get",
```

```
                "vpc:ports:delete",
                "vpc:publicIps:update",
                "vpc:subnets:get",
                "vpc:publicIps:get",
                "vpc:ports:update",
                "vpc:vpcs:list"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "evs:quotas:get",
                "evs:types:get"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "bms:servers:get",
                "bms:servers:list",
                "bms:serverQuotas:get",
                "bms:servers:updateMetadata",
                "bms:serverFlavors:get"
            ]
        }
    ]
}
```

2.3 Synchronizing IAM Users to MRS

IAM user synchronization is to synchronize IAM users bound with MRS policies to the MRS system and create accounts with the same usernames but different passwords as the IAM users. Then, you can use an IAM username (the password needs to be reset by user **admin** of Manager) to log in to Manager for cluster management, and submit jobs on the GUI in a cluster with Kerberos authentication enabled.

Table 2-3 compares IAM users' permission policies and the synchronized users' permissions on MRS. For details about the default permissions on Manager, see **Default Permission Information**.

Table 2-3 Policy and permission mapping after synchronization

Policy Type	IAM Policy	User's Default Permissions on MRS After Synchronization	Have Permission to Perform the Synchronization	Have Permission to Submit Jobs
Fine-grained	MRS ReadOnlyAccess	Manager_viewer	No	No

Policy Type	IAM Policy	User's Default Permissions on MRS After Synchronization	Have Permission to Perform the Synchronization	Have Permission to Submit Jobs
	MRS CommonOperations	• Manager_viewer • default • launcher-job	No	Yes
	MRS FullAccess	• Manager_administrator • Manager_auditor • Manager_operator • Manager_tenant • Manager_viewer • System_administrator • default • launcher-job	Yes	Yes
RBAC	MRS Administrator	• Manager_administrator • Manager_auditor • Manager_operator • Manager_tenant • Manager_viewer • System_administrator • default • launcher-job	No	Yes

Policy Type	IAM Policy	User's Default Permissions on MRS After Synchronization	Have Permission to Perform the Synchronization	Have Permission to Submit Jobs
	Server Administrator, Tenant Guest, and MRS Administrator	• Manager_administrator • Manager_auditor • Manager_operator • Manager_tenant • Manager_viewer • System_administrator • default • launcher-job	Yes	Yes
	Tenant Administrator	• Manager_administrator • Manager_auditor • Manager_operator • Manager_tenant • Manager_viewer • System_administrator • default • launcher-job	Yes	Yes

Policy Type	IAM Policy	User's Default Permissions on MRS After Synchronization	Have Permission to Perform the Synchronization	Have Permission to Submit Jobs
Custom	Custom policy	• Manager_viewer • default • launcher-job	• If custom policies use RBAC policies as a template, refer to the RBAC policies. • If custom policies use fine-grained policies as a template, refer to the fine-grained policies. The fine-grained policies are recommended.	Yes

NOTE

To facilitate user permission management, use fine-grained policies rather than RBAC policies. In fine-grained policies, the Deny action takes precedence over other actions.

- A user has permission to synchronize IAM users only when the user has the Tenant Administrator role or has the Server Administrator, Tenant Guest, and MRS Administrator roles at the same time.
- A user with the **action:mrs:cluster:syncUser** policy has permission to synchronize IAM users.

Procedure

Step 1 Create a user and authorize the user to use MRS. For details, see **Creating an MRS User**.

Step 2 Log in to the MRS management console and create a cluster. For details, see **Creating a Custom Cluster**.

Step 3 In the left navigation pane, choose **Clusters** > **Active Clusters**. Click the cluster name to go to the cluster details page.

Step 4 On the **Dashboard** tab page, click **Synchronize** next to **IAM User Sync** to synchronize IAM users.

Step 5 In the **IAM User Sync** dialog box, search for the user group to which the IAM user to be synchronized belongs and click the user group name. In the **User** column, select the desired IAM user and click **Synchronize**.

NOTE

- You can select all users to synchronize them at a time.
- If you select user groups only, users will not be synchronized. You must select specific user names in the user group.
- All user groups are displayed. Those cannot be selected cannot be synchronized.

Step 6 After a synchronization request is sent, choose **Operation Logs** in the navigation tree on the left of the MRS console to check whether the synchronization is successful. For details about the logs, see **Viewing MRS Operation Logs**.

Step 7 After the synchronization is successful, use the user synchronized with IAM to perform subsequent operations.

NOTE

- When the policy of the user group to which the IAM user belongs changes from **MRS ReadOnlyAccess** to **MRS CommonOperations**, **MRS FullAccess**, or **MRS Administrator**, wait for 5 minutes until the new policy takes effect after the synchronization is complete because the **SSSD** (System Security Services Daemon) cache of cluster nodes needs time to be updated. Then, submit a job. Otherwise, the job may fail to be submitted.
- When the policy of the user group to which the IAM user belongs changes from **MRS CommonOperations**, **MRS FullAccess**, or **MRS Administrator** to **MRS ReadOnlyAccess**, wait for 5 minutes until the new policy takes effect after the synchronization is complete because the **SSSD** cache of cluster nodes needs time to be updated.
- After you click **Synchronize** on the right side of **IAM User Sync**, the cluster details page is blank for a short time, because user data is being synchronized. The page will be properly displayed after the data synchronization is complete.

- Submitting jobs in a security cluster: Users can submit jobs using the job management function on the GUI in the security cluster. For details, see **Running a MapReduce Job**.
- All tabs are displayed on the cluster details page, including **Components**, **Tenants**, and **Backups & Restorations**.
- Logging in to Manager
  a. Log in to Manager as user **admin**. For details, see **Accessing FusionInsight Manager**.
  b. Initialize the password of the user synchronized with IAM.
  c. Modify the role bound to the user group to which the user belongs to control user permissions on Manager. After the component role bound to the user group to which the user belongs is modified, it takes some time for the role permissions to take effect.
  d. Log in to Manager using the user synchronized with IAM and the password after the initialization in **Step 7.b**.

> **NOTE**
>
> If the IAM user's permission changes, go to **Step 4** to perform second synchronization. After the second synchronization, a system user's permissions are the union of the permissions defined in the IAM system policy and the permissions of roles added by the system user on Manager. After the second synchronization, a custom user's permissions are subject to the permissions configured on Manager.
>
> - System user: If all user groups to which an IAM user belongs are bound to system policies (RABC policies and fine-grained policies belong to system policies), the IAM user is a system user.
> - Custom user: If the user group to which an IAM user belongs is bound to any custom policy, the IAM user is a custom user.

Step 8 Undo IAM user synchronization.

To undo the synchronization of an IAM user, select the user in the **User** column in the **Synchronized** tab and click **Undo Sync**.

To undo the synchronization of all users in an IAM user group, select the user group in the **User Group** column in the **Synchronized** tab and click **Undo Sync**.

----End

3 Getting Started

3.1 How to Use MRS

MapReducce Service is a cloud service that is used to deploy and manage Hadoop clusters. MRS provides enterprise-class big data clusters on the cloud. Tenants can fully control these clusters and easily run big data components such as Hadoop, Spark, HBase, and Kafka in them.

MRS is easy to use. You can execute various tasks and process or store PB-level data using computers connected in a cluster.

The procedure of using MRS is as follows:

1. On the MRS console, create clusters and specify these clusters for offline data analysis and stream processing, and specify the Elastic Cloud Server (ECS) instance specifications, quantity, data disk types (common I/O, high I/O, or ultra-high I/O), as well as components to be installed in the clusters.
2. Upload the prepared program and data files to Object Storage Service (OBS) or the HDFS in the cluster.
3. After a cluster is created, you can directly add jobs and run your programs or SQL statements to process and analyze data.
4. MRS provides you with MRS Manager, an enterprise-class unified management platform of big data clusters, helping you quickly know the health status of services and hosts. Through graphical metric monitoring and customization, you can obtain critical system information in a timely manner. In addition, you can modify service attribute configurations based on service performance requirements, and start or stop clusters, services, and role instances in one click.
5. Terminate the cluster if it is no longer needed after job execution.

3.2 Creating a Cluster

The first step of using MRS is to create a cluster. This section describes how to create a cluster on the MRS console.

Procedure

Step 1 Log in to the MRS console.

Step 2 Click **Create Cluster** to access the **Create Cluster** page.

NOTE

When creating a cluster, pay attention to quota notification. If a resource quota is insufficient, increase the resource quota as prompted and create a cluster.

Step 3 On the page for create a cluster, click the **Custom Config** tab.

Step 4 Configure cluster software information.

- **Region**: Use the default value.
- **Cluster Name**: You can use the default name. However, you are advised to include a project name abbreviation or date for consolidated memory and easy distinguishing, for example, **mrs_20180321**.
- **Cluster Version**: Select the latest version, which is the default value.
- **Cluster Type**: Use the default **Custom**.
- **Version Type**: **Normal** (default) or **LTS**
- **Component**: Select components based on service requirement. Mandatory components are selected by default. Dependent components are automatically selected.
- **Component Port**: Retain the default value.

Step 5 Click **Next**.

- **AZ**: Use the default value.
- **Enterprise Project**: Select **default**.
- **VPC**: Use the default value. If there is no available VPC, click **View VPC** to access the VPC console and create a new VPC.
- **Subnet**: Use the default value.
- **Security Group**: Select **Auto create**.
- **EIP**: Select **Bind later**.
- **Enterprise Project**: Retain the default value.
- **Instance Specifications**: Retain the default settings for master and core nodes or select proper specifications based on service requirements.
- **System Disk**: Select **General Purpose SSD** and retain the default space.
- **Data Disk**: Select **General Purpose SSD** and retain the default space.
- **Instance Count**: The default number of Master nodes is 3, and that of Core nodes is 3. You can increase or decrease the number of instances based on service requirements.

Step 6 Click **Next**. The **Set Advanced Options** page is displayed. Configure the following parameters. Retain the default settings for the other parameters.

- Kerberos authentication:
  - **Kerberos Authentication**: Disable Kerberos authentication.
  - **Username**: name of the Manager administrator. **admin** is used by default.

  - **Password**: password of the Manager administrator.
- **Login Mode**: Select a mode for logging in to an ECS.
  - **Password**: Set a password for logging in to an ECS.
  - **Key Pair**: Select a key pair from the drop-down list. Select **"I acknowledge that I have obtained private key file *SSHkey-xxx* and that without this file I will not be able to log in to my ECS.**" If you have never created a key pair, click **View Key Pair** to create or import a key pair. And then, obtain a private key file.
- **Hostname Prefix**: Prefix for the name of an ECS or BMS in the cluster.

  Enter a maximum of 20 characters that do not start or end with a hyphen (-). Only letters, numbers, and hyphens (-) are allowed.

  When a cluster is created, a DNS domain name is registered for nodes in the cluster. The complete domain name is in the following format: **[prefix]-hostname.mrs-{*XXXX*}.com**. (*XXXX* is a four-character string generated based on the UUID.)
- **Set Advanced Options**: To configure some advanced parameters, select **Configure**.

Step 7 Click **Next**.

- **Configure**: Confirm the parameters configured in the **Configure Software**, **Configure Hardware**, and **Set Advanced Options** areas.
- **Secure Communications**: Select **Enable**.

Step 8 Click **Apply Now**.

If Kerberos authentication is enabled for a cluster, check whether Kerberos authentication is required. If yes, click **Continue**. If no, click **Back** to disable Kerberos authentication and then create a cluster.

Step 9 Click **Back to Cluster List** to view the cluster status.

It takes some time to create a cluster. The initial status of the cluster is **Starting**. After the cluster has been created successfully, the cluster status becomes **Running**.

----End

3.3 Uploading Data

On the **Files** page, you can create and delete HDFS directories, as well as import, export, and delete files in an analysis cluster.

For clusters with Kerberos authentication enabled, synchronize IAM users before performing operations on the **Files** page. On the cluster details page, click **Dashboard** and click **Synchronize** on the right of **IAM User Sync** to synchronize IAM users.

Background

MRS clusters generally process data from OBS or HDFS. OBS provides you with the data storage capabilities that are massive, secure, reliable, and cost-effective. MRS can directly process data in OBS. You can browse, manage, and use data both on

the management console and on the OBS Client. If you need to import OBS data into the HDFS system of the cluster for processing, perform the steps in this section.

Importing Data

Currently, MRS can import data from OBS to the HDFS. The file upload rate decreases with the increase of the file size. This mode applies to scenarios where the data volume is small.

You can perform the following steps to import files and directories:

1. Log in to the MRS console.
2. Choose **Clusters** > **Active Clusters**, and click the name of the target cluster to enter the cluster details page.
3. Click **Files** to go to the file management page.
4. Select **HDFS File List**.
5. Go to the data storage directory, for example, **bd_app1**.

   The **bd_app1** directory is only an example. You can use any directory on the page or create a new one.

   The requirements for creating a folder are as follows:

   - The folder name contains a maximum of 255 characters.
   - The folder name cannot be empty.
   - The folder name cannot contain the following special characters: /:*?"<>|\;&,'`!{}[]$%+
   - The value cannot start or end with a period (.).
   - The spaces at the beginning and end are ignored.
6. Click **Import Data** and configure the HDFS and OBS paths correctly. When configuring the OBS or HDFS path, click **Browse**, select a file directory, and click **Yes**.
   - OBS path
     - The path must start with **obs://**.
     - Files or programs encrypted by KMS cannot be imported.
     - An empty folder cannot be imported.
     - The directory and file name can contain letters, digits, hyphens (-), and underscores (_), but cannot contain special characters ;|&>,<'$*?\
     - The directory and file name cannot start or end with a space, but can contain spaces between them.
     - The OBS full path contains a maximum of 255 characters.
   - HDFS path
     - The path starts with **/user** by default.

- The directory and file name can contain letters, digits, hyphens (-), and underscores (_), but cannot contain the following special characters: ;|&>,<'$*?\:
- The directory and file name cannot start or end with a space, but can contain spaces between them.
- The HDFS full path contains a maximum of 255 characters.

7. Click **OK**.

   You can view the file upload progress on the **File Operation Records** page. MRS processes the data import operation as a DistCp job. You can also check whether the DistCp job is successfully executed on the **Jobs** page.

Exporting Data

After data analysis and computing is complete, you can store the data in the HDFS or export it to OBS.

You can perform the following steps to export files and directories:

1. Log in to the MRS console.
2. Choose **Clusters** > **Active Clusters**, and click the name of the target cluster to enter the cluster details page.
3. Click **Files** to go to the file management page.
4. Select **HDFS File List**.
5. Go to the data storage directory, for example, **bd_app1**.
6. Click **Export Data** and configure the OBS and HDFS paths. When configuring the OBS or HDFS path, click **Browse**, select a file directory, and click **Yes**.
   - OBS path
     - The path must start with **obs://**.
     - The directory and file name can contain letters, digits, hyphens (-), and underscores (_), but cannot contain special characters ;|&>,<'$*?\
     - The directory and file name cannot start or end with a space, but can contain spaces between them.
     - The OBS full path contains a maximum of 255 characters.
   - HDFS path
     - The path starts with **/user** by default.
     - The directory and file name can contain letters, digits, hyphens (-), and underscores (_), but cannot contain the following special characters: ;|&>,<'$*?\:
     - The directory and file name cannot start or end with a space, but can contain spaces between them.
     - The HDFS full path contains a maximum of 255 characters.

NOTE

When a folder is exported to OBS, a label file named **folder name_$folder$** is added to the OBS path. Ensure that the exported folder is not empty. If the exported folder is empty, OBS cannot display the folder and only generates a file named **folder name_$folder$**.

7. Click **OK**.

   You can view the file upload progress on the **File Operation Records** page. MRS processes the data export operation as a DistCp job. You can also check whether the DistCp job is successfully executed on the **Jobs** page.

3.4 Creating a Job

You can submit programs developed by yourself to MRS to execute them, and obtain the results.

This section describes how to submit a job (take a MapReduce job as an example) on the MRS console. MapReduce jobs are used to submit JAR programs to quickly process massive amounts of data in parallel and create a distributed data processing and execution environment.

If the job and file management functions are not supported on the cluster details page, submit the jobs in the background.

Before creating a job, you need to upload local data to OBS for data computing and analyzing. MRS allows exporting data from OBS to HDFS for computing and analyzing. After the data analysis and computing are completed, you can store the data in HDFS or export them to OBS. HDFS and OBS can also store the compressed data in the format of **bz2** or **gz**.

NOTE

If the IAM username contains spaces (for example, **admin 01**), a job cannot be created.

Submitting a Job on the GUI

Step 1 Log in to the MRS console.

Step 2 Choose **Clusters** > **Active Clusters**, select a running cluster, and click its name to access the cluster details page.

Step 3 If Kerberos authentication is enabled for the cluster, perform the following steps. If Kerberos authentication is not enabled for the cluster, skip this step.

In the **Basic Information** area on the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.

Step 4 Click the **Jobs** tab.

Step 5 Click **Create**. The **Create Job** dialog box is displayed.

Step 6 In **Type**, select **MapReduce**. Configure other job information.

Table 3-1 Job parameters

Parameter	Description
Name	Job name. It contains 1 to 64 characters. Only letters, digits, hyphens (-), and underscores (_) are allowed. **NOTE** You are advised to set different names for different jobs.
Program Path	Path of the program package to be executed. The following requirements must be met: • Contains a maximum of 1,023 characters, excluding special characters such as **;|&><'$**. The parameter value cannot be empty or full of spaces. • The path of the program to be executed can be stored in HDFS or OBS. The path varies depending on the file system. – OBS: The path starts with **obs://**. Example: **obs://wordcount/program/*xxx*.jar** – HDFS: The path must start with **/user**. • For SparkScript and HiveScript, the path must end with **.sql**. For MapReduce, the path must end with **.jar**. For Flink and SparkSubmit, the path must end with **.jar** or **.py**. The **.sql**, **.jar**, and **.py** are case-insensitive.
Parameters	(Optional) It is the key parameter for program execution. Separate multiple parameters with space. Configuration method: *Program class name Data input path Data output path* • Program class name: It is specified by a function in your program. MRS is responsible for transferring parameters only. • Data input path: Click **HDFS** or **OBS** to select a path or manually enter a correct path. • Data output path: Enter a directory that does not exist. The parameter contains a maximum of 150,000 characters. It cannot contain special characters ;|&><'$, but can be left blank. **CAUTION** If you enter a parameter with sensitive information (such as the login password), the parameter may be exposed in the job details display and log printing. Exercise caution when performing this operation.
Service Parameters	(Optional) Used to modify service configuration parameters for the job to be executed. The parameter modification applies only to the job to be executed. To add multiple parameters, click ⊕ on the right. To delete a parameter, click **Delete** on the right. **Table 3-2** describes the common parameters of a service.

Parameter	Description
Command Reference	Command submitted to the background for execution when a job is submitted.

Table 3-2 Service configuration parameters

Parameter	Description	Example Value
fs.obs.access.key	Key ID for accessing OBS.	-
fs.obs.secret.key	Key corresponding to the key ID for accessing OBS.	-

Step 7 Confirm job configuration information and click **OK**.

After the job is created, you can manage it.

----End

3.5 Terminating a Cluster

You can terminate an MRS cluster that is no longer use after job execution is complete.

Background

Typically after data is analyzed and stored, or when the cluster encounters an exception and cannot work, you can terminate a cluster. A cluster failed to be deployed will be automatically terminated.

Procedure

Step 1 Log in to the MRS management console.

Step 2 In the navigation pane on the left, choose **Clusters** > **Active Clusters**.

Step 3 In the cluster list, locate the row containing the cluster to be terminated, and click **Terminate** in the **Operation** column.

The cluster status changes from **Running** to **Terminating**, and finally to **Terminated**. You can view the terminated cluster in **Cluster History**.

----End

3.6 Using Clusters with Kerberos Authentication Enabled

This section instructs you to use security clusters and run MapReduce, Spark, and Hive programs.

You can get started by reading the following topics:

1. **Creating a Security Cluster and Logging In to Manager**
2. **Creating a Role and a User**
3. **Running a MapReduce Program**
4. **Running a Spark Program**
5. **Running a Hive Program**

Creating a Security Cluster and Logging In to Manager

Step 1 Create a security cluster. Enable **Kerberos Authentication**, configure **Password**, and confirm the password. This password is used to log in to Manager. Keep it secure.

Step 2 Log in to the MRS console.

Step 3 In the navigation pane on the left, choose **Active Clusters** and click the target cluster name on the right to access the cluster details page.

Step 4 Click **Access Manager** on the right of **MRS Manager** to log in to Manager.

- If you have bound an EIP when creating the cluster, perform the following operations:
  a. Add a security group rule. By default, your public IP address used for accessing port 9022 is filled in the rule. If you want to view, modify, or delete a security group rule, click **Manage Security Group Rule**.

     NOTE

     - It is normal that the automatically generated public IP address is different from your local IP address and no action is required.
     - If port 9022 is a Knox port, you need to enable the permission to access port 9022 of Knox for accessing Manager.

  b. Select **I confirm that xx.xx.xx.xx is a trusted public IP address and MRS Manager can be accessed using this IP address.**
- If you have not bound an EIP when creating the cluster, perform the following operations:
  a. Select an EIP from the drop-down list or click **Manage EIP** to create one.
  b. Add a security group rule. By default, your public IP address used for accessing port 9022 is filled in the rule. If you want to view, modify, or delete a security group rule, click **Manage Security Group Rule**.

NOTE

- It is normal that the automatically generated public IP address is different from the local IP address and no action is required.
- If port 9022 is a Knox port, you need to enable the permission of port 9022 to access Knox for accessing MRS Manager.

c. Select **I confirm that xx.xx.xx.xx is a trusted public IP address and MRS Manager can be accessed using this IP address.**

Step 5 Click **OK**. The Manager login page is displayed. To assign other users the permission to access Manager, add the IP addresses as trusted ones.

NOTE

Before accessing Manager, ensure that the EIP can be pinged. If the ping operation fails, contact technical support.

Step 6 Enter the default username **admin** and the password you set when creating the cluster, and click **Log In**.

----End

Creating a Role and a User

For clusters with Kerberos authentication enabled, perform the following steps to create a user and assign permissions to the user to run programs.

Step 1 On Manager, choose **System** > **Permission** > **Role**.

Step 2 Click **Create Role**.

Specify the following information:

- Enter a role name, for example, **mrrole**.
- In **Configure Resource Permission**, select the cluster to be operated, choose **Yarn** > **Scheduler Queue** > **root**, and select **Submit** and **Admin** in the **Permission** column. After you finish configuration, do not click **OK** but click the name of the target cluster shown in the following figure and then configure other permissions.
- Choose **HBase** > **HBase Scope**. Locate the row that contains **global**, and select **create**, **read**, **write**, and **execute** in the **Permission** column. After you finish configuration, do not click **OK** but click the name of the target cluster shown in the following figure and then configure other permissions.
- Choose **HDFS** > **File System** > **hdfs://hacluster/** and select **Read**, **Write**, and **Execute** in the **Permission** column. After you finish configuration, do not click **OK** but click the name of the target cluster shown in the following figure and then configure other permissions.
- Choose **Hive** > **Hive Read Write Privileges**, select **Select**, **Delete**, **Insert**, and **Create** in the **Permission** column, and click **OK**.

Step 3 Choose **System**. In the navigation pane on the left, choose **Permission** > **User Group** > **Create User Group** to create a user group for the sample project, for example, **mrgroup**.

Step 4 Choose **System**. In the navigation pane on the left, choose **Permission** > **User** > **Create** to create a user for the sample project.

- Enter a username, for example, **test**. If you want to run a Hive program, enter **hiveuser** in **Username**.
- Set **User Type** to **Human-Machine**.
- Enter a password. This password will be used when you run the program.
- In **User Group**, add **mrgroup** and **supergroup**.
- Set **Primary Group** to **supergroup** and bind the **mrrole** role to obtain the permission.

  Click **OK**.

Step 5 Choose **System**. In the navigation pane on the left, choose **Permission** > **User**, locate the row where user **test** locates, and select **Download Authentication Credential** from the **More** drop-down list. Save the downloaded package and decompress it to obtain the **keytab** and **krb5.conf** files.

----End

Running a MapReduce Program

This section describes how to run a MapReduce program in security cluster mode.

Prerequisites

You have compiled the program and prepared data files, for example, **mapreduce-examples-1.0.jar**, **input_data1.txt**, and **input_data2.txt**..

Procedure

Step 1 Use a remote login software (for example, MobaXterm) to log in to the master node of the security cluster using SSH (using the EIP).

Step 2 After the login is successful, run the following commands to create the **test** folder in the **/opt/Bigdata/client** directory and create the **conf** folder in the **test** directory:

```
cd /opt/Bigdata/client
mkdir test
cd test
mkdir conf
```

Step 3 Use an upload tool (for example, WinSCP) to copy **mapreduce-examples-1.0.jar**, **input_data1.txt**, and **input_data2.txt** to the **test** directory, and copy the **keytab** and **krb5.conf** files obtained in **Step 5** in **Creating Roles and Users** to the **conf** directory.

Step 4 Run the following commands to configure environment variables and authenticate the created user, for example, **test**:

```
cd /opt/Bigdata/client
source bigdata_env
export YARN_USER_CLASSPATH=/opt/Bigdata/client/test/conf/
kinit test
```

Enter the password as prompted. If no error message is displayed (you need to change the password as prompted upon the first login), Kerberos authentication is complete.

Step 5 Run the following commands to import data to the HDFS:

```
cd test
hdfs dfs -mkdir /tmp/input
hdfs dfs -put input_data* /tmp/input
```

Step 6 Run the following commands to run the program:

```
yarn jar mapreduce-examples-1.0.jar com.huawei.bigdata.mapreduce.examples.FemaleInfoCollector /tmp/input /tmp/mapreduce_output
```

In the preceding commands:

/tmp/input indicates the input path in the HDFS.

/tmp/mapreduce_output indicates the output path in the HDFS. This directory must not exist. Otherwise, an error will be reported.

Step 7 After the program is executed successfully, run the **hdfs dfs -ls /tmp/mapreduce_output** command. The following command output is displayed.

Figure 3-1 Program running result

```
[root@node-master1-SsjQd test]# hdfs dfs -ls /tmp/mapreduce_output
Found 2 items
-rw-r--r--+  2 test hadoop          0 2018-08-20 20:53 /tmp/mapreduce_output/_
SUCCESS
-rw-r--r--+  2 test hadoop         23 2018-08-20 20:53 /tmp/mapreduce_output/p
art-r-00000
[root@node-master1-SsjQd test]#
```

----End

Running a Spark Program

This section describes how to run a Spark program in security cluster mode.

Prerequisites

You have compiled the program and prepared data files, for example, **FemaleInfoCollection.jar**, **input_data1.txt**, and **input_data2.txt**..

Procedure

Step 1 Use a remote login software (for example, MobaXterm) to log in to the master node of the security cluster using SSH (using the EIP).

Step 2 After the login is successful, run the following commands to create the **test** folder in the **/opt/Bigdata/client** directory and create the **conf** folder in the **test** directory:

```
cd /opt/Bigdata/client
mkdir test
cd test
mkdir conf
```

Step 3 Use an upload tool (for example, WinSCP) to copy **FemaleInfoCollection.jar**, **input_data1.txt**, and **input_data2.txt** to the **test** directory, and copy the **keytab** and **krb5.conf** files obtained in **Step 5** in section **Creating Roles and Users** to the **conf** directory.

Step 4 Run the following commands to configure environment variables and authenticate the created user, for example, **test**:

```
cd /opt/Bigdata/client
source bigdata_env
```

```
export YARN_USER_CLASSPATH=/opt/Bigdata/client/test/conf/
kinit test
```

Enter the password as prompted. If no error message is displayed, Kerberos authentication is complete.

Step 5 Run the following commands to import data to the HDFS:

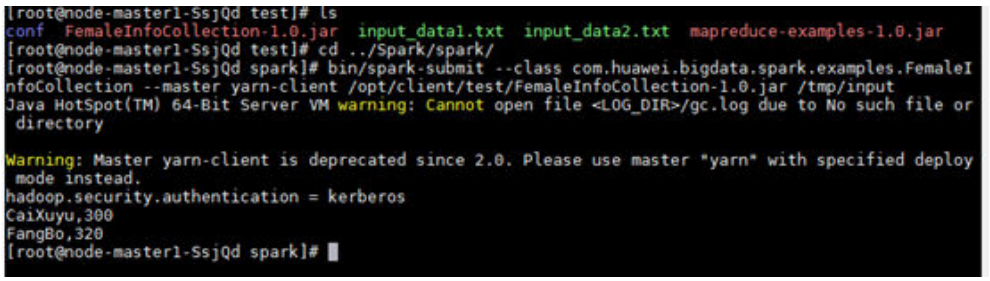
```
cd test
hdfs dfs -mkdir /tmp/input
hdfs dfs -put input_data* /tmp/input
```

Step 6 Run the following commands to run the program:

```
cd /opt/Bigdata/client/Spark/spark
bin/spark-submit --class com.huawei.bigdata.spark.examples.FemaleInfoCollection --master yarn-client /opt/Bigdata/client/test/FemaleInfoCollection-1.0.jar /tmp/input
```

Step 7 After the program is run successfully, the following information is displayed.

Figure 3-2 Program running result



----End

Running a Hive Program

This section describes how to run a Hive program in security cluster mode.

Prerequisites

You have compiled the program and prepared data files, for example, **hive-examples-1.0.jar**, **input_data1.txt**, and **input_data2.txt**..

Procedure

Step 1 Use a remote login software (for example, MobaXterm) to log in to the master node of the security cluster using SSH (using the EIP).

Step 2 After the login is successful, run the following commands to create the **test** folder in the **/opt/Bigdata/client** directory and create the **conf** folder in the **test** directory:

```
cd /opt/Bigdata/client
mkdir test
cd test
mkdir conf
```

Step 3 Use an upload tool (for example, WinSCP) to copy **FemaleInfoCollection.jar**, **input_data1.txt**, and **input_data2.txt** to the **test** directory, and copy the **keytab** and **krb5.conf** files obtained in **Step 5** in section **Creating Roles and Users** to the **conf** directory.

Step 4 Run the following commands to configure environment variables and authenticate the created user, for example, **test**:

```
cd /opt/Bigdata/client
source bigdata_env
export YARN_USER_CLASSPATH=/opt/Bigdata/client/test/conf/
kinit test
```

Enter the password as prompted. If no error message is displayed, Kerberos authentication is complete.

Step 5 Run the following command to run the program:

```
chmod +x /opt/hive_examples -R   cd /opt/hive_examples   java -cp .:hive-examples-1.0.jar:/opt/
hive_examples/conf:/opt/Bigdata/client/Hive/Beeline/lib/*:/opt/Bigdata/client/HDFS/hadoop/lib/*
com.huawei.bigdata.hive.example.ExampleMain
```

Step 6 After the program is run successfully, the following information is displayed.

Figure 3-3 Program running result

```
[root@node-master1-iYpxp hive_examples]# java -cp .:hive-examples-mrs-1.7.0.jar:
/opt/hive_examples/conf:/opt/client/Hive/Beeline/lib/*:/opt/client/HDFS/hadoop/l

4 Configuring a Cluster

4.1 How to Create an MRS Cluster

This section describes how to create an MRS cluster.

- **Quickly Creating a Hadoop Analysis Cluster**: In the **Quick Config** tab, you can quickly configure parameters to create a Hadoop analysis cluster within a few minutes, facilitating analysis and queries of vast amounts of data.
- **Quickly Creating an HBase Query Cluster**: In the **Quick Config** tab, you can quickly configure parameters to create an HBase query cluster within a few minutes, facilitating storage and distributed computing of vast amounts of data.
- **Quickly Creating a ClickHouse Cluster**: You can quickly create a ClickHouse cluster. ClickHouse is a columnar database management system used for online analysis. It features optimal compression rate and fast query performance.
- **Quickly Creating a Real-time Analysis Cluster**: You can create a real-time analysis cluster within a few minutes to quickly collect, analyze, and query a large amount of data.
- **Creating a Custom Cluster**: On the **Custom Config** tab page, you can flexibly configure parameters to create clusters based on application scenarios, such as ECS specifications to better suit your service requirements.

4.2 Quick Configuration

4.2.1 Quickly Creating a Hadoop Analysis Cluster

This section describes how to quickly create a Hadoop analysis cluster for analysis and query of vast amounts of data. In the open source Hadoop ecosystem, Hadoop uses YARN to manage cluster resources, Hive and Spark to provide offline storage and computing of large-scale distributed data, Spark Streaming and Flink to offer streaming data computing, and Presto to enable interactive queries, Tez to provide a distributed computing framework of directed acyclic graphs (DAGs).

Quickly Creating a Hadoop Analysis Cluster

Step 1 On the displayed page, click the **Quick Config** tab.

Step 2 Configure basic cluster information. For details about the parameters, see **Creating a Custom Cluster**.

- **Region**: Use the default value.
- **Cluster Name**: You can use the default name. However, you are advised to include a project name abbreviation or date for consolidated memory and easy distinguishing, for example, **mrs_20180321**.
- **Cluster Type**: Use the default value.
- **Version Type**: **Normal** is selected by default. (Components vary depending on the version type. Select a version type as needed.)
- **Cluster Version**: Select the latest version, which is the default value. (The components provided by a cluster vary according to the cluster version. Select a cluster version based on site requirements.)
- **Component**: Select **Hadoop analysis cluster**.
- **AZ**: Use the default value.
- **Enterprise Project**: Retain the default value.
- **VPC**: Use the default value. If there is no available VPC, click **View VPC** to access the VPC console and create a new VPC.
- **Subnet**: Use the default value.
- **CPU Architecture**: Use the default value.
- **Cluster Node**: Select the number of cluster nodes and node specifications based on site requirements.
- **Username**: The default value is **root/admin**. User **root** is used to remotely log in to ECSs, and user **admin** is used to access the cluster management page.
- **Password**: Set a password for user **root**/**admin**.
- **Confirm Password**: Enter the password of user **root**/**admin** again.

Step 3 Select the checkbox to enable secure communications. For details, see **Communication Security Authorization**.

Step 4 Click **Create Now**.

If Kerberos authentication is enabled, check whether this function is required. If it is, click **Continue**. If not, click **Back** to disable it and then proceed with the subsequent step. This option cannot be changed after you create a cluster.

Step 5 Click **Back to Cluster List** to view the cluster status. Click **Access Cluster** to view cluster details.

For details about cluster status during creation, see the description of the status parameters in **Table 5-4**.

It takes some time to create a cluster. The initial status of the cluster is **Starting**. After the cluster has been created successfully, the cluster status becomes **Running**.

On the MRS management console, a maximum of 10 clusters can be concurrently created, and a maximum of 100 clusters can be managed.

----End

4.2.2 Quickly Creating an HBase Query Cluster

This section describes how to quickly create an HBase query cluster. The HBase cluster uses Hadoop and HBase components to provide a column-oriented distributed cloud storage system featuring enhanced reliability, excellent performance, and elastic scalability. It applies to the storage and distributed computing of massive amounts of data. You can use HBase to build a storage system capable of storing TB- or even PB-level data. With HBase, you can filter and analyze data with ease and get responses in milliseconds, rapidly mining data value.

Quickly Creating an HBase Query Cluster

Step 1 On the displayed page, click the **Quick Config** tab.

Step 2 Configure basic cluster information. For details about the parameters, see **Creating a Custom Cluster**.

- **Region**: Use the default value.
- **Cluster Name**: You can use the default name. However, you are advised to include a project name abbreviation or date for consolidated memory and easy distinguishing, for example, **mrs_20180321**.
- **Cluster Type**: Use the default value.
- **Version Type**: **Normal** is selected by default. (Components vary depending on the version type. Select a version type as needed.)
- **Cluster Version**: Select the latest version, which is the default value. (The components provided by a cluster vary according to the cluster version. Select a cluster version based on site requirements.)
- **Component**: Select **HBase Query Cluster**.
- **AZ**: Use the default value.
- **Enterprise Project**: Retain the default value.
- **VPC**: Use the default value. If there is no available VPC, click **View VPC** to access the VPC console and create a new VPC.
- **Subnet**: Use the default value.
- **Enterprise Project**: Select the default project.
- **Cluster Node**: Select the number of cluster nodes and node specifications based on site requirements.
- **Username**: The default value is **root**/**admin**. User **root** is used to remotely log in to ECSs and user **admin** is used to access FusionInsight Manager.
- **Password**: Set a password for user **root**/**admin**.
- **Confirm Password**: Enter the password of user **root**/**admin** again.

Step 3 Select the checkbox to enable secure communications. For details, see **Communication Security Authorization**.

Step 4 Click **Create Now**.

If Kerberos authentication is enabled, check whether this function is required. If it is, click **Continue**. If not, click **Back** to disable it and then proceed with the subsequent step. This option cannot be changed after you create a cluster.

Step 5 Click **Back to Cluster List** to view the cluster status. Click **Access Cluster** to view cluster details.

For details about cluster status during creation, see the description of the status parameters in **Table 5-4**.

It takes some time to create a cluster. The initial status of the cluster is **Starting**. After the cluster has been created successfully, the cluster status becomes **Running**.

On the MRS management console, a maximum of 10 clusters can be concurrently created, and a maximum of 100 clusters can be managed.

----End

4.2.3 Quickly Creating a ClickHouse Cluster

This section describes how to quickly create a ClickHouse cluster. ClickHouse is a columnar database management system used for online analysis. It features optimal compression rate and fast query performance. It is widely used in Internet advertisement, app and web traffic analysis, telecom, finance, and IoT fields.

The ClickHouse cluster table engine that uses Kunpeng as the CPU architecture does not support HDFS and Kafka.

Quickly Creating a ClickHouse Cluster

Step 1 On the displayed page, click the **Quick Config** tab.

Step 2 Configure basic cluster information. For details about the parameters, see **Creating a Custom Cluster**.

- **Region**: Use the default value.
- **Cluster Name**: You can use the default name. However, you are advised to include a project name abbreviation or date for consolidated memory and easy distinguishing, Example: **mrs_20201121**.
- **Cluster Type**: Use the default value.
- **Version Type**: **Normal** is selected by default. (Components vary depending on the version type. Select a version type as needed.)
- **Cluster Version**: Select the latest version, which is the default value. (The components provided by a cluster vary according to the cluster version. Select a cluster version based on site requirements.)
- **Component**: Select **ClickHouse cluster**.
- **AZ**: Use the default value.
- **Enterprise Project**: Retain the default value.
- **VPC**: Use the default value. If there is no available VPC, click **View VPC** to access the VPC console and create a new VPC.

- **Subnet**: Use the default value.
- **CPU Architecture**: Retain the default value.
- **Cluster Node**: Select the number of cluster nodes and node specifications based on site requirements.
- **Username**: The default value is **root**/**admin**. User **root** is used to remotely log in to ECSs and user **admin** is used to access FusionInsight Manager.
- **Password**: Set a password for user **root**/**admin**.
- **Confirm Password**: Enter the password of user **root**/**admin** again.

Step 3 Select the checkbox to enable secure communications. For details, see **Communication Security Authorization**.

Step 4 Click **Create Now**.

If Kerberos authentication is enabled, check whether this function is required. If it is, click **Continue**. If not, click **Back** to disable it and then proceed with the subsequent step. This option cannot be changed after you create a cluster.

Step 5 Click **Back to Cluster List** to view the cluster status. Click **Access Cluster** to view cluster details.

For details about cluster status during creation, see the description of the status parameters in **Table 5-4**.

It takes some time to create a cluster. The initial status of the cluster is **Starting**. After the cluster has been created successfully, the cluster status becomes **Running**.

On the MRS management console, a maximum of 10 clusters can be concurrently created, and a maximum of 100 clusters can be managed.

----End

4.2.4 Quickly Creating a Real-time Analysis Cluster

This section describes how to quickly create a real-time analysis cluster. The real-time analysis cluster uses Hadoop, Kafka, Flink, and ClickHouse to collect, analyze, and query a large amount of data in real time.

Quickly Creating a Real-time Analysis Cluster

Step 1 On the displayed page, click the **Quick Config** tab.

Step 2 Configure basic cluster information. For details about the parameters, see **Creating a Custom Cluster**.

- **Region**: Use the default value.
- **Cluster Name**: You can use the default name. However, you are advised to include a project name abbreviation or date for consolidated memory and easy distinguishing, Example: **mrs_20201130**.
- **Cluster Type**: Use the default value.
- **Version Type**: **Normal** is selected by default. (Components vary depending on the version type. Select a version type as needed.)

- **Cluster Version**: Select the latest version, which is the default value. (The components provided by a cluster vary according to the cluster version. Select a cluster version based on site requirements.)
- **Component**: Select **Real-time Analysis Cluster**.
- **AZ**: Use the default value.
- **VPC**: Use the default value. If there is no available VPC, click **View VPC** to access the VPC console and create a new VPC.
- **Subnet**: Use the default value.
- **Enterprise Project**: Use the default value.
- **CPU Architecture**: Retain the default value.
- **Cluster Node**: Select the number of cluster nodes and node specifications based on site requirements.
- **Username**: The default value is **root**/**admin**. User **root** is used to remotely log in to ECSs and user **admin** is used to access FusionInsight Manager.
- **Password**: Set a password for user **root**/**admin**.
- **Confirm Password**: Enter the password of user **root**/**admin** again.

Step 3 Select the checkbox to enable secure communications. For details, see **Communication Security Authorization**.

Step 4 Click **Create Now**.

If Kerberos authentication is enabled, check whether this function is required. If it is, click **Continue**. If not, click **Back** to disable it and then proceed with the subsequent step. This option cannot be changed after you create a cluster.

Step 5 Click **Back to Cluster List** to view the cluster status. Click **Access Cluster** to view cluster details.

For details about cluster status during creation, see the description of the status parameters in **Table 5-4**.

It takes some time to create a cluster. The initial status of the cluster is **Starting**. After the cluster has been created successfully, the cluster status becomes **Running**.

On the MRS management console, a maximum of 10 clusters can be concurrently created, and a maximum of 100 clusters can be managed.

----End

4.3 Creating a Custom Cluster

To use MRS, create a cluster on the MRS management console.

You can create an IAM user or user group on the IAM management console and grant it specific operation permissions, to perform refined resource management after registering an account. For details, see **Creating an MRS User**.

Step 1 Click the **Custom Config** tab.

NOTE

When creating a cluster, pay attention to quota notification. If a resource quota is insufficient, increase the resource quota as prompted and create a cluster.

Step 2 Configure cluster information by referring to **Software Configurations** and click **Next**.

NOTE

Only one billing mode is supported in some regions. For details, see the management console.

Step 3 Configure cluster information by referring to **Hardware Configurations** and click **Next**.

Step 4 Set advanced options by referring to **Advanced Options**. Then, click **Next**.

If Kerberos authentication is enabled, check whether this function is required. If it is, click **Continue**. If not, click **Back** to disable it and then proceed with the subsequent steps. This option cannot be changed after you create a cluster.

Step 5 On the **Confirm Configuration** page, check the cluster configuration information.

If you need to adjust the configuration, click  to go to the corresponding tab page and configure parameters again.

Step 6 Select the checkbox to enable secure communications. For details, see **Communication Security Authorization**.

Step 7 Click **Back to Cluster List** to view the cluster status.

For details about cluster status during creation, see the description of the status parameters in **Table 5-4**.

It takes some time to create a cluster. The initial status of the cluster is **Starting**. After the cluster has been created successfully, the cluster status becomes **Running**.

On the MRS management console, a maximum of 10 clusters can be concurrently created, and a maximum of 100 clusters can be managed.

----End

Software Configurations

Table 4-1 MRS cluster software configuration

Parameter	Description
Region	Select a region. Cloud service products in different regions cannot communicate with each other over an intranet. For low network latency and quick access, select the nearest region.

Parameter	Description
Cluster Name	The cluster name must be unique. A cluster name can contain 1 to 64 characters. Only letters, digits, hyphens (-), and underscores (_) are allowed. The default name is **mrs**_*xxxx*. *xxxx* is a random collection of letters and digits.
Cluster Type	The cluster types are as follows: • **Analysis cluster**: is used for offline data analysis and provides Hadoop components. • **Streaming cluster**: is used for streaming tasks and provides stream processing components. • **Hybrid cluster**: is used for both offline data analysis and streaming processing and provides Hadoop components and streaming processing components. You are advised to use a hybrid cluster to perform offline data analysis and streaming processing tasks at the same time. • **Custom**: You can adjust the cluster service deployment mode based on service requirements. For details, see **Configuring Custom Topology**. **NOTE** • MRS streaming clusters do not support job and file management functions. • To install all components in a cluster, select **Custom**.
Version Type	The following version types are available: • Normal: – Supports basic cluster operations, such as configuration, management, and O&M. – Supports components such as Presto, Impala, Kudu, and Sqoop. • LTS: – In addition to basic cluster operations, the LTS version supports version upgrade. – Supports multi-AZ deployment. – Supports HetuEngine, IoTDB, and CDL. The default version type is **Normal**.
Cluster Version	Currently, MRS 3.3.1-LTS is supported.
Component	MRS cluster components. For details about component versions supported by different versions of MRS clusters, see .

Parameter	Description
Metadata	Whether to use external data sources to store metadata. • **Local**: Metadata is stored in the local cluster. • **External data connection**: Metadata of external data sources is used. If the cluster is abnormal or deleted, metadata is not affected. This mode applies to scenarios where storage and compute are decoupled. Clusters that support the Hive or Ranger component support this function.
Component	This parameter is available only when **Metadata** is set to **External data connection**. It indicates the type of an external data source. • Hive • Ranger
Data Connection Type	This parameter is available only when **Metadata** is set to **External data connection**. It indicates the type of an external data source. When you create a cluster, **Data Connection Type** can only be set to **Local database**.
Component port (supported only for the LTS version)	Policy of the default communication port of each component in the MRS cluster. • Open source: Use the port provided by the open source component. • Custom: Customize a port for the component. For details about the differences between default open source port and default custom port, see **Web UIs of Open Source Components**.

Hardware Configurations

Table 4-2 MRS cluster hardware configuration

Parameter	Description
AZ	Select the AZ associated with the region of the cluster. An AZ is a physical area that uses independent power and network resources. AZs are physically isolated but interconnected through the internal network. This improves the availability of applications. You are advised to create clusters in different AZs.

Parameter	Description
Enterprise Project	Select the enterprise project to which the cluster belongs. To use an enterprise project, create one on the **Enterprise** > **Project Management** page. The **Enterprise Management** console of the enterprise project is designed for resource management. It helps enterprises manage cloud-based personnel, resources, permissions, and finance in a hierarchical manner, such as management of companies, departments, and projects.
VPC	A VPC is a secure, isolated, and logical network environment. Select the VPC for which you want to create a cluster and click **View VPC** to view the name and ID of the VPC. If no VPC is available, create one.
Subnet	A subnet provides dedicated network resources that are isolated from other networks, improving network security. Select the subnet for which you want to create a cluster. Click **View Subnet** to view details about the selected subnet. If no subnet is created in the VPC, go to the VPC console and choose **Subnets** > **Create Subnet** to create one. For details about how to configure network ACL outbound rules, see **How Do I Configure a Network ACL Outbound Rule?** **NOTE** The number of IP addresses required by creating an MRS cluster depends on the number of cluster nodes and selected components, but not the cluster type. In MRS, IP addresses are automatically assigned to clusters during cluster creation basically based on the following formula: Quantity of IP addresses = Number of cluster nodes + 2 (one for Manager; one for the DB). In addition, if the Hadoop, Hue, Sqoop, and Presto or Solr, GraphBase, Loader and Presto components are selected during cluster deployment, one IP address is added for each component. To create a ClickHouse cluster independently, the number of IP addresses required is calculated as follows: Number of IP addresses = Number of cluster nodes + 1 (for Manager).

Parameter	Description
Security Group	A security group is a set of ECS access rules. It provides access policies for ECSs that have the same security protection requirements and are mutually trusted in a VPC. When you create a cluster, you can select **Auto create** from the drop-down list of **Security Group** to create a security group or select an existing security group. **NOTE** When you select a security group created by yourself, ensure that the inbound rule contains a rule in which **Protocol** is set to **All**, **Port** is set to **All**, and **Source** is set to a trusted accessible IP address range. Do not use **0.0.0.0/0** as a source address. Otherwise, security risks may occur. If you do not know the trusted accessible IP address range, select **Auto create**.
EIP	After binding an EIP to an MRS cluster, you can use the EIP to access the Manager web UI of the cluster. When creating a cluster, you can select an available EIP from the drop-down list and bind it. If no EIP is available in the drop-down list, click **Manage EIP** to access the **EIPs** service page to create one. **NOTE** The EIP must be in the same region as the cluster.

Table 4-3 Cluster node information

Parameter	Description
CPU Architecture	CPU architecture supported by MRS. ● **x86**: The x86-based CPU architecture uses Complex Instruction Set Computing (CISC). Each instruction can be used to execute low-level hardware operations. The number of instructions is large, and the length of each instruction is different. Therefore, executing such an instruction is complex and time-consuming. ● **Kunpeng**: The Kunpeng-based CPU architecture uses Reduced Instruction Set Computing (RISC). RISC is a microprocessor that executes fewer types of computer instructions but at a higher speed than CISC. RISC simplifies the computer architecture and improves the running speed. Compared with the x86-based CPU architecture, the Kunpeng-based CPU architecture has a more balanced performance and power consumption ratio. Kunpeng features high density, low power consumption, high cost-effectiveness.

Parameter	Description
Common Node Configurations	This parameter is available only when **Cluster Type** is set to **Custom**. Value options include **Compact**, **Full-size**, and **OMS-separate**. For details, see **Custom Cluster Template Description**.
Node Group	Name of a node group An MRS cluster consists of multiple ECS nodes. The system manages the nodes based on node groups. Nodes in a cluster are classified into the following types based on the roles of components deployed on the nodes: • Master: manages the cluster and allocates cluster executable files to core nodes. traces the execution status of each job, and monitors the DataNode running status. • Core: cluster worker node, which processes and analyzes data and stores process data. The system automatically creates a core node group based on the components contained in the cluster. For example, if you select the ClickHouse component, the system adds the ClickHouse node group and deploys the ClickHouseServer role in the node group by default. • Task: provides compute resources, on which Yarn and Storm are installed. Task nodes do not store persistent data. When compute resources in a cluster are insufficient, you can configure auto scaling policies to automatically increase task nodes. When the data volume change is small in a cluster but the cluster's service processing capabilities need to be remarkably and temporarily improved, add Task nodes to address the following situations: For clusters whose **Cluster Type** is **Analysis cluster**, **Streaming cluster** , and **Hybrid cluster**, the system automatically adds the corresponding task node groups. You can delete the task node groups if they are not required.
Node Type	Type of the nodes in the group. Options include **Core** and **Task**. **NOTE** If the node group type is set to **Task**, only the **NodeManager** role (except mandatory roles) can be deployed in the node group.

Parameter	Description
Node Count	Configure node quantity in each node group. • Master Node Groups: The number of Master instances ranges from 3 to 9. • At least one Core node must exist and the total number of Core and Task nodes cannot exceed 10,000. Click ⊕ to add a node group, click ✎ to modify the node instance specifications, and click 🗑 to delete the added node group. **NOTE** A small number of nodes may cause clusters to run slowly while a large number of nodes may be unnecessarily costly. Set an appropriate value based on data to be processed.
Instance Specifications	Instance specifications of Master or Core nodes. MRS supports host specifications determined by CPU, memory, and disk space. Click ✎ to configure the instance specifications, system disk, and data disk parameters of the cluster node. **NOTE** • More advanced instance specifications provide better data processing. • Instance specifications may vary in different AZs. If no instance specifications in the current AZ can meet your requirements, switch to another AZ. • If you select non-HDD disks for Core nodes, the disk types of Master and Core nodes are determined by **Data Disk**. • If **Sold out** appears next to an instance specification of a node, the node of this specification cannot be created. You can only create nodes of other specifications. • The memory of the master node must be greater than 64 GB.
System Disk	Storage type and storage space of the system disk on a node. Storage type can be any of the following: • **SAS**: high I/O • **SSD**: ultra-high I/O • **GPSSD**: general-purpose SSD

Parameter	Description
Data Disk	Data disk storage space of a node. For more data storage, you can add disks when creating a cluster. A maximum of 10 disks can be added to each Core or Task node. ● Data storage and computing are separated. Data is stored in OBS, which features low cost and unlimited storage capacity. The clusters can be deleted at any time in OBS. The computing performance is determined by OBS access performance and is lower than that of HDFS. This configuration is recommended if data computing is infrequent. ● Data storage and computing are not separated. Data is stored in HDFS, which features high cost, high computing performance, and limited storage capacity. Before deleting clusters, you must export and store the data. This configuration is recommended if data computing is frequent. The storage type can be any of the following: ● SAS: high I/O ● SSD: ultra-high I/O ● GPSSD: general-purpose SSD **NOTE** More nodes in a cluster require higher disk capacity of Master nodes. To ensure stable cluster running, set the disk capacity of the Master node to over 600 GB if the number of nodes is 300 and increase it to over 1 TB if the number of nodes reaches 500.
Instance Count	Number of Master and Core nodes. ● Master Node Groups: The number of Master instances ranges from 3 to 9. ● At least one Core node must exist and the total number of Core and Task nodes cannot exceed 10,000. Click ⊕ to add a node group, click ✎ to modify the node instance specifications, and click 🗑 to delete the added node group. **NOTE** A small number of nodes may cause clusters to run slowly while a large number of nodes may be unnecessarily costly. Set an appropriate value based on data to be processed.

Parameter	Description
Topology Adjustment	If the deployment mode in the **Common Node** does not meet the requirements, set **Topology Adjustment** to **Enable** and adjust the instance deployment mode based on service requirements. For details, see **Topology Adjustment for a Custom Cluster**. This parameter is valid only when **Cluster Type** is set to **Custom**.

Advanced Options

Table 4-4 MRS cluster advanced configuration topology

Parameter	Description
Kerberos Authentication	Whether to enable Kerberos authentication when logging in to Manager. This option cannot be changed after you create a cluster. •  : If **Kerberos Authentication** is disabled, common users can use all functions of an MRS cluster. You are advised to disable Kerberos authentication in single-user scenarios. If Kerberos authentication is disabled, you can follow instructions in **Security Configuration Suggestions for Clusters with Kerberos Authentication Disabled** to perform security configuration. •  : If **Kerberos Authentication** is enabled, common users cannot use the file and job management functions of an MRS cluster and cannot view cluster resource usage or the job records for Hadoop and Spark. To use more cluster functions, the users must contact the Manager administrator to assign more permissions. You are advised to enable Kerberos authentication in multi-user scenarios. • Currently, Presto does not support Kerberos authentication.
Username	Name of the administrator of Manager. **admin** is used by default.

Parameter	Description
Password	Password of the Manager administrator The following requirements must be met: ● Must contain 8 to 26 characters. ● Must contain at least four of the following: – Lowercase letters – Uppercase letters – Digits – At least one of the following special characters: `~!@#$%^&*()-_=+|[{}];:',<.>/? ● Cannot be the same as the username or the username spelled backwards. Password Strength: The colorbar in red, orange, and green indicates weak, medium, and strong password, respectively.
Confirm Password	Enter the password of the Manager administrator again.

Parameter	Description
Login Mode	• Password Log in to the ECS as user **root**. Enter the password of user **root** and confirm the password. A password must meet the following requirements: 1. Must be a string and 8 to 26 characters long. 2. Must contain at least four of the following: uppercase letters, lowercase letters, digits, and special characters (`~!@#$%^&*()-_=+|[{}];:',<.>/?). 3. The password cannot be the username or the reverse username. • Key Pair Key pairs are used to log in to ECS nodes of the cluster. Select a key pair from the drop-down list. Select "I acknowledge that I have obtained private key file *SSHkey-xxx* and that without this file I will not be able to log in to my ECS." If you have never created a key pair, click **View Key Pair** to create or import a key pair. And then, obtain a private key file. A key pair, also called an SSH key, consists of a public key and a private key. You can create an SSH key and download the private key for authenticating remote login. For security, a private key can only be downloaded once. Keep it secure. Use an SSH key in either of the following two methods: 1. Creating an SSH key: After you create an SSH key, a public key and a private key are generated. The public key is stored in the system, and the private key is stored in the local ECS. When you log in to an ECS, the public and private keys are used for authentication. 2. Importing an SSH key: If you have obtained the public and private keys, import the public key into the system. When you log in to an ECS, the public and private keys are used for authentication.
Hostname Prefix	Enter the prefix for the computer hostname of an ECS in the cluster.
Setting Advanced Options	Advanced function parameters of an MRS cluster. Select **Configure**. For details, see **Table 4-5**.

Table 4-5 (Optional) Advanced configuration information of the MRS cluster

Parameter	Description
Tag	For details, see **Adding a Tag to a Cluster/Node**.
Auto Scaling	Auto scaling can be configured only after you specify task node specifications in the **Configure Hardware** step by referring to **Configuring Auto Scaling Rules**.
Bootstrap Action	For details, see **Adding a Bootstrap Action**.
Agency	By binding an agency, ECSs or BMSs can manage some of your resources. Determine whether to configure an agency based on the actual service scenario. For example, you can configure an agency of the ECS type to automatically obtain the AK/SK to access OBS. For details, see **Configuring a Storage-Compute Decoupled Cluster (Agency)**. The **MRS_ECS_DEFAULT_AGENCY** agency has the OBSOperateAccess permission of OBS and the CESFullAccess (for users who have enabled fine-grained policies), CES Administrator, and KMS Administrator permissions in the region where the cluster is located.
Data Disk Encryption	Whether to encrypt data in the data disk mounted to the cluster. This function is disabled by default. To use this function, you must have the Security Administrator and KMS Administrator permissions. Keys used by encrypted data disks are provided by the Key Management Service (KMS) of the Data Encryption Workshop (DEW), secure and convenient. Therefore, you do not need to establish and maintain the key management infrastructure. Click **Data Disk Encryption** to enable or disable the data disk encryption function.
Data Disk Key ID	This parameter is displayed only when the **Data Disk Encryption** function is enabled. This parameter indicates the key ID corresponding to the selected key name.

Parameter	Description
Data Disk Key Name	This parameter is mandatory when the **Data Disk Encryption** function is enabled. Select the name of the key used to encrypt the data disk. By default, the default master key named **evs/default** is selected. You can select another master key from the drop-down list. If disks are encrypted using a CMK, which is then disabled or scheduled for deletion, the disks can no longer be read from or written to, and data on these disks may never be restored. Exercise caution when performing this operation. Click **View Key List** to enter a page where you can create and manage keys.
Alarm	If the alarm function is enabled, the cluster maintenance personnel can be notified in a timely manner to locate faults when the cluster runs abnormally or the system is faulty.
Rule Name	Name of the rule for sending alarm messages. The value can contain only digits, letters, hyphens (-), and underscores (_).
Topic Name	Select an existing topic or click **Create Topic** to create a topic. To deliver messages published to a topic, you need to add a subscriber to the topic. For details, see **Adding Subscriptions to a Topic**. A topic serves as a message sending channel, where publishers and subscribers can interact with each other.
Logging	Whether to collect logs when cluster creation fails. After the logging function is enabled, system logs and component run logs are automatically collected and saved to the OBS file system in scenarios such as cluster creation failures and scale-out or scale-in failures for O&M personnel to quickly locate faults. The log information is retained for a maximum of seven days.

Failed to Create a Cluster

If a cluster fails to be created, the failed task will be managed on the **Manage Failed Tasks** page. Choose **Clusters** > **Active Clusters**. Click to go to the **Manage Failed Tasks** page. In the **Task Status** column, hover your cursor over to view the failure cause. You can delete failed tasks by referring to **Viewing Failed MRS Tasks**.

Table 4-6 lists the error codes of MRS cluster creation failures.

Table 4-6 Error codes

Error Code	Description
MRS.101	Insufficient quota to meet your request. Contact customer service to increase the quota.
MRS.102	The token cannot be null or invalid. Try again later or contact the administrator.
MRS.103	Invalid request. Try again later or contact the administrator.
MRS.104	Insufficient resources. Try again later or contact the administrator.
MRS.105	Insufficient IP addresses in the existing subnet. Try again later or contact the administrator.
MRS.201	Failed due to an ECS error. Try again later or contact the administrator.
MRS.202	Failed due to an IAM error. Try again later or contact the administrator.
MRS.203	Failed due to a VPC error. Try again later or contact the administrator.
MRS.400	MRS system error. Try again later or contact the administrator.

4.4 Configuring Custom Topology

The analysis cluster, streaming cluster, and hybrid cluster provided by MRS use fixed templates to deploy cluster processes. Therefore, you cannot customize service processes on management nodes and control nodes. If you want to customize the cluster deployment, set **Cluster Type** to **Custom** when creating a cluster. In this way, you can customize the deployment mode of process instances on the management nodes and control nodes in the cluster.

A custom cluster provides the following functions:

- Separated deployment of the management and control roles: The management role and control role are deployed on different Master nodes.
- Co-deployment of the management and control roles: The management and control roles are co-deployed on the Master node.
- ZooKeeper is deployed on an independent node to improve reliability.
- Components are deployed separately to avoid resource contention.

Roles in an MRS cluster:

- Management Node (MN): is the node to install Manager (the management system of the MRS cluster). It provides a unified access entry. Manager centrally manages nodes and services deployed in the cluster.
- Control Node (CN): controls and monitors how data nodes store and receive data, and send process status, and provides other public functions. Control

nodes of MRS include HMaster, HiveServer, ResourceManager, NameNode, JournalNode, and SlapdServer.

- Data Node (DN): A data node executes the instructions sent by the management node, reports task status, stores data, and provides other public functions. Data nodes of MRS include DataNode, RegionServer, and NodeManager.

Customizing a Cluster

Step 1 Click the **Custom Config** tab.

Step 2 Configure basic cluster information. For details about the parameters, see **Software Configurations**.

- **Region**: Retain the default value.
- **Cluster Name**: You can use the default name. However, you are advised to include a project name abbreviation or date for consolidated memory and easy distinguishing, for example, **mrs_20180321**.
- **Cluster Version**: Select the latest version, which is the default value. (The components provided by a cluster vary according to the cluster version. Select a cluster version based on site requirements.)
- **Cluster Type**: Select **Custom** and select components as required.

Step 3 Click **Next**. Configure hardware information.

- **AZ**: Retain the default value.
- **VPC**: Retain the default value. If there is no available VPC, click **View VPC** to access the VPC console and create a new VPC.
- **Subnet**: Retain the default value.
- **Security Group**: Select **Auto create**.
- **EIP**: Select **Bind later**.
- **Common Node**: For details, see **Custom Cluster Template Description**.
- **Node Count**: Adjust the number of cluster instances based on the service volume. For details, see **Table 4-8**.
- **Instance Specifications**: Click  to configure the instance specifications, system disk and data disk storage types, and storage space.
- **Topology Adjustment**: If the deployment mode in the **Common Node** does not meet the requirements, you need to manually install some instances that are not deployed by default, or you need to manually install some instances, set **Topology Adjustment** to **Enable** and adjust the instance deployment mode based on service requirements. For details, see **Topology Adjustment for a Custom Cluster**.

Step 4 Click **Next** and set advanced options.

For details about the parameters, see **Advanced Options**.

Step 5 Click **Create Now**.

If Kerberos authentication is enabled for a cluster, check whether Kerberos authentication is required. If yes, click **Continue**. If no, click **Back** to disable Kerberos authentication and then create a cluster.

Step 6 Click **Back to Cluster List** to view the cluster status.

It takes some time to create a cluster. The initial status of the cluster is **Starting**. After the cluster has been created successfully, the cluster status becomes **Running**.

----End

Custom Cluster Template Description

Table 4-7 Common templates for custom clusters

Common Node	Description	Node Range
Compact	The management role and control role are deployed on the Master node, and data instances are deployed in the same node group. This deployment mode applies to scenarios where the number of control nodes is less than 100, reducing costs.	• The number of Master nodes is greater than or equal to 3 and less than or equal to 11. • The total number of node groups is less than or equal to 10, and the total number of nodes in non-Master node groups is less than or equal to 10,000.
OMS-separate	The management role and control role are deployed on different Master nodes, and data instances are deployed in the same node group. This deployment mode is applicable to a cluster with 100 to 500 nodes and delivers better performance in high-concurrency load scenarios.	• The number of Master nodes is greater than or equal to 5 and less than or equal to 11. • The total number of node groups is less than or equal to 10, and the total number of nodes in non-Master node groups is less than or equal to 10,000.
Full-size	The management role and control role are deployed on different Master nodes, and data instances are deployed in different node groups. This deployment mode is applicable to a cluster with more than 500 nodes. Components can be deployed separately, which can be used for a larger cluster scale.	• The number of Master nodes is greater than or equal to 9 and less than or equal to 11. • The total number of node groups is less than or equal to 10, and the total number of nodes in non-Master node groups is less than or equal to 10,000.

Table 4-8 Node deployment scheme of a customized MRS cluster

Node Deployment Principle		Applicable Scenario	Networking Rule
Management nodes, control nodes, and data nodes are deployed separately. (This scheme requires at least eight nodes.)	MN × 2 + CN × 9 + DN × n	(Recommended) This scheme is used when the number of data nodes is 500–2000.	• If the number of nodes in a cluster exceeds 200, the nodes are distributed to different subnets and the subnets are interconnected with each other in Layer 3 using core switches. Each subnet can contain a maximum of 200 nodes and the allocation of nodes to different subnets must be balanced. • If the number of nodes is less than 200, the nodes in the cluster are deployed in the same subnet and the nodes are interconnected with each other in Layer 2 using aggregation switches.
	MN × 2 + CN × 5 + DN × n	(Recommended) This scheme is used when the number of data nodes is 100–500.	
	MN × 2 + CN × 3 + DN × n	(Recommended) This scheme is used when the number of data nodes is 30–100.	
The management nodes and control nodes are deployed together, and the data nodes are deployed separately.	(MN+CN) × 3 + DN × n	(Recommended) This scheme is used when the number of data nodes is 3–30.	Nodes in the cluster are deployed in the same subnet and are interconnected with each other at Layer 2 through aggregation switches.

Node Deployment Principle	Applicable Scenario	Networking Rule
The management nodes, control nodes, and data nodes are deployed together.	• This scheme is applicable to a cluster having fewer than 6 nodes. • This scheme requires at least three nodes. **NOTE** This template is not recommended in the production environment or commercial environment. • If management, control, and data nodes are co-deployed, cluster performance and reliability are greatly affected. • If the number of nodes meet the requirements, deploy data nodes separately. • If the number of nodes is insufficient to support separately deployed data nodes, use the dual-plane networking mode for this scenario. The traffic of the management network is isolated from that of the service network to prevent excessive data volumes on the service plane, ensuring correct delivery of management operations.	Nodes in the cluster are deployed in the same subnet and are interconnected with each other at Layer 2 through aggregation switches.

Topology Adjustment for a Custom Cluster

Table 4-9 Topology adjustment

Service	Dependency	Role	Role Deployment Suggestions	Description
OMSServer	-	OMSServer	This role can be deployed it on the Master node and cannot be modified.	-

Service	Dependency	Role	Role Deployment Suggestions	Description
ClickHouse	Depends on ZooKeeper.	CHS (ClickHouseServer)	This role can be deployed on all nodes. Number of role instances to be deployed: an even number ranging from 2 to 256	A non-Master node group with this role assigned is considered as a Core node.
		CLB (ClickHouseBalancer)	This role can be deployed on all nodes. Number of role instances to be deployed: 2 to 256	-
ZooKeeper	-	QP(quorumpeer)	This role can be deployed on the Master node only. Number of role instances to be deployed: 3 to 9, with the step size of 2	-
Hadoop	Depends on ZooKeeper.	NN(NameNode)	This role can be deployed on the Master node only. Number of role instances to be deployed: 2	-
		HFS (HttpFS)	This role can be deployed on the Master node only. Number of role instances to be deployed: 0 to 10	-
		JN(JournalNode)	This role can be deployed on the Master node only. Number of role instances to be deployed: 3 to 60, with the step size of 2	-

Service	Dependency	Role	Role Deployment Suggestions	Description
		DN(DataNode)	This role can be deployed on all nodes. Number of role instances to be deployed: 3 to 10,000	A non-Master node group with this role assigned is considered as a Core node.
		RM(ResourceManager)	This role can be deployed on the Master node only. Number of role instances to be deployed: 2	-
		NM(NodeManager)	This role can be deployed on all nodes. Number of role instances to be deployed: 3 to 10,000	-
		JHS(JobHistoryServer)	This role can be deployed on the Master node only. Number of role instances to be deployed: 1 to 2	-
		TLS(TimelineServer)	This role can be deployed on the Master node only. Number of role instances to be deployed: 0 to 1	-
Spark	• Depends on Hadoop. • Depends on Hive. • Depends on ZooKeeper.	JS(JDBCServer)	This role can be deployed on the Master node only. Number of role instances to be deployed: 2 to 10	-

Service	Dependency	Role	Role Deployment Suggestions	Description
		JH(JobHistory)	This role can be deployed on the Master node only. Number of role instances to be deployed: 2	-
		SR(Spark Resource)	This role can be deployed on the Master node only. Number of role instances to be deployed: 2 to 50	-
		IS(IndexServer)	(Optional) This role can be deployed on the Master node only. Number of role instances to be deployed: 0 to 2, with the step size of 2	-
HBase	Depends on Hadoop.	HM(HMaster)	This role can be deployed on the Master node only. Number of role instances to be deployed: 2	-
		TS(ThriftServer)	This role can be deployed on all nodes. Number of role instances to be deployed: 0 to 10,000	-
		RT(RESTServer)	This role can be deployed on all nodes. Number of role instances to be deployed: 0 to 10,000	-

Service	Dependency	Role	Role Deployment Suggestions	Description
		RS(RegionServer)	This role can be deployed on all nodes. Number of role instances to be deployed: 3 to 10,000	-
		TS1(Thrift1Server)	This role can be deployed on all nodes. Number of role instances to be deployed: 0 to 10,000	If the Hue service is installed in a cluster and HBase needs to be used on the Hue web UI, install this instance for the HBase service.
Hive	• Depends on Hadoop. • Depends on DBService.	MS(MetaStore)	This role can be deployed on the Master node only. Number of role instances to be deployed: 2 to 10	-
		WH(WebHCat)	This role can be deployed on the Master node only. Number of role instances to be deployed: 1 to 10	-
		HS(HiveServer)	This role can be deployed on the Master node only. Number of role instances to be deployed: 2 to 80	-
Hue	Depends on DBService.	H(Hue)	This role can be deployed on the Master node only. Number of role instances to be deployed: 2	-

Service	Dependency	Role	Role Deployment Suggestions	Description
Kafka	Depends on ZooKeeper.	B(Broker)	This role can be deployed on all nodes. Number of role instances to be deployed: 3 to 10,000	-
Flume	-	MS(MonitorServer)	This role can be deployed on the Master node only. Number of role instances to be deployed: 1 to 2	-
		F(Flume)	This role can be deployed on all nodes. Number of role instances to be deployed: 1 to 10,000	A non-Master node group with this role assigned is considered as a Core node.
Tez	• Depends on Hadoop. • Depends on DBService. • Depends on ZooKeeper.	TUI(TezUI)	This role can be deployed on the Master node only. Number of role instances to be deployed: 1 to 2	-

Service	Dependency	Role	Role Deployment Suggestions	Description
Flink	• Depends on ZooKeeper. • Depends on KrbServer. • Depends on DBService. • Depends on Hadoop.	FR(FlinkResource)	This role can be deployed on all nodes. Number of role instances to be deployed: 1 to 10,000	-
		FS(FlinkServer)	This role can be deployed on all nodes. Number of role instances to be deployed: 0 to 2	-
Oozie	• Depends on Hadoop. • Depends on DBService. • Depends on ZooKeeper.	O(oozie)	This role can be deployed on the Master node only. Number of role instances to be deployed: 2	-
Ranger	Depends on DBService.	RA(RangerAdmin)	This role can be deployed on the Master node only. Number of role instances to be deployed: 1 to 2	-
		USC(UserSync)	This role can be deployed on the Master node only. Number of role instances to be deployed: 1	-

Service	Dependency	Role	Role Deployment Suggestions	Description
		TSC (TagSync)	This role can be deployed on all nodes. Number of role instances to be deployed: 0 to 1	-
HetuEngine	• Depends on Hadoop. • Depends on DBService. • Depends on Hive. • Depends on ZooKeeper. • Depends on KrbServer. • Depends on Yarn. • Depends on HDFS.	HSB(HSBroker)	This role can be deployed on all nodes. Number of role instances to be deployed: 2 to 50	-
		HSC(HSConsole)	This role can be deployed on all nodes. Number of role instances to be deployed: 2	-
		HSF(HSFabric)	This role can be deployed on all nodes. Number of role instances to be deployed: 0 to 50	-
		QAS	This role can be deployed on all nodes. Number of role instances to be deployed: 0 to 2	-
IoTDB	Depends on KrbServer.	ConfigNode (CN)	This role can be deployed on Master nodes only. Number of role instances to be deployed: 3 to 9, with the step size of 2	-

Service	Dependency	Role	Role Deployment Suggestions	Description
		IoTDBServer (IoTDBS)	This role can be deployed on all nodes. Number of role instances to be deployed: 3 to 256	-
CDL	• Depends on DBService. • Depends on HDFS. • Depends on Hive. • Depends on KrbServer. • Depends on Kafka. • Depends on Spark. • Depends on ZooKeeper. • Depends on Yarn.	CDLConnector (CC)	This role can be deployed on all nodes. Number of role instances to be deployed: 1 to 256	-
		CDLService (CS)	This role can be deployed on all nodes. Number of role instances to be deployed: 1 to 2	-

4.5 Adding a Tag to a Cluster/Node

Tags are used to identify clusters/nodes. Adding tags to clusters/nodes can help you identify and manage your resources.

- Cluster tags: You can add up to 10 tags to a cluster during cluster creation or add them on the details page of a created cluster. Updating a cluster tag will synchronize the tag to all nodes in the cluster.

- Node tags: You can use the default tag or add tags to nodes in an MRS cluster when you configure an auto scaling policy. Node tags take the tag quotas. You can view the tags of a node in the **Nodes** tab on MRS console.
- Default tags: An MRS cluster contains multiple nodes, and each node is an ECS and contains EVS disks. After the default tag is enabled, the system automatically creates a cluster tag and a tag for each node. The default tag is automatically synchronized to the corresponding ECS or EVS instances.

  To view node tags, go to the **Nodes** tab on the MRS console, and move the cursor to the tag icon of a node in the node list.

  NOTE

  - MRS tag updates are synchronized to the ECSs or EVS disks in the cluster. However, if you modify MRS cluster tags on the ECS or EVS console, the modification will not be synchronized to MRS. To ensure tag consistency, do not modify MRS cluster tags on the ECS or EVS console.
  - You can add a maximum of 10 tags to a cluster. If the number of tags of a node in the cluster reaches the upper limit, no more tags can be added to the cluster.
  - If default tags are enabled, a default tag is added to the cluster and each node, which takes two quotas. That is, a maximum of 10 tags can be added by default. In this case, a maximum of eight more tags can still be added.

If your organization has configured tag strategies for MRS, add tags to clusters/nodes based on the strategies. If a tag does not comply with the tag strategies, the cluster/node may be failed to be created. Contact the organization administrator to learn more about the tag strategies.

A tag consists of a tag key and a tag value. **Table 4-10** provides tag key and value requirements.

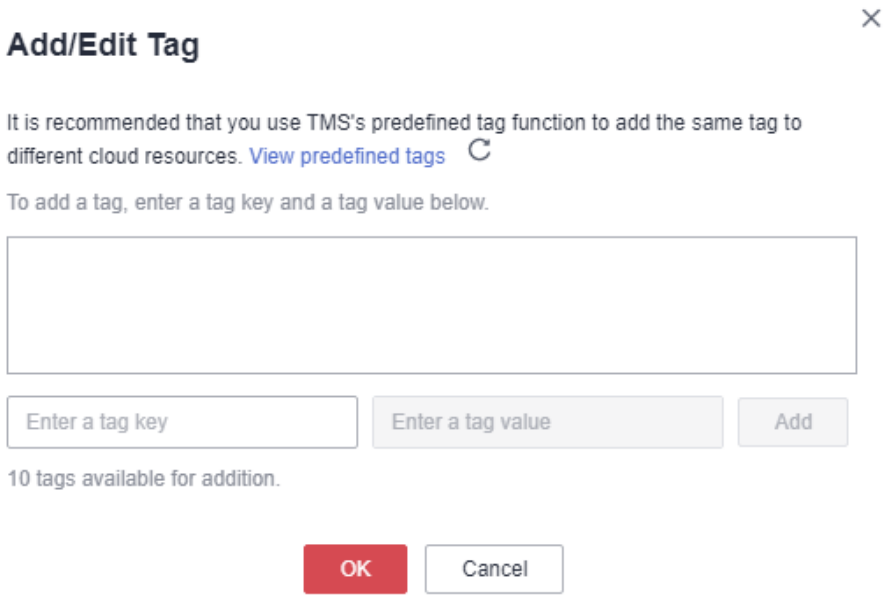
Table 4-10 Tag key and value requirements

Parameter	Requirement	Example
Key	A tag key cannot be left blank. A tag key must be unique in a cluster. A tag key contains a maximum of 36 characters. A tag value cannot contain special characters (=*<>\,|/) or start or end with spaces.	Organization

Parameter	Requirement	Example
Value	A tag value contains a maximum of 43 characters. A tag value cannot contain special characters (=*<>\,|/) or start or end with spaces. This parameter can be left blank.	Apache

Adding Tags to a Cluster

- Adding cluster tags during cluster creation
  a. Log in to the MRS console.
  b. Click **Create Cluster**. The page for creating a cluster is displayed.
  c. Click the **Custom Config** tab.
  d. Configure the cluster software and hardware by referring to **Creating a Custom Cluster**.
  e. Select **Configure** on the right of **Set Advanced Options** and enter the key and value of a new tag.
- Adding tags to an existing cluster
  a. Log in to the MRS management console.
  b. In the navigation pane on the left, choose **Clusters** > **Active Clusters**. Click the name of a running cluster. The basic information page of the cluster is displayed.
  c. Click the **Tags** tab.
  d. Click **Add/Edit Tag**. If this is your first time adding a tag, click **Add Tag**. In the displayed dialog box, enter the key and value of a tag, and click **Add**.



NOTE

You can also add cluster tags by enabling default tags. All nodes will be tagged with the cluster ID and node IDs, which takes two quotas.

e. Click **OK**.

Adding Tags to a Node

- Node tags are automatically added when a default tag is added to a cluster. For details, see **Adding tags to an existing cluster**.
- Adding node tags for auto scaling

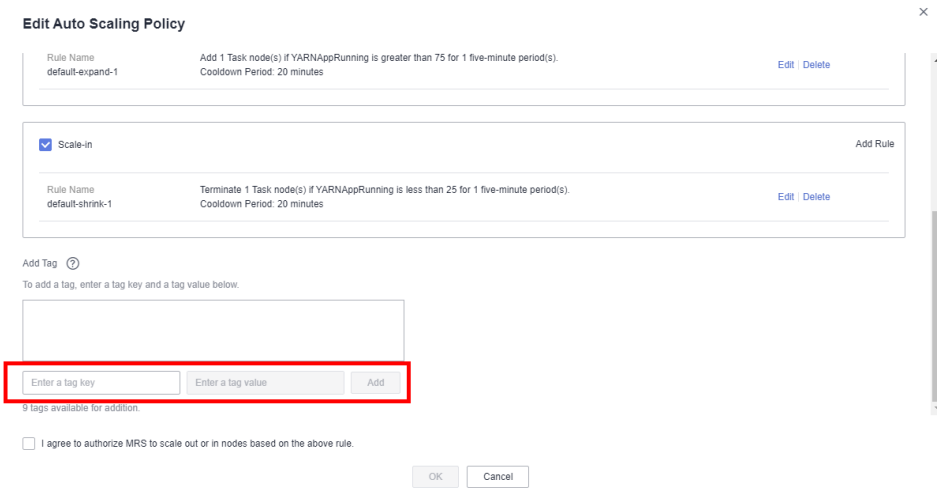
  If you add a tag when configuring an auto scaling policy, MRS automatically adds the tag to the new nodes and synchronizes the tag to the ECSs and EVS disks.

  a. Log in to the MRS management console.

  b. In the navigation pane on the left, choose **Clusters** > **Active Clusters**. Click the name of a running cluster. The basic information page of the cluster is displayed.

  c. On the page that is displayed, click the **Auto Scaling** tab.

  d. Click **Edit** on the right of an existing auto scaling policy. In the displayed dialog box, enter the key and value of the tag you want to add, and click **Add**.



NOTE

- You need to enable the auto scaling policy and configure scale-out rules. Otherwise, the node tags will not take effect.
- If tag quotas are insufficient, delete the cluster tag or modify existing a tag of the auto scaling policy, and then enable the policy.
- Tags cannot be added to auto scaling policies of resource pools.

e. Click **OK**.

Searching for Target Clusters by Tags

On the **Active Clusters** page, search for the target cluster by tag key or tag value.

1. Log in to the MRS console.
2. In the upper right corner of the **Active Clusters** page, click **Search by Tag** to access the search page.
3. Enter the tag of the cluster to be searched.

   You can select a tag key or tag value from their drop-down lists. When the tag key or tag value is exactly matched, the system can automatically locate the target cluster. If you enter multiple tags, their intersections are used to search for the cluster.
4. Click **Search**.

   The system searches for the target cluster by tag key or value.

Managing Tags

You can view, add, and delete tags on the **Tags** tab page of the cluster.

1. Log in to the MRS console.
2. On the **Active Clusters** page, click the name of a cluster for which you want to manage tags.

   The cluster details page is displayed.
3. Click the **Tags** tab and view, add, and delete tags on the tab page.
   - View

     On the **Tags** tab page, you can view details about tags of the cluster, including the number of tags and the key and value of each tag.
   - Add

     Click **Add/Edit Tag** in the upper left corner. In the displayed **Add/Edit Tag** dialog box, enter the key and value of the tag to be added, and click **OK**.
   - Delete

     Locate the row that contains the tag you want to delete and click **Delete** in the **Operation** column. In the displayed **Delete Tag** dialog box, and click **Yes**.

4.6 Communication Security Authorization

MRS clusters provision, manage, and use big data components through the management console. Big data components are deployed in a user's VPC. If the MRS management console needs to directly access big data components deployed in the user's VPC, you need to enable the corresponding security group rules after you have obtained user authorization. This authorization process is called secure communications.

If the secure communications function is not enabled, MRS clusters cannot be created. If you disable the communication after a cluster is created, the cluster status will be **Network channel is not authorized** and the following functions will be affected:

- Functions, such as big data component installation, cluster scale-out/scale-in, and Master node specification upgrade, are unavailable.

- The cluster running status, alarms, and events cannot be monitored.
- The node management, component management, alarm management, file management, job management, patch management, and tenant management functions on the cluster details page are unavailable.
- The Manager page and the website of each component cannot be accessed.

After the secure communications function is enabled again, the cluster status is restored to **Running**, and the preceding functions become available. For details, see **Enabling Secure Communications for Clusters with This Function Disabled**.

If the security group rules authorized in the cluster are insufficient for you to provision, manage, and use big data components, is displayed on the right of **Secure Communications**. In this case, click **Update** to update the security group rules. For details, see **Update**.

Enabling Secure Communications During Cluster Creation

Step 1 Log in to the MRS console.

Step 2 Click **Create Cluster**. The page for creating a cluster is displayed.

Step 3 On the displayed page, select **Quick Config**.

Step 4 Configure cluster information by referring to **Quick Configuration** or **Creating a Custom Cluster**.

Step 5 Select the check box for **Secure Communications**.

Step 6 Click **Create Now**.

If Kerberos authentication is enabled for a cluster, check whether Kerberos authentication is required. If yes, click **Continue**. If no, click **Back** to disable Kerberos authentication and then create a cluster.

----End

Disabling Secure Communications After a Cluster Is Created

Step 1 Log in to the MRS console.

Step 2 In the active cluster list, click the name of the cluster for which you want to disable secure communications.

The cluster details page is displayed.

Step 3 Click the switch on the right of **Secure Communications** to disable authorization. In the dialog box that is displayed, click **OK**.

After the authorization is disabled, the cluster status changes to **Network channel unauthorized**, and some functions of the cluster are unavailable. Exercise caution when performing this operation.

----End

Enabling Secure Communications for Clusters with This Function Disabled

Step 1 Log in to the MRS console.

Step 2 In the active cluster list, click the name of the cluster for which you want to enable secure communications.

The cluster details page is displayed.

Step 3 Click the switch on the right of **Secure Communications** to enable the function.

After the function is enabled, the cluster status changes to **Running**.

----End

Update

If the security group rules authorized in the cluster are insufficient for you to provision, manage, and use big data components, is displayed on the right of **Secure Communications**. In this case, click **Update** to update the security group rules. For details, see **Update**.

Step 1 Log in to the MRS console.

Step 2 In the active cluster list, click the name of the cluster for which you want to update secure communications.

The cluster details page is displayed.

Step 3 Click **Update** on the right of **Secure Communications**.

Figure 4-1 Update

Step 4 Click **OK**.

----End

4.7 Configuring Auto Scaling Rules

4.7.1 Overview

In big data application scenarios, especially real-time data analysis and processing, the number of cluster nodes needs to be dynamically adjusted according to data volume changes to provide the required number of resources. The auto scaling function of MRS enables the task nodes of a cluster to be automatically scaled to match cluster loads. If the data volume changes periodically, you can configure an auto scaling rule so that the number of task nodes can be automatically adjusted in a fixed period of time before the data volume changes.

- Auto scaling rules: You can increase or decrease task nodes based on real-time cluster loads. Auto scaling will be triggered with a certain delay when the data volume changes.

- Resource plans: Set the task node quantity based on the time range. If the data volume changes periodically, you can create resource plans to resize the cluster before the data volume changes, thereby avoiding delays in increasing or decreasing resources.

You can configure either auto scaling rules or resource plans or both to trigger auto scaling. Configuring both resource plans and auto scaling rules improves the cluster node scalability to cope with occasionally unexpected data volume peaks.

In some service scenarios, resources need to be reallocated or service logic needs to be modified after cluster scale-out or scale-in. If you manually scale out or scale in a cluster, you can log in to cluster nodes to reallocate resources or modify service logic. If you use auto scaling, MRS enables you to customize automation scripts for resource reallocation and service logic modification. Automation scripts can be executed before and after auto scaling and automatically adapt to service load changes, all of which eliminates manual operations. In addition, automation scripts can be fully customized and executed at various moments, meeting your personalized requirements and improving auto scaling flexibility.

- Auto scaling rules:
  - You can set a maximum of five rules for scaling out or in a cluster, respectively.
  - The system determines the scale-out and then scale-in based on your configuration sequence. Important policies take precedence over other policies to prevent repeated triggering when the expected effect cannot be achieved after a scale-out or scale-in.
  - Comparison factors include greater than, greater than or equal to, less than, and less than or equal to.
  - Cluster scale-out or scale-in can be triggered only after the configured metric threshold is reached for consecutive 5*n* (the default value of *n* is 1) minutes.
  - After each scale-out or scale-in, there is a cooling duration that is greater than 0 and lasts 20 minutes by defaults.
  - In each cluster scale-out or scale-in, at least one node and at most 100 nodes can be added or reduced.
  - The number of task nodes in a cluster is limited to the default number of nodes configured by users or the node quantity range in the resource plan that takes effect in the current time period. The node quantity range in the resource plan that takes effect in the current time period has a higher priority.
- Resource plans (setting the number of Task nodes by time range):
  - You can specify a Task node range (minimum number to maximum number) in a time range. If the number of Task nodes is beyond the Task node range in a resource plan, the system triggers cluster scale-out or scale-in.
  - You can set a maximum of five resource plans for a cluster.
  - A resource plan cycle is by day. The start time and end time can be set to any time point between 00:00 and 23:59. The start time must be at least 30 minutes earlier than the end time. Time ranges configured for different resource plans cannot overlap.

  - After a resource plan triggers cluster scale-out or scale-in, there is 10-minute cooling duration. Auto scaling will not be triggered again within the cooling time.
  - When a resource plan is enabled, the number of Task nodes in the cluster is limited to the default node range configured by you in other time periods except the time period configured in the resource plan.
- Automation scripts:
  - You can set an automation script so that it can automatically run on cluster nodes when auto scaling is triggered.
  - You can set a maximum number of 10 automation scripts for a cluster.
  - You can specify an automation script to be executed on one or more types of nodes.
  - Automation scripts can be executed before or after scale-out or scale-in.
  - Before using automation scripts, upload them to a cluster VM or OBS file system in the same region as the cluster. The automation scripts uploaded to the cluster VM can be executed only on the existing nodes. If you want to make the automation scripts run on the new nodes, upload them to the OBS file system.

4.7.2 Configuring Auto Scaling During Cluster Creation

When you create a cluster, you can configure the auto scaling function in advanced configuration parameters.

NOTE

Auto scaling policies can be configured during cluster creation only for analysis, streaming, and hybrid clusters.

Procedure

Step 1 Log in to the MRS management console.

Step 2 When you create a cluster containing task nodes, configure the cluster software and hardware information by referring to **Creating a Custom Cluster**. Then, on the **Set Advanced Options** page, enable **Analysis Task** and configure or modify auto scaling rules and resource plans.

NOTE

You can configure the auto scaling rules by referring to the following scenarios:

- **Scenario 1: Using Auto Scaling Rules Alone**
- **Scenario 2: Using Resource Plans Alone**
- **Scenario 3: Using Both Auto Scaling Rules and Resource Plans**

----End

4.7.3 Creating an Auto Scaling Policy for an Existing Cluster

After a cluster is created, you can configure rules for the task node group in a cluster by node group or resource pool.

The node group policy and resource pool policy are mutually exclusive. You can configure either of them as needed.

Item	By Node Group	By Resource Pool
Auto scaling object	All nodes in the task node group	Task nodes in the resource pool specified by an auto scaling policy
Resource pool ownership of added nodes	Default resource pool	Resource pool specified by the auto scaling policy
Scale-in object	Random scale-in of nodes in the task node group	Random scale-in of nodes in a resource pool specified by an auto scaling policy

Prerequisites

- A task node group has been configured by referring to **Adding a Task Node**.
- A resource pool has been added by referring to **Creating a Resource Pool** if you plan to configure auto scaling policies by resource pool.

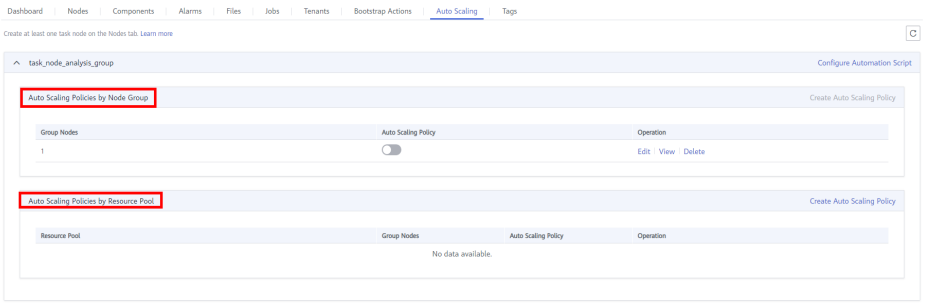
Procedure

Step 1 Log in to the MRS management console.

Step 2 Choose **Clusters** > **Active Clusters**. In the cluster list, select a running cluster to access its details page.

Step 3 On the page that is displayed, click the **Auto Scaling** tab.

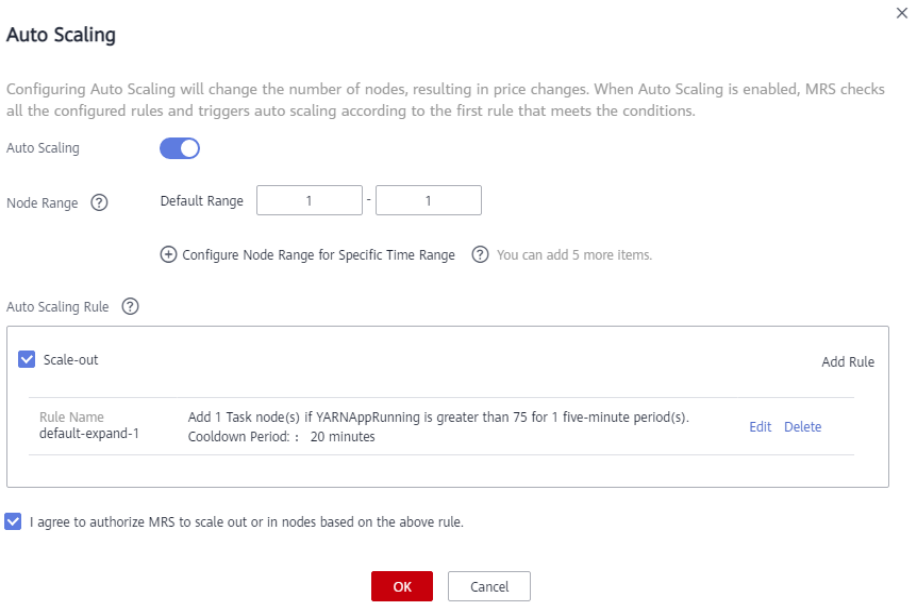
You can configure policies by resource pool or node group as needed.



NOTE

- Auto scaling policies of different node groups are mutually exclusive. That is, you can enable auto scaling policies only for one node group.

Step 4 Click **Create Auto Scaling Policy** to create an auto scaling policy.



NOTE

You can configure the auto scaling rules by referring to the following scenarios:

- **Scenario 1: Using Auto Scaling Rules Alone**
- **Scenario 2: Using Resource Plans Alone**
- **Scenario 3: Using Both Auto Scaling Rules and Resource Plans**

----End

4.7.4 Scenario 1: Using Auto Scaling Rules Alone

Scenario where only auto scaling rules are configured: The number of nodes needs to be dynamically adjusted based on the YARN resource usage. When the available YARN memory is less than 20%, five nodes need to be added. When the available YARN memory is greater than 70%, five nodes need to be reduced. The number of nodes in a task node group ranges from 1 to 10.

Procedure

Step 1 Go to the **Auto Scaling** page to configure auto scaling rules.

- Configure the **Default Range** parameter.

  Enter a task node range, in which auto scaling is performed. This constraint applies to all scale-in and scale-out rules. The maximum value range allowed is 0 to 500.

  The value range in this example is 1 to 10.

- Configure an auto scaling rule.

  To enable **Auto Scaling**, you must configure a scale-out or scale-in rule.

  a. Select **Scale-Out** or **Scale-In**.

  b. Click **Add Rule**.

c. Configure **Rule Name**, **If**, **Last For**, **Add**, and **Cooldown Period**. For details about auto scaling metrics, see **Configuring Auto Scaling Metrics**.

d. Click **OK**.

You can view, edit, or delete the rules you configured in the **Scale-out** or **Scale-in** area on the **Auto Scaling** page. You can click **Add Rule** to configure multiple rules.

Step 2 Click **OK**.

NOTE

If you want to configure an auto scaling rule for an existing cluster, select **I agree to authorize MRS to scale out or in nodes based on the above rule**.

----End

4.7.5 Scenario 2: Using Resource Plans Alone

If the data volume changes regularly every day and you want to scale out or scale in a cluster before the data volume changes, you can create resource plans to adjust the number of Task nodes as planned in the specified time range.

Background

A real-time processing service sees a sharp increase in data volume from 7:00 to 13:00 on Monday, Tuesday, and Saturday. Assume that an MRS streaming cluster is used to process the service data. Five task nodes are required from 7:00 to 13:00 on Monday, Tuesday, and Saturday, while only two are required at other time.

Procedure

Step 1 Go to the **Auto Scaling** page to configure a resource plan.

Step 2 For example, the **Default Range** of node quantity is set to **2-2**, indicating that the number of task nodes is fixed to 2 except the time range specified in the resource plan.

Step 3 Click **Configure Node Range for Specific Time Range** under **Default Range** or **Add Resource Plan**.

Step 4 Configure **Effective On**, **Time Range**, and **Node Range**.

For example, set **Effective On** to **Monday**, **Tuesday**, and **Saturday**, **Time Range** to **07:00-13:00**, and **Node Range** to **5-5**. This indicates that the number of task nodes is fixed at 5 from 07:00 to 13:00.

You can click **Configure Node Range for Specific Time Range** to configure multiple resource plans.

NOTE

- **Effective On** is set to **Daily** by default. You can also select one or multiple days from Monday to Sunday.
- If you do not set **Node Range**, its default value will be used.
- If you set both **Node Range** and **Time Range**, the node range you set will be used during the time range you set, and the default node range will be used beyond the time range you set. If the time is not within the configured time range, the default range is used.

----End

4.7.6 Scenario 3: Using Both Auto Scaling Rules and Resource Plans

If the data volume is not stable and the expected fluctuation may occur, the fixed Task node range cannot guarantee that the requirements in some service scenarios are met. In this case, it is necessary to adjust the number of Task nodes based on the real-time loads and resource plans.

Background

A real-time processing service sees an unstable increase in data volume from 7:00 to 13:00 on Monday, Tuesday, and Saturday. For example, 5 to 8 task nodes are required from 7:00 to 13:00 on Monday, Tuesday, and Saturday, and 2 to 4 are required beyond this period. Therefore, you can set an auto scaling rule based on a resource plan. When the data volume exceeds the expected value, the number of Task nodes can be adjusted if resource loads change, without exceeding the node range specified in the resource plan. When a resource plan is triggered, the number of nodes is adjusted within the specified node range with minimum affect. That is, increase nodes to the upper limit and decrease nodes to the lower limit.

Procedure

Step 1 Go to the **Auto Scaling** page to configure auto scaling rules.

- **Default Range**

  Enter a task node range, in which auto scaling is performed. This constraint applies to all scale-in and scale-out rules.

  For example, this parameter is set to **2-4** in this scenario.

- **Auto Scaling**

  To enable **Auto Scaling**, you must configure a scale-out or scale-in rule.

  a. Select **Scale-Out** or **Scale-In**.

  b. Click **Add Rule**. The **Add Rule** page is displayed.

  c. Configure the **Rule Name**, **If**, **Last for**, **Add**, and **Cooldown Period** parameters.

  d. Click **OK**.

  You can view, edit, or delete the rules you configured in the **Scale-out** or **Scale-in** area on the **Auto Scaling** page.

Step 2 Configure a resource plan.

1. Click **Configure Node Range for Specific Time Range** under **Default Range** or **Add Resource Plan**.
2. Configure **Effective On**, **Time Range**, and **Node Range**.

   For example, set **Effective On** to **Monday**, **Tuesday**, and **Saturday**, **Time Range** to **07:00-13:00**, and **Node Range** to **5-8**.

   You can click **Configure Node Range for Specific Time Range** or **Add Resource Plan** to configure multiple resource plans.

   NOTE

   - **Effective On** is set to **Daily** by default. You can also select one or multiple days from Monday to Sunday.
   - If you do not set **Node Range**, its default value will be used.
   - If you set both **Node Range** and **Time Range**, the node range you set will be used during the time range you set, and the default node range will be used beyond the time range you set. If the time is not within the configured time range, the default range is used.

----End

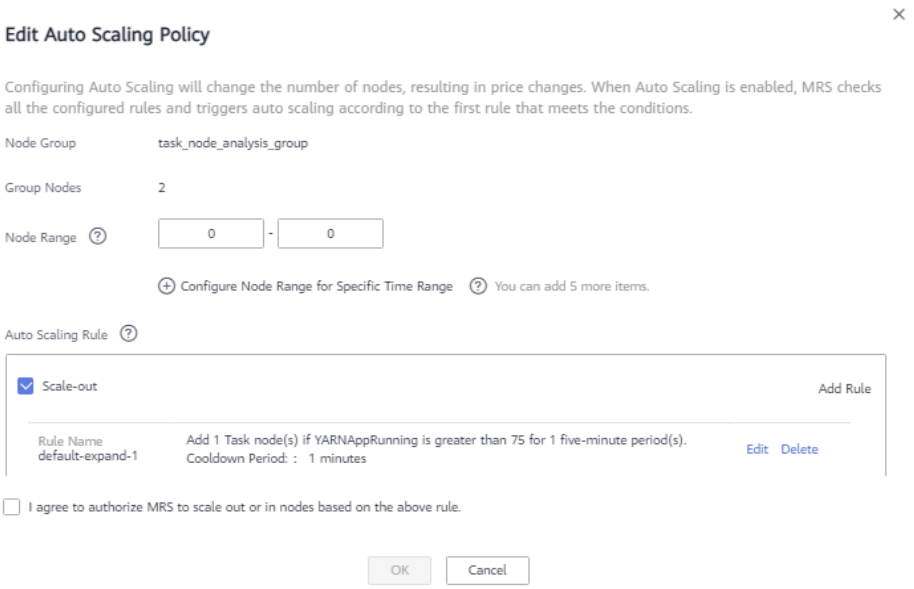
4.7.7 Modifying an Auto Scaling Policy

Step 1 Log in to the MRS management console.

Step 2 Choose **Clusters** > **Active Clusters**. In the cluster list, select a running cluster to access its details page.

Step 3 Click the **Auto Scaling** tab.

Step 4 Click **Edit** on the right of the target auto scaling policy.



----End

4.7.8 Deleting an Auto Scaling Policy

Step 1 Log in to the MRS management console.

Step 2 Choose **Clusters** > **Active Clusters**. In the cluster list, select a running cluster to access its details page.

Step 3 Click the **Auto Scaling** tab.

Step 4 Click **Delete** on the right of an existing AS policy.

----End

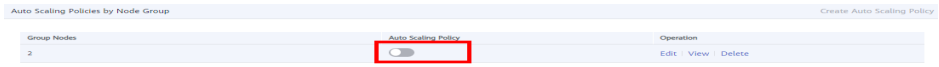
4.7.9 Enabling or Disabling an Auto Scaling Policy

Step 1 Log in to the MRS management console.

Step 2 Choose **Clusters** > **Active Clusters**. In the cluster list, select a running cluster to access its details page.

Step 3 Click the **Auto Scaling** tab.

Step 4 Toggle **Auto Scaling Policy** on or off to enable or disable an auto scaling policy.



----End

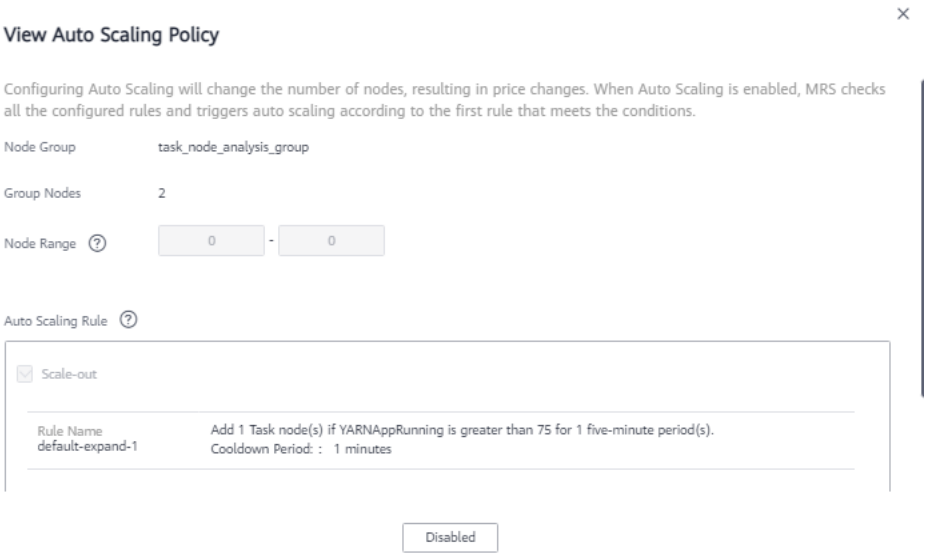
4.7.10 Viewing an Auto Scaling Policy

Step 1 Log in to the MRS management console.

Step 2 Choose **Clusters** > **Active Clusters**. In the cluster list, select a running cluster to access its details page.

Step 3 Click the **Auto Scaling** tab.

Step 4 Click **View** on the right of the target auto scaling policy to view it.



----End

4.7.11 Configuring Automation Scripts

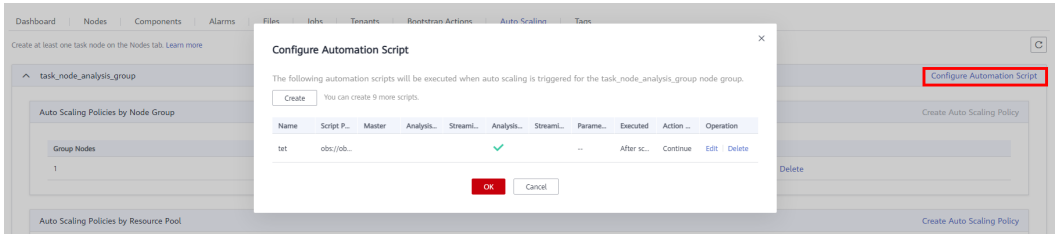
Step 1 Log in to the MRS management console.

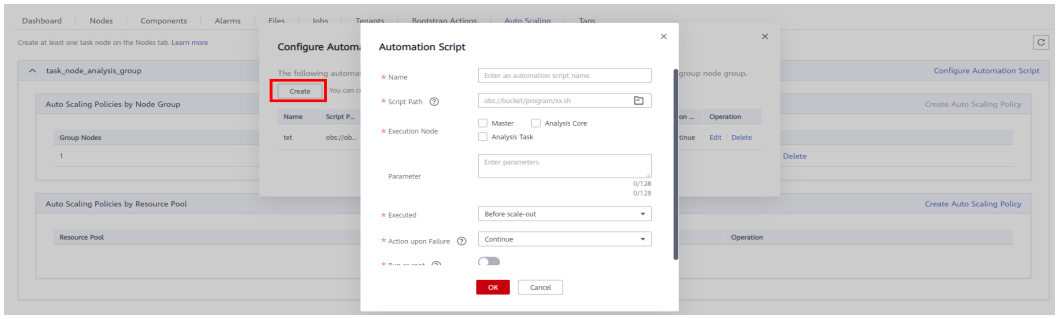
Step 2 Choose **Clusters** > **Active Clusters**. In the cluster list, select a running cluster to access its details page.

Step 3 Click the **Auto Scaling** tab.

Step 4 Click **Configure Automation Script**.

Step 5 Click **Add**.





Step 6 Configure **Name**, **Script Path**, **Execution Node**, **Parameter**, **Executed**, and **Action upon Failure**. For details about the parameters, see **Table 4-14**.

Step 7 Click **OK** to save the automation script configurations.

----End

4.7.12 Configuring Auto Scaling Metrics

Auto Scaling Policies by Node Group

When you add a rule, you can refer to **Table 4-11** to configure the corresponding metrics.

Table 4-11 Auto scaling metrics

Cluster Type	Metric	Value Type	Description
Streaming cluster	StormSlotAvailable	Integer	Number of available Storm slots Value range: 0 to 2147483646
	StormSlotAvailablePercentage	Percentage	Percentage of available Storm slots, that is, the proportion of the available slots to total slots Value range: 0 to 100
	StormSlotUsed	Integer	Number of used Storm slots Value range: 0 to 2147483646
	StormSlotUsedPercentage	Percentage	Percentage of the used Storm slots, that is, the proportion of the used slots to total slots Value range: 0 to 100
	StormSupervisorMemAverageUsage	Integer	Average memory usage of the Supervisor process of Storm Value range: 0 to 2147483646
	StormSupervisorMemAverageUsagePercentage	Percentage	Average percentage of the used memory of the Supervisor process of Storm to the total memory of the system Value range: 0 to 100
	StormSupervisorCPUAverageUsagePercentage	Percentage	Average percentage of the used CPUs of the Supervisor process of Storm to the total CPUs Value range: 0 to 6000
Analysis cluster	YARNAppPending	Integer	Number of pending tasks on YARN Value range: 0 to 2147483646

Cluster Type	Metric	Value Type	Description
	YARNAppPendingRatio	Ratio	Ratio of pending tasks on YARN, that is, the ratio of pending tasks to running tasks on YARN Value range: 0 to 2147483646
	YARNAppRunning	Integer	Number of running tasks on YARN Value range: 0 to 2147483646
	YARNContainerAllocated	Integer	Number of containers allocated to YARN Value range: 0 to 2147483646
	YARNContainerPending	Integer	Number of pending containers on YARN Value range: 0 to 2147483646
	YARNContainerPendingRatio	Ratio	Ratio of pending containers on Yarn, that is, the ratio of pending containers to running containers on YARN Value range: 0 to 2147483646
	YARNCPUAllocated	Integer	Number of virtual CPUs (vCPUs) allocated to YARN Value range: 0 to 2147483646
	YARNCPUAvailable	Integer	Number of available vCPUs on YARN Value range: 0 to 2147483646
	YARNCPUAvailablePercentage	Percentage	Percentage of available vCPUs on YARN that is, the proportion of available vCPUs to total vCPUs Value range: 0 to 100
	YARNCPUPending	Integer	Number of pending vCPUs on YARN Value range: 0 to 2147483646
	YARNMemoryAllocated	Integer	Memory allocated to YARN, in MB Value range: 0 to 2147483646
	YARNMemoryAvailable	Integer	Available memory on YARN in MB Value range: 0 to 2147483646

Cluster Type	Metric	Value Type	Description
	YARNMemoryAvailablePercentage	Percentage	Percentage of available memory on YARN that is, the proportion of available memory to total memory on YARN Value range: 0 to 100
	YARNMemoryPending	Integer	Pending memory on YARN Value range: 0 to 2147483646

NOTE

- When the value type is percentage or ratio in **Table 4-11**, the valid value can be accurate to percentile. The percentage metric value is a decimal value with a percent sign (%) removed. For example, 16.80 represents 16.80%.
- Hybrid clusters support all metrics of analysis and streaming clusters.

Auto Scaling Policies by Resource Pool

When adding a rule, you can refer to **Table 4-12** to configure the corresponding metrics.

NOTE

Auto scaling policies can be configured for a cluster by resource pool in MRS 3.1.5 or later.

Table 4-12 Rule configuration description

Cluster Type	Metric	Value Type	Description
Analysis/Custom cluster	ResourcePoolMemoryAvailable	Integer	Available memory on YARN in the resource pool, in MB Value range: 0 to 2147483646
	ResourcePoolMemoryAvailablePer-centage	Percentage	Percentage of available memory on YARN in the resource pool, that is, the proportion of available memory to total memory on YARN Value range: 0 to 100

Cluster Type	Metric	Value Type	Description
	ResourcePoolCPUAvailable	Integer	Number of available vCPUs on YARN in the resource pool Value range: 0 to 2147483646
	ResourcePoolCPUAvailablePercentage	Percentage	Percentage of available vCPUs on YARN in the resource pool. that is, the proportion of available vCPUs to total vCPUs Value range: 0 to 100

When you add a resource plan, you can configure parameters by referring to **Table 4-13**.

Table 4-13 Resource plan configuration items

Parameter	Description
Effective On	The effective date of a resource plan. **Daily** is selected by default. You can also select one or multiple days from Monday to Sunday.
Time Range	Start time and end time of a resource plan are accurate to minutes, with the value ranging from **00:00** to **23:59**. For example, if a resource plan starts at 8:00 and ends at 10:00, set this parameter to **8:00-10:00**. The end time must be at least 30 minutes later than the start time.
Node Range	The number of nodes in a resource plan ranges from **0** to **500**. In the time range specified in the resource plan, if the number of task nodes is less than the specified minimum number of nodes, it will be increased to the specified minimum value of the node range at a time. If the number of task nodes is greater than the maximum number of nodes specified in the resource plan, the auto scaling function reduces the number of task nodes to the maximum value of the node range at a time. The minimum number of nodes must be less than or equal to the maximum number of nodes.

NOTE

- When a resource plan is enabled, the **Default Range** value on the auto scaling page forcibly takes effect beyond the time range specified in the resource plan. For example, if **Default Range** is set to **1-2**, **Time Range** is between **08:00-10:00**, and **Node Range** is **4-5** in a resource plan, the number of Task nodes in other periods (0:00-8:00 and 10:00-23:59) of a day is forcibly limited to the default node range (1 to 2). If the number of nodes is greater than 2, auto scale-in is triggered; if the number of nodes is less than 1, auto scale-out is triggered.
- When a resource plan is not enabled, the **Default Range** takes effect in all time ranges. If the number of nodes is not within the default node range, the number of Task nodes is automatically increased or decreased to the default node range.
- Time ranges of resource plans cannot be overlapped. The overlapped time range indicates that two effective resource plans exist at a time point. For example, if resource plan 1 takes effect from **08:00** to **10:00** and resource plan 2 takes effect from **09:00** to **11:00**, the time range between **09:00** to **10:00** is overlapped.
- The time range of a resource plan must be on the same day. For example, if you want to configure a resource plan from **23:00** to **01:00** in the next day, configure two resource plans whose time ranges are **23:00-00:00** and **00:00-01:00**, respectively.

Automation Script

When you add an automation script, you can configure related parameters by referring to **Table 4-14**.

Table 4-14 Automation script configuration description

Parameter	Description
Name	Name of an automation script The value can contain only numbers, letters, spaces, hyphens (-), and underscores (_) and must not start with a space. The value can contain 1 to 64 characters. **NOTE** A name must be unique in the same cluster. You can configure the same name for different clusters.
Script Path	Script path. The value can be an OBS file system path or a local VM path. • An OBS file system path must start with **obs://** and end with **.sh**, for example, **obs://mrs-samples/*xxx*.sh**. • A local VM path must start with a slash (/) and end with **.sh**. For example, the path of the example script for installing the Zepelin is **/opt/bootstrap/zepelin/zepelin_install.sh**.

Parameter	Description
Execution Node	Select a type of the node where an automation script is executed. **NOTE** • If you select **Master** nodes, you can choose whether to run the script only on the active Master nodes by enabling or disabling the **Active Master** switch. • If you enable it, the script runs only on the active Master nodes. If you disable it, the script runs on all master nodes. This function is disabled by default.
Parameter	Automation script parameter. The following predefined variables can be imported to obtain auto scaling information: • **${mrs_scale_node_num}**: Number of auto scaling nodes. The value is always positive. • **${mrs_scale_type}**: Scale-out/in type. The value can be **scale_out** or **scale_in**. • **${mrs_scale_node_hostnames}**: Host names of the auto scaling nodes. Use commas (,) to separate multiple host names. • **${mrs_scale_node_ips}**: IP address of the auto scaling nodes. Use commas (,) to separate multiple IP addresses. • **${mrs_scale_rule_name}**: Name of the triggered auto scaling rule. For a resource plan, this parameter is set to **resource_plan**.
Executed	Time for executing an automation script. The following four options are supported: **Before scale-out**, **After scale-out**, **Before scale-in**, and **After scale-in**. **NOTE** Assume that the execution nodes include Task nodes. • The automation script executed before scale-out cannot run on the Task nodes to be added. • The automation script executed after scale-out can run on the added Task nodes. • The automation script executed before scale-in can run on Task nodes to be deleted. • The automation script executed after scale-in cannot run on the deleted Task nodes.
Action upon Failure	Whether to continue to execute subsequent scripts and scale-out/in after the script fails to be executed. **NOTE** • You are advised to set this parameter to **Continue** in the commissioning phase so that the cluster can continue the scale-out/in operation no matter whether the script is executed. • If the script fails to be executed, view the log in **/var/log/Bootstrap** on the cluster VM. • The scale-in operation cannot be rolled back. Therefore, the **Action upon Failure** can only be set to **Continue** after scale-in.

NOTE

The automation script is triggered only during auto scaling. It is not triggered when the cluster node is manually scaled out or in.

4.8 Managing Data Connections

4.8.1 Configuring Data Connections

MRS data connections are used to manage external source connections used by components in a cluster. For example, if Hive metadata uses an external relational database, a data connection can be used to associate the external relational database with the Hive component.

- **Local**: Metadata is stored in the local GaussDB of a cluster. When the cluster is deleted, the metadata is also deleted. To retain the metadata, manually back up the metadata in the database in advance.
- **External data connection**: After the cluster is created, you can select **RDS PostgreSQL database** or **RDS MySQL database** that is associated with the same VPC and subnet as the current cluster. Metadata is stored in the associated database and is not deleted when the current cluster is deleted. Multiple MRS clusters can share the same metadata.

NOTE

When Hive metadata is switched between different clusters, MRS synchronizes only the permissions in the metadata database of the Hive component. The permission model on MRS is maintained on MRS Manager. Therefore, when Hive metadata is switched between clusters, the permissions of users or user groups cannot be automatically synchronized to MRS Manager of another cluster.

Creating a Data Connection

Step 1 Log in to the MRS management console, and choose **Data Connections** in the left navigation pane.

Step 2 Click **Create Data Connection**.

For details about how to configure an RDS data connection, see **Creating an RDS Data Connection**.

NOTE

- **RDS MySQL database**. Clusters that support Hive or Ranger can connect to this type of database.
- Currently, MRS supports **PostgreSQL 14** on RDS.
- Currently, MRS supports only **MySQL 5.7.x/MySQL 8.0***x* on RDS.

Step 3 Click **OK**.

----End

Viewing Data Connection Details

Step 1 Log in to the MRS management console, and choose **Data Connections** in the left navigation pane.

Step 2 In the data connection list, click the desired data connection. On the page that is displayed, view its details.

----End

Deleting a Data Connection

Step 1 Log in to the MRS management console, and choose **Data Connections** in the left navigation pane.

Step 2 In the **Operation** column of the data connection list, click **Delete** in the row where the data connection to be deleted is located.

If the selected data connection has been associated with a cluster, the deletion does not affect the cluster.

----End

Configuring a Data Connection During Cluster Creation

Step 1 Click the **Custom Config** tab.

Step 2 When you create a cluster, **Data Connection Type** can only be set to **Local database**. For details about how to configure other parameters, see **Creating a Custom Cluster**.

----End

4.8.2 Configuring an RDS Data Connection

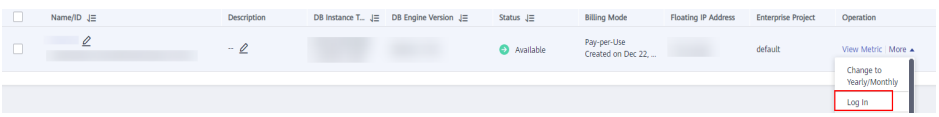
4.8.2.1 Configuring an RDS Data Connection

Preparations

Step 1 Log in to the RDS management console.

Step 2 Buy an RDS DB instance.

Step 3 In the left navigation pane of the RDS management console, choose **Instances**. Locate the row containing the RDS DB instance used by MRS data connections, click **More** in the **Operation** column, and select **Log In** to log in to the DB instance as user **root**.



Step 4 On the home page of the instance, click **Create Database** to create a database.

NOTE

If no new database is created, the MRS data connections will fail to configure.

Step 5 On the top of the page, choose **Account Management** > **User Management**.

NOTE

If the selected data connection is **RDS MySQL database**, ensure that the database user is user **root**. If the user is not **root**, perform **Step 5** to **Step 7**.

Step 6 Click **Create User** to create a non-root user.

Step 7 On the top of the page, choose **SQL Operations** > **SQL Query**, switch to the target database by database name, and run the following SQL statements to grant permissions to the database user. In the following statements, *${db_name}* and *${db_user}* indicate the name of the database to be connected to MRS and the name of the new user, respectively.

```
grant SELECT, INSERT on mysql.* to '${db_user}'@'%' with grant option;
grant all privileges on ${db_name}.* to '${db_user}'@'%' with grant option;
grant reload on *.* to '${db_user}'@'%' with grant option;
flush privileges;
```

Step 8 Create a data connection by referring to **Creating an RDS Data Connection**.

----End

Creating an RDS Data Connection

Create an RDS data connection for an existing MRS cluster.

Step 1 Log in to the MRS management console, and choose **Data Connections** in the left navigation pane.

Step 2 Click **Create Data Connection**.

Step 3 Configure parameters according to **Table 4-15**.

Table 4-15 Parameters for creating a data connection

Parameter	Description
Type	The type of an external source connection. Value options are as follows: • **RDS MySQL database**. Clusters that support Hive or Ranger can connect to this type of database.
Name	The name of a data connection.

Parameter	Description
Database Instance	The RDS database instance. This instance must be created in RDS before being referenced here, and the database must have been created. For details, see **Preparations**. Click **View DB Instance** to view the created DB instances. **NOTE** • To ensure network communications between the cluster and the PostgreSQL database, create the instance in the same VPC and subnet as the cluster. • The inbound rule of the security group of the RDS DB instance must allow access of the instance to port 3306. To configure that, click the instance name on the RDS console to go to the instance management page. In the **Connection Information** area, click the name next to **Security Group**. On the page that is displayed, click the **Inbound Rules** tab, and click **Add Rule**. In the displayed **Add Inbound Rule** dialog box, in the **Protocol & Port** area, select **TCP** and enter port number **3306**. In the **Source** area, select **IP address** and enter the IP addresses of all nodes where the MetaStore instances of Hive are located. • Currently, MRS supports **PostgreSQL 14** on RDS. • Currently, MRS supports only **MySQL 5.7.x/MySQL 8.0***x* on RDS.
Database	The name of the database to be connected to.
Username	The username for logging in to the database to be connected.
Password	The password for logging in to the database to be connected.

NOTE

When **Type** is set to **RDS MySQL database** or **GaussDB(for MySQL)**, **Username** must be **root**. If the user is not **root**, perform operations by referring to **Preparations**.

Step 4 Click **OK**.

----End

4.8.2.2 Configuring a Ranger Data Connection

Switch the Ranger metadata of the existing cluster to the metadata stored in the RDS database. This operation enables multiple MRS clusters to share the same metadata, and the metadata will not be deleted when the clusters are deleted. In this way, Ranger metadata migration is not required during cluster migration.

Prerequisites

You have created an RDS MySQL database instance by referring to **Creating an RDS Data Connection**.

NOTE

When **Type** is set to **RDS MySQL database**, **Username** must not be **root**. In this case, create a user and grant permissions to the user by referring to **Preparations**.

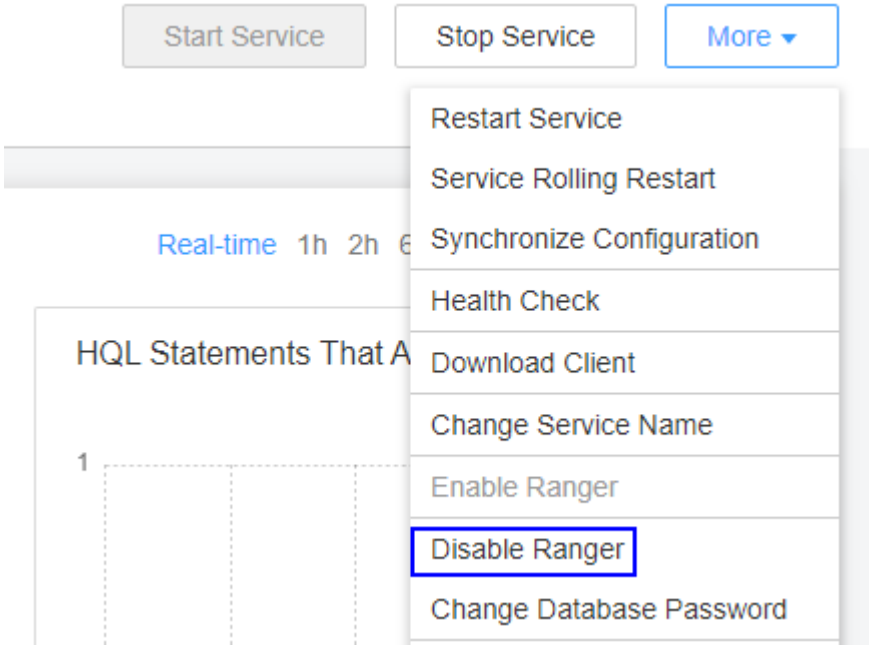
Preparing for MySQL Database Ranger Metadata Configuration

Step 1 Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager**. Choose **Clusters** > **Services** > *Service name*.

Currently, the following components in support Ranger authentication: HDFS, HBase, Hive, Spark, Impala, Storm, Elasticsearch, Hetu, and Kafka.

Step 2 In the upper right corner of the **Dashboard** page, click **More** and select **Disable Ranger**. If **Disable Ranger** is dimmed, Ranger authentication is disabled, as shown in **Figure 4-2**.

Figure 4-2 Disabling Ranger authentication



Step 3 (Optional) To use an existing authentication policy, perform this step to export the authentication policy on the Ranger web page. After the Ranger metadata is switched, you can import the existing authentication policy again. The following uses Hive as an example. After the export, a policy file in JSON format is generated in a local directory.

1. Log in to FusionInsight Manager.
2. Choose **Cluster** > **Services** > **Ranger** to go to the Ranger service overview page.
3. Click **RangerAdmin** in the **Basic Information** area to go to the Ranger web UI.

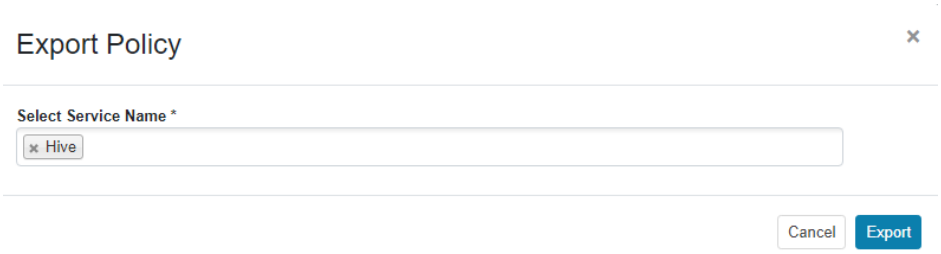
The **admin** user in Ranger belongs to the **User** type. To view all management pages, click the username in the upper right corner and select **Log Out** to log out of the system.

4. Log in to the system as user **rangeradmin** or another user who has the Ranger administrator permissions. For details about the users and their default passwords, contact the system administrator.
5. Click the export button  in the row where the Hive component is located to export the authentication policy.

Figure 4-3 Exporting authentication policies

6. Click **Export**. After the export is complete, a policy file in JSON format is generated in a local directory.

Figure 4-4 Exporting Hive authentication policies



----End

Configuring a Data Connection for an MRS Cluster

Step 1 Log in to the MRS console.

Step 2 Click the name of the cluster to view its details.

Step 3 Click **Manage** on the right of **Data Connection** to go to the data connection configuration page.

Step 4 Click **Configure Data Connection** and set related parameters.

- **Component Name**: Ranger
- **Module Type**: Ranger metadata
- **Connection Type**: RDS MySQL database
- **Connection Instance**: Select a created RDS MySQL DB instance. For details about how to create a data connection, see **Creating an RDS Data Connection**.

Step 5 Select **I understand the consequences of performing the scale-in operation** and click **Test**.

Step 6 After the test is successful, click **OK** to complete the data connection configuration.

Step 7 Log in to FusionInsight Manager.

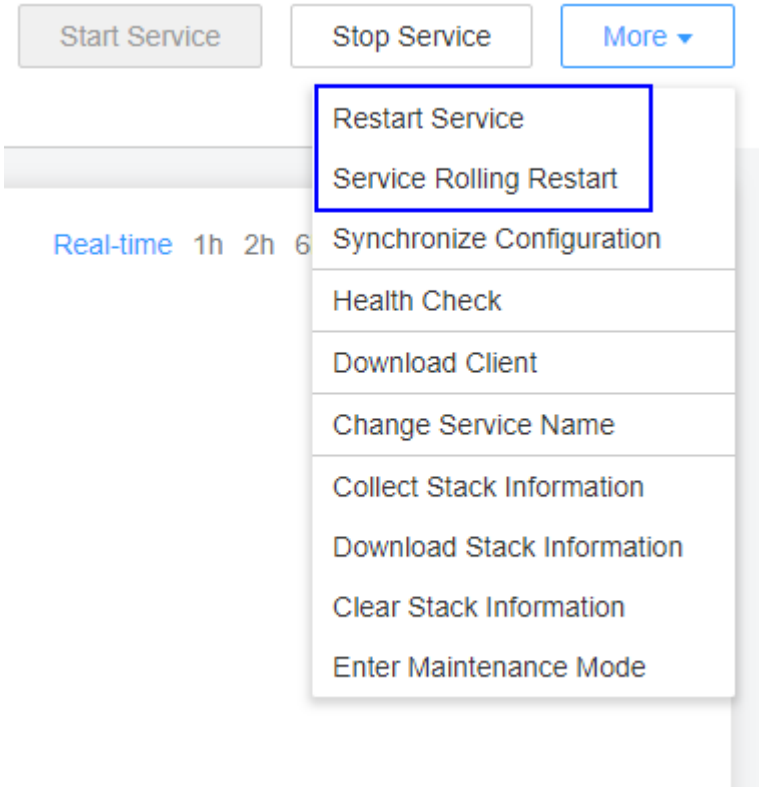
Step 8 Choose **Cluster** > **Services** > **Ranger** to go to the Ranger service overview page.

Step 9 Choose **More** > **Restart Service** or **More** > **Service Rolling Restart**.

If you choose **Restart Service**, services will be interrupted during the restart. If you select **Service Rolling Restart**, rolling restart can minimize the impact or do not affect service running.

Restarting Ranger will affect the permissions of all components controlled by Ranger and may affect service running. Restart Ranger when the cluster is idle or during off-peak hours. Before the Ranger component is restarted, the policies in the Ranger component still take effect.

Figure 4-5 Restarting a service

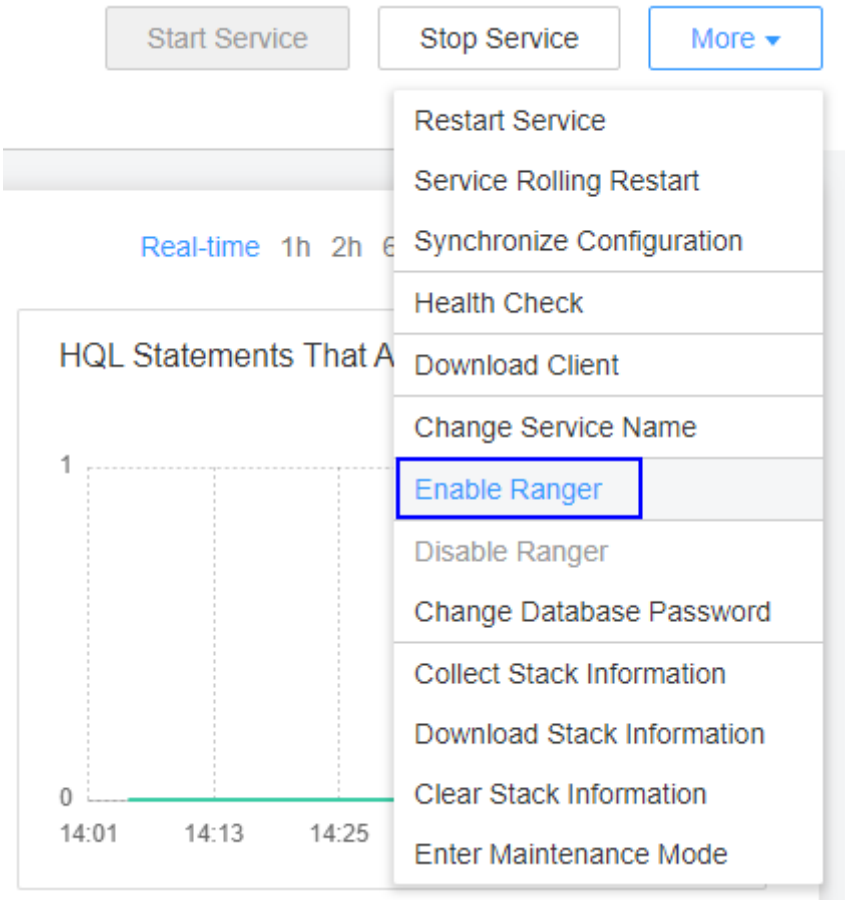


Step 10 Enable Ranger authentication for the component to be authenticated. The Hive component is used as an example.

Currently, the following components in an MRS cluster support Ranger authentication: HDFS, HBase, Hive, Spark, Impala, Storm, and Kafka.

1. Log in to FusionInsight Manager and choose **Cluster** > **Services** > *Service Name*.
2. In the upper right corner of the **Dashboard** page, click **More** and select **Enable Ranger**.

Figure 4-6 Enabling Ranger authentication

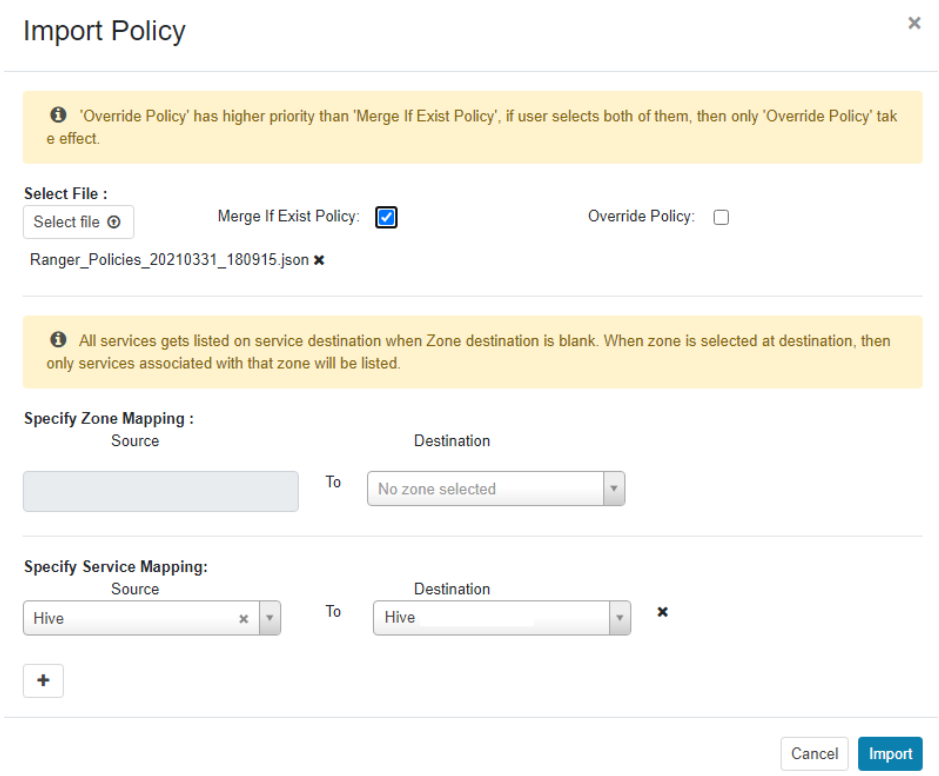


Step 11 Log in to the Ranger web UI and click the import button in the row of the Hive component.

Step 12 Import parameters.

- Click **Select file** and select the authentication policy file downloaded in **Step 3.6**.
- Select **Merge If Exist Policy**.

Figure 4-7 Importing authentication policies



Step 13 Restart the component for which Ranger authentication is enabled.

1. Log in to FusionInsight Manager.
2. Choose **Cluster** > **Services** > **Hive** to go to the Hive service overview page.
3. Choose **More** > **Restart Service** or **More** > **Service Rolling Restart**.

   If you choose **Restart Service**, services will be interrupted during the restart. If you select **Service Rolling Restart**, rolling restart can minimize the impact or do not affect service running.

----End

4.8.2.3 Configuring a Hive Data Connection

This section describes how to switch the Hive metadata of an active cluster to the metadata stored in a local database or RDS database after you create a cluster. This operation enables multiple MRS clusters to share the same metadata, and the metadata will not be deleted when the clusters are deleted. In this way, Hive metadata migration is not required during cluster migration.

NOTE

- When Hive metadata is switched between different clusters, MRS synchronizes only the permissions in the metadata database of the Hive component. The permission model on MRS is maintained on MRS Manager. Therefore, when Hive metadata is switched between clusters, the permissions of users or user groups cannot be automatically synchronized to MRS Manager of another cluster.
- When **Type** is set to **RDS MySQL database**, **Username** must not be **root**. In this case, create a user and grant permissions to the user by referring to **Preparations**.

Configuring a Hive Data Connection

Step 1 Log in to the MRS console. In the navigation pane on the left, choose **Clusters** > **Active Clusters**.

Step 2 Click the name of a cluster to go to the cluster details page.

Step 3 On the **Dashboard** tab page, click **Manage** next to **Data Connection**.

Step 4 On the **Data Connection** dialog box, the data connections associated with the cluster are displayed. You can click **Edit** or **Delete** to edit or delete the data connections.

Step 5 If there is no associated data connection on the **Data Connection** dialog box, click **Configure Data Connection** to add a connection.

NOTE

Only one data connection can be configured for a module type. For example, after a data connection is configured for Hive metadata, no other data connection can be configured for it. If no module type is available, the **Configure Data Connection** button is unavailable.

Table 4-16 Configuring a Hive data connection

Parameter	Description
Component	Hive
Module Type	Hive metadata
Data Connection Type	• RDS MySQL database • Local database
Instance	This parameter is valid only when **Data Connection Type** is set to **RDS PostgreSQL database** or **RDS MySQL database**. Select the name of the connection between the MRS cluster and the RDS database. This instance must be created before being referenced here. You can click **Create Data Connection** to create a data connection. For details, see **Creating an RDS Data Connection**.

Step 6 Click **Test** to test connectivity of the data connection.

Step 7 After the data connection is successful, click **OK**.

NOTE

- After Hive metadata is configured, restart Hive. Hive will create necessary database tables in the specified database. (If tables already exist, they will not be created.)
- Before restarting the Hive service, ensure that the driver package has been installed on all nodes where Metastore instances are located.
  - Postgres: Use the open source Postgres driver package to replace the existing one of the cluster. Upload the PostgreSQL driver package **postgresql-42.2.5.jar** to the *${BIGDATA_HOME}*/**third_lib/Hive** directory on all MetaStore nodes.
  - MySQL: Go to the MySQL official website (https://www.mysql.com/). Choose **DOWNLOADS** and click **MySQL Community (GPL) Downloads**. On the displayed page, click **Connector/J** to download the driver package of the corresponding version and upload the driver package to the **/opt/Bigdata/FusionInsight_HD_*/install/FusionInsight-Hive-*/hive-*/lib/** directory on all RDSMetastore nodes.

----End

4.9 Installing Third-Party Software Using Bootstrap Actions

Prerequisites

The bootstrap action script has been prepared by referring to **Preparing the Bootstrap Action Script**.

Adding a Bootstrap Action When Creating a Cluster

Step 1 Click the **Custom Config** tab.

Step 2 Configure the cluster software and hardware by referring to **Creating a Custom Cluster**.

Step 3 In the **Set Advanced Options** area, select **Configure** and click **Add** in the **Bootstrap Action** area.

Table 4-17 Parameters

Parameter	Description
Name	Name of a bootstrap action script The value can contain only digits, letters, spaces, hyphens (-), and underscores (_) and must not start with a space. The value can contain 1 to 64 characters. **NOTE** A name must be unique in the same cluster. You can set the same name for different clusters.

Parameter	Description
Script Path	Script path. The value can be an OBS file system path or a local VM path. • An OBS file system path must start with **obs://** and end with **.sh**, for example, **obs://mrs-samples/***xxx***.sh**. • A local VM path must start with a slash (/) and end with **.sh**. **NOTE** A path must be unique in the same cluster, but can be the same for different clusters.
Parameter	Bootstrap action script parameters
Execution Node	Select a type of the node where the bootstrap action script is executed.
Executed	Select the time when the bootstrap action script is executed. • Before initial component start • After initial component start **NOTE** You can only manually run the third-party component installation script on the node to install a running cluster component.
Action upon Failure	Whether to continue to execute subsequent scripts and create a cluster after the script fails to be executed. **NOTE** You are advised to set this parameter to **Continue** in the debugging phase so that the cluster can continue to be installed and started no matter whether the bootstrap action is successful.
Run as root	Whether to escalate the permission to user **root** If the bootstrap action requires root user operations, enable this function, or the bootstrap action may fail to execute.

Step 4 Click **OK**.

After the bootstrap action is added, you can edit, clone, or delete it in the **Operation** column.

----End

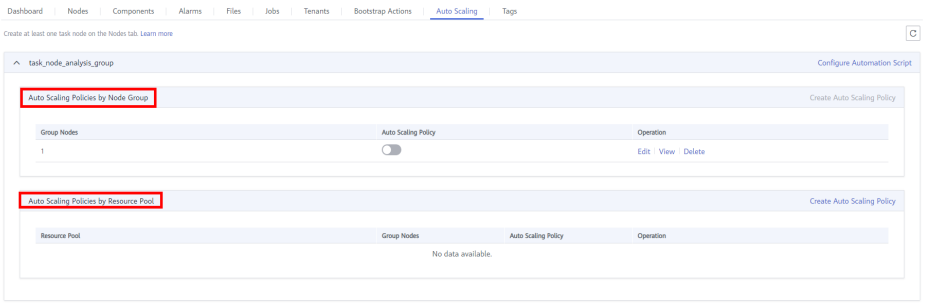
Adding an Automation Script on the Auto Scaling Page

Step 1 Log in to the MRS management console.

Step 2 Choose **Clusters** > **Active Clusters**. In the cluster list, select a running cluster to access its details page.

Step 3 On the page that is displayed, click the **Auto Scaling** tab.

You can configure policies by resource pool or node group as needed. For details, see **Creating an Auto Scaling Policy for an Existing Cluster**



NOTE

- Auto scaling policies of different node groups are mutually exclusive. That is, you can enable auto scaling policies only for one node group.

Step 4 (Optional) Configure automation scripts.

1. Click **Configure Automation Script**.
2. Click **Add**.
3. Configure **Name**, **Script Path**, **Execution Node**, **Parameter**, **Executed**, and **Action upon Failure**. For details about the parameters, see **Table 4-14**.
4. Click **OK** to save the automation script configurations.

----End

4.10 Viewing Failed MRS Tasks

This section describes how to view and delete a failed MRS task.

Background

If a cluster fails to be created, deleted, scaled out, or scaled in, the **Manage Failed Tasks** page is displayed. Only the tasks that fail to be deleted are displayed on the **Cluster History** page. You can delete a failed task that is not required.

Procedure

Step 1 Log in to the MRS console.

Step 2 In the left navigation pane, choose **Clusters** > **Active Clusters**.

Step 3 Click or the number on the right of **Failed Tasks**. The **Manage Failed Tasks** page is displayed.

Step 4 In the **Operation** column of the cluster that you want to start, click **Delete**.

In this step, only one job can be deleted.

Step 5 You can click **Delete All** in the upper left corner of the task list to delete all failed tasks.

----End

4.11 Viewing Information of a Historical Cluster

Choose **Clusters > Cluster History** and click the name of a target cluster. You can view the cluster configuration information, nodes, auto scaling information, component information, job information, bootstrap action, and tags.

The following table describes the parameters for the historical cluster information.

Table 4-18 Basic cluster information

Parameter	Description
Cluster Name	Name of a cluster. The cluster name is set when the cluster is created.
Cluster Status	Status of a cluster.
Cluster Version	Cluster version
Cluster Type	Type of the cluster to be created.
Obtaining a cluster ID	Unique identifier of a cluster, which is automatically assigned when a cluster is created
Created	Time when a cluster is created.
AZ	Availability zone (AZ) in the region of a cluster, which is set when a cluster is created.
Default Subnet	Subnet selected during cluster creation. A subnet provides dedicated network resources that are isolated from other networks, improving network security.
VPC	VPC selected during cluster creation. A VPC is a secure, isolated, and logical network environment.
OBS Permission Control	Click **Manage** and modify the mapping between MRS users and OBS permissions. For details, see **Configuring Fine-Grained Permissions for MRS Multi-User Access to OBS**.
Creating a data connection	Click **Manage** to view the data connection type associated with the cluster. For details, see **Configuring Data Connections**.

Parameter	Description
Agency	Click **Manage Agency** to bind or modify an agency for the cluster. An agency allows ECS or BMS to manage MRS resources. You can configure an agency of the ECS type to automatically obtain the AK/SK to access OBS. For details, see **Configuring a Storage-Compute Decoupled Cluster (Agency)**. The **MRS_ECS_DEFAULT_AGENCY** agency has the OBSOperateAccess permission of OBS and the CESFullAccess (for users who have enabled fine-grained policies), CES Administrator, and KMS Administrator permissions in the region where the cluster is located.
Key Pair	Name of a key pair. Set this parameter when creating a cluster. If the login mode is set to password during cluster creation, this parameter is not displayed.
Kerberos Authentication	Whether to enable Kerberos authentication when logging in to Manager. **NOTE** Kerberos authentication cannot be manually enabled or disabled after the cluster is created. Set this parameter with caution when creating a cluster. If you need to change the authentication status, you are advised to create a new cluster.
Security Group	Security group name of the cluster.
Data Disk Key Name	Name of the key used to encrypt data disks. To manage the used keys, log in to the key management console.
Data Disk Key ID	ID of the key used to encrypt data disks.
Component Version	Version of each component installed in the cluster.
Agency	Delegates ECSs or BMSs to manage some of your resources.

Go back to the historical clusters page. You can use the following buttons to perform operations. For details about the buttons, see the following table.

Table 4-19 Icon description

Icon	Description
	Click  to manually refresh the node information.
	Enter a cluster name in the search bar and click  to search for a cluster.

5 Managing Clusters

5.1 Logging In to a Cluster

5.1.1 MRS Cluster Node Overview

An MRS cluster consists of multiple ECSs. The system manages nodes in node groups based on specifications. Nodes in the same node group use same ECS specifications. Nodes in a cluster can be classified into Master nodes, Core nodes, and Task nodes based on the roles of components deployed on the nodes. For details about the node types, see **Table 5-1**.

Table 5-1 Cluster node types

Node Type	Functions
Master node	Management node of an MRS cluster. It manages and monitors the cluster. In the navigation tree of the MRS management console, choose **Clusters** > **Active Clusters**, select a running cluster, and click its name to switch to the cluster details page. On the **Nodes** tab page, view the **Name**. The node that contains **master1** in its name is the Master1 node. The node that contains **master2** in its name is the Master2 node. You can log in to a Master node either using VNC on the ECS management console or using SSH. After logging in to the Master node, you can access Core nodes without entering passwords. The system automatically deploys the Master nodes in active/standby mode and supports the high availability (HA) feature for MRS cluster management. If the active management node fails, the standby management node switches to the active state and takes over services. To determine whether the Master1 node is the active management node, see **Determining Active and Standby Management Nodes**.
Core node	Work node of an MRS cluster. It processes and analyzes data and stores process data. In the **Nodes** tab of the cluster details page, the nodes in the node group whose **Node Type** includes **Core** are core nodes.
Task node	Compute node. When the compute resources of a cluster are insufficient, you can configure elastic scaling policies to increase nodes automatically. In the **Nodes** tab of the cluster details page, the nodes in the node group whose **Node Type** is **Task** are task nodes. If only the **NodeManager (Yarn)** or **Supervisor (Storm)** role is deployed in a node group in addition to basic mandatory roles, this node group is a Task node group.

MRS cluster nodes support remote login. The following remote login methods are available:

- GUI login: Use the remote login function provided by the ECS management console to log in to the Linux interface of the Master node in the cluster.
- SSH login: Applies to Linux ECSs only. You can use a remote login tool (such as PuTTY) to log in to an ECS. The ECS must have a bound EIP.

For details about how to apply for and bind EIP for the Master node, see **Virtual Private Cloud** > **User Guide** > **Elastic IP** > **Assigning an EIP and Binding It to an ECS**.

You can log in to a Linux ECS using either a key pair or password.

NOTICE

If you need to use a key pair to access a cluster node, you need to log in to the node as user **root**. For details, see **Logging In to an ECS Using a Key Pair (SSH)**.

For details about how to access a cluster node using a password, see **Logging In to an ECS Using a Password (SSH)**.

5.1.2 Logging In to an ECS

This section describes how to remotely log in to an ECS in an MRS cluster using the remote login (VNC mode) function provided on the ECS management console or a key or password (SSH mode). Remote login (VNC mode) is mainly used for emergency O&M. In other scenarios, it is recommended that you log in to the ECS using SSH.

NOTE

To log in to a cluster node using SSH, you need to add an inbound rule to the security group of the cluster. Set **Source** to *IPv4 address of the client*/**32** or *IPv6 address of the client*/**128** and set the port number to **22**.

Logging In to an ECS Using VNC

Step 1 Log in to the MRS management console.

Step 2 Choose **Clusters** > **Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.

Step 3 On the **Nodes** tab page, click the name of a Master node in the Master node group to log in to the ECS management console.

Step 4 In the upper right corner, click **Remote Login**.

Step 5 Enter the username and password for logging in to the Master node as prompted.

1. If you select **Password** for **Login Mode**, you need to enter **root** in **Username** and the password you set during cluster creation in **Password**.
2. If you select **Key Pair** for **Login Mode** when creating a cluster, perform the following operations to log in to the cluster:
   a. After the cluster is created, assign an EIP and bind it to the Master node of the cluster. For details, see **Virtual Private Cloud** > **User Guide** > **Elastic IP Address** > **Assigning an EIP and Binding It to an ECS**.
   b. Remotely log in to the Master node in SSH mode as user **root** using the key file.
   c. Run the **passwd root** command to set a password for user **root**.

d. Go back to the login interface, and enter **root** and the password set in **Step 5.2.c** to log in to the node.

----End

Logging In to an ECS Using a Key Pair (SSH)

Logging In to the ECS from Local Windows

To log in to the Linux ECS from local Windows, perform the operations described in this section. The following procedure uses PuTTY as an example to log in to the ECS.

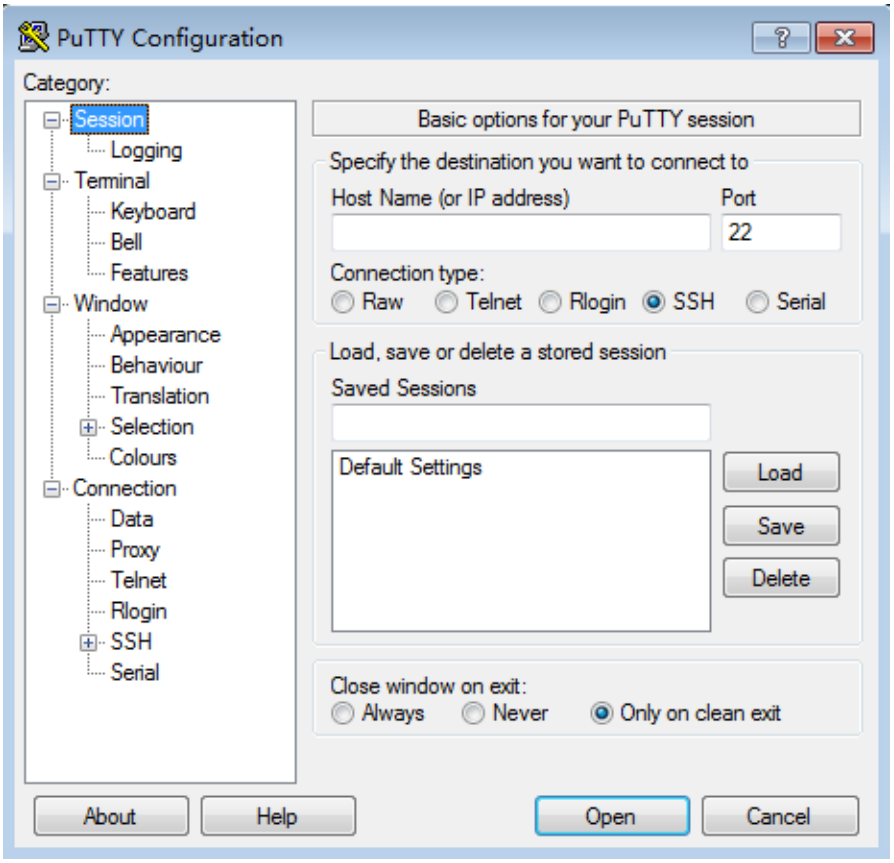
1. Log in to the MRS management console.
2. Choose **Clusters** > **Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.
3. On the **Nodes** tab page, click the name of a Master node in the Master node group to log in to the ECS management console.
4. Click the **EIPs** tab, click **Bind EIP** to bind an EIP to the ECS, and record the EIP. If an EIP has been bound to the ECS, skip this step.
5. Check whether the private key file has been converted to **.ppk** format.
   - If yes, go to **10**.
   - If no, go to **6**.
6. Run PuTTY.
7. In the **Actions** area, click **Load** and import the private key file you used during ECS creation.

   Ensure that the private key file is in the format of **All files (*.*)**.
8. Click **Save private key**.
9. Save the converted private key, for example, **kp-123.ppk**, to a local directory.
10. Run PuTTY.
11. Choose **Connection** > **Data**. Enter the image username in **Auto-login username**.

    NOTE

    The image username for cluster nodes is **root**.
12. Choose **Connection** > **SSH** > **Auth**. In the last configuration item **Private key file for authentication**, click **Browse** and select the private key converted in **9**.
13. Click **Session**.
    a. **Host Name (or IP address)**: Enter the EIP bound to the ECS.
    b. **Port**: Enter **22**.
    c. **Connection Type**: Select **SSH**.
    d. **Saved Sessions**: Task name, which can be clicked for remote connection when you use PuTTY next time

Figure 5-1 Clicking **Session**



14. Click **Open** to log in to the ECS.

    If you log in to the ECS for the first time, PuTTY displays a security warning dialog box, asking you whether to accept the ECS security certificate. Click **Yes** to save the certificate to your local registry.

Logging In to the ECS from Local Linux

To log in to the Linux ECS from local Linux, perform the operations described in this section. The following procedure uses private key file **kp-123.pem** as an example to log in to the ECS. The name of your private key file may differ.

1. On the Linux CLI, run the following command to change operation permissions:

   chmod 400 /*path*/kp-123.pem

   NOTE

   In the preceding command, *path* refers to the path where the key file is saved.

2. Run the following command to log in to the ECS:

   ssh -i /*path*/kp-123.pem*Default username*@*EIP*

   For example, if the default username is **root** and the EIP is **123.123.123.123**, run the following command:

   ssh -i /*path*/kp-123.pem root@123.123.123.123

NOTE

- *path* indicates the path where the key file is saved.
- *EIP* indicates the EIP bound to the ECS.
- The image username is **root** for cluster nodes.

Logging In to an ECS Using a Password (SSH)

Logging In to the ECS from Local Windows

To log in to the Linux ECS from local Windows, perform the operations described in this section. The following procedure uses PuTTY as an example to log in to the ECS.

Step 1 Log in to the MRS management console.

Step 2 Choose **Clusters > Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.

Step 3 On the **Nodes** tab page, click the name of a Master node in the Master node group to log in to the ECS management console.

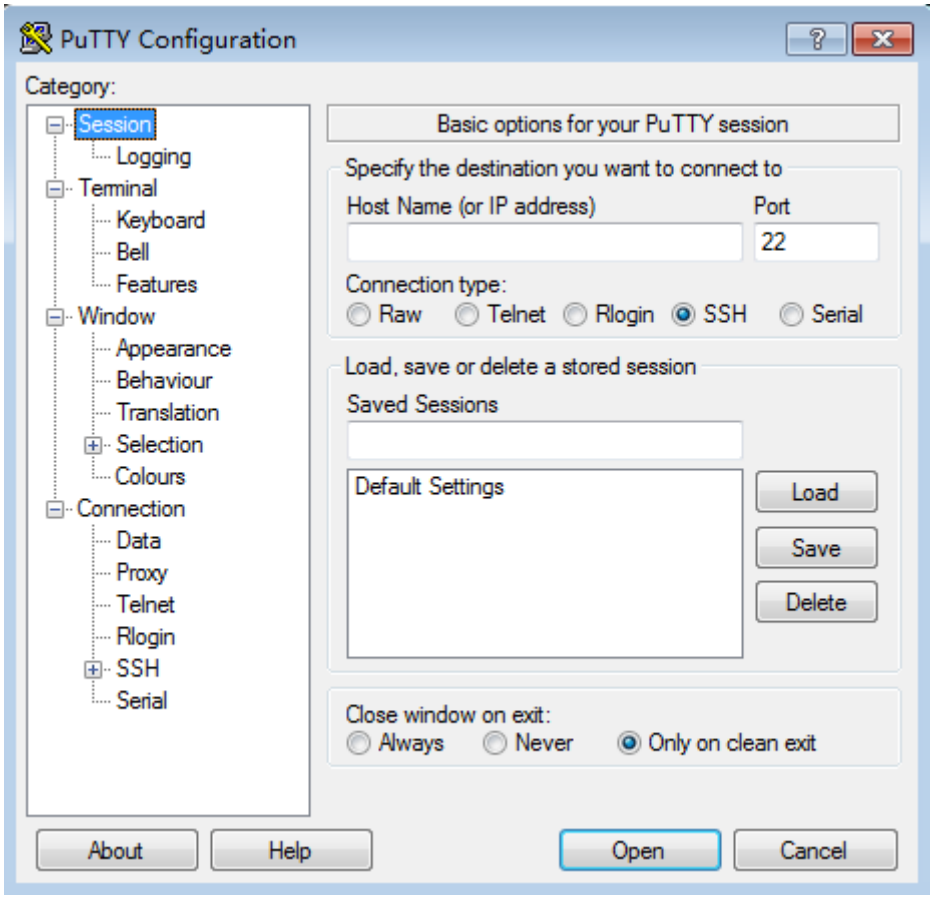
Step 4 Click the **EIPs** tab, click **Bind EIP** to bind an EIP to the ECS, and record the EIP. If an EIP has been bound to the ECS, skip this step.

Step 5 Run PuTTY.

Step 6 Click **Session**.

1. **Host Name (or IP address)**: Enter the EIP bound to the ECS.
2. **Port**: Enter **22**.
3. **Connection Type**: Select **SSH**.
4. **Saved Sessions**: Task name, which can be clicked for remote connection when you use PuTTY next time

Figure 5-2 Clicking **Session**



Step 7 Click **Window** and select **UTF-8** for **Remote character set:** in **Translation**.

Step 8 Click **Open** to log in to the ECS.

If you log in to the ECS for the first time, PuTTY displays a security warning dialog box, asking you whether to accept the ECS security certificate. Click **Yes** to save the certificate to your local registry.

Step 9 After the SSH connection to the ECS is set up, enter the username and password as prompted to log in to the ECS.

NOTE

The username is **root** and the password is the one you set during cluster creation.

----End

Logging In to the ECS from Local Linux

If the local host runs Linux, perform steps **Step 1** to **Step 4** to bind an EIP to the ECS, and run the following command on the CLI to log in to the ECS: **ssh *EIP bound by the ECS***

5.1.3 Determining Active and Standby Management Nodes

Scenario

Some O&M operation scripts and commands need to be run or can be run only on the active management node. You can log in to a Master node or the Manager to

determine the active and standby management nodes (active and standby OMS nodes).

In active/standby mode, a switchover can be implemented between Master1 and Master2. For this reason, Master1 may not be the active management node for Manager.

Runing the Script to Determine Active and Standby Nodes

Step 1 Find the Master nodes of an MRS cluster.

1. Log in to the MRS console, choose **Clusters** > **Active Clusters** and click the name of the target cluster to access its details page.
2. On the **Nodes** tab page, view Master node names. The node that contains **master1** in its name is the Master1 node. The node that contains **master2** in its name is the Master2 node.

Step 2 Determine the active and standby management nodes of the Manager.

1. Remotely log in to the Master1 node. For details, see **Logging In to an ECS**.

   Master nodes support Cloud-Init. The preset username for Cloud-Init is **root** and the password is the one you set during cluster creation.
2. Run the following commands to switch the user:

   sudo su - root

   su - omm
3. Run the following command to identify the active and standby management nodes:

   Run the **sh ${BIGDATA_HOME}/om-server/om/sbin/status-oms.sh** command.

   In the command output, the node whose **HAActive** is **active** is the active management node (mgtomsdat-sh-3-01-1 in the following example), and the node whose **HAActive** is **standby** is the standby management node (mgtomsdat-sh-3-01-2 in the following example).

```
Ha mode
double
NodeName            HostName                HAVersion       StartTime           HAActive
HAAllResOK          HARunPhase
192-168-0-30        mgtomsdat-sh-3-01-1     V100R001C01     20xx-11-18 23:43:02
active              normal                  Actived
192-168-0-24        mgtomsdat-sh-3-01-2     V100R001C01     20xx-11-21 07:14:02
standby             normal                  Deactived
```

   NOTE

   If the Master1 node to which you have logged in is the standby management node and you need to log in to the active management node, run the following command:

   ssh *IP address of Master2 node*

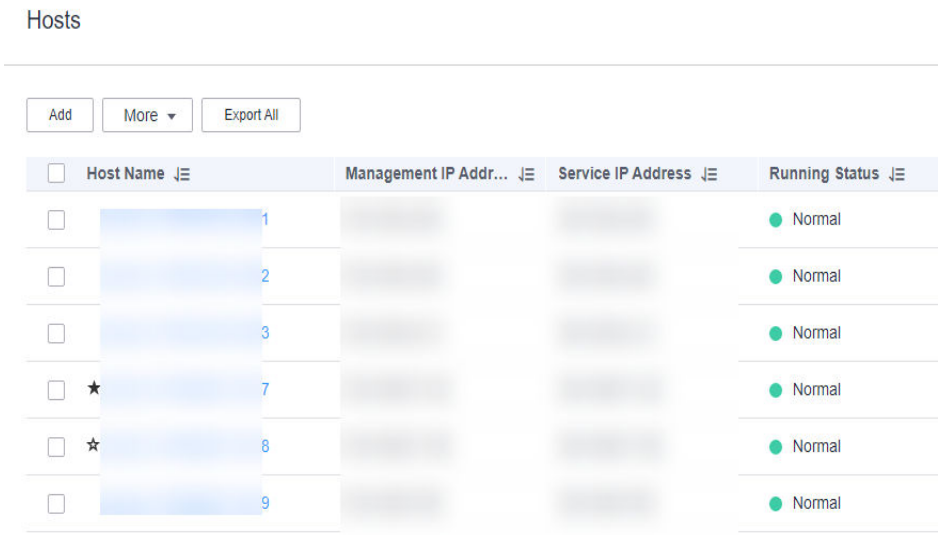
----End

Logging in to Manager to Determine Active and Standby Nodes

Step 1 Log in to Manager. For details, see **Accessing FusionInsight Manager**.

Step 2 Click **Hosts**. The **Hosts** page is displayed.

Step 3 View and record the IP addresses of the active and standby management nodes.



- If a host name starts with ★, it is the active management node (active OMS node). View and record the value of **Management IP Address** in the row containing the active node.
- If a host name starts with ☆, the host is a standby management node (standby OMS node). View and record the value of **Management IP Address** in the row containing the standby node.

----End

5.2 Cluster Overview

5.2.1 Cluster List

You can quickly view the status of all clusters and jobs by viewing the dashboard information, and obtain relevant MRS documents from **Help** in the left navigation pane on the MRS console.

MRS is used to manage and analyze massive data. It is easy to use. You can create a cluster and add MapReduce, Spark, and Hive jobs to the cluster to analyze and process user data. After being processed, you can transmit the data in SSL encryption mode to OBS to ensure data integrity and confidentiality.

Cluster Status

Log in to the MRS management console. You can view the status of existing clusters in the active cluster list. You search for status clusters in a specified status from the **Status** drop-down list. **Table 5-2** lists all the cluster statuses.

Table 5-2 Cluster status

Status	Description
Starting	If a cluster is being created, the cluster is in the **Starting** state.
Running	If a cluster is successfully created and is running properly, its status is **Running**.
Scaling out	If the Master, Core, or Task node in a cluster is being added, the cluster is in the **Scaling out** state. **NOTE** If the cluster scale-out fails, you can add node to the cluster again.
Scaling in	If a cluster node is being deleted, the cluster node is in the **Scaling in** state. This state shows when you scale in or elastically scale in a cluster node, change the OS, or reinstall the OS.
Abnormal	If some components in a cluster are abnormal, the cluster is **Abnormal**.
Deleting	If a pay-per-use cluster node is being deleted, the cluster status changes to **Deleting**. This state is displayed after you click **Delete** and confirm the deletion.
Restoring node...	If a faulty node in the cluster is being recovered, its status is **Restoring node...**.

Job Status

Table 5-3 describes the status of jobs that you execute after logging in to the MRS management console.

Table 5-3 Job status

Status	Description
Accepted	Initial status of a job after it is successfully submitted.
Running	A job is being executed.
Completed	A job has been executed and completed successfully.
Terminated	A job is stopped during execution.
Abnormal	An error occurs during job execution or job execution fails.

5.2.2 Checking the Cluster Status

The cluster list contains all clusters in MRS. You can view clusters in various states. If a large number of clusters are involved, navigate through multiple pages to view all of the clusters.

MRS, as a platform managing and analyzing massive data, provides a PB-level data processing capability. MRS allows you to create multiple clusters. The cluster quantity is subject to that of ECSs.

Clusters are listed in chronological order by default in the cluster list, with the most recent cluster displayed at the top. **Table 5-4** describes the cluster list parameters.

- **Active Clusters**: contain all clusters except the clusters in the **Failed** and **Deleted** states.
- **Cluster History**: contains the clusters in the **Deleted** states. Only clusters deleted within the last six months are displayed. If you want to view clusters deleted six months ago, contact technical support.
- **Failed Tasks**: only contain the tasks in the **Failed** state. You can click on the **Active Cluster** page to view failed tasks.

Table 5-4 Parameters in the active cluster list

Parameter	Description
Name/ID	Cluster name, which is set when a cluster is created. Unique identifier of a cluster, which is automatically assigned when a cluster is created. • : Change the cluster name. • : Copy the cluster ID.
Cluster Version	Cluster version.
Cluster Type	The type of a cluster you want to create.
Nodes	Number of nodes that can be deployed in a cluster. This parameter is set when a cluster is created.

Parameter	Description
Status	Status and operation progress description of a cluster. The cluster creation progress includes: • Verifying cluster parameters • Applying for cluster resources • Creating VMs • Initializing VMs • Installing MRS Manager • Deploying the cluster • Cluster installation failed The cluster scale-out progress includes: • Preparing for scale-out • Creating VMs • Initializing VMs • Adding nodes to the cluster • Scale-out failed The cluster scale-in progress includes: • Preparing for scale-in • Decommissioning instance • Deleting VMs • Deleting nodes from the cluster • Scale-in failed The system will display causes of cluster installation, scale-out, and scale-in failures. For details, see **Table 4-6**.
Created	The time when a cluster node is successfully created. This parameter is displayed only on the **Cluster History** page.
Deleted	Time when a cluster node stops and the cluster node begins to be deleted. This parameter is valid only for historical clusters displayed on the **Cluster History** page.
AZ	Availability zone (AZ) in the region of a cluster, which is set when a cluster is created.
Enterprise Project	Enterprise project to which a cluster belongs.

Parameter	Description
Operation	• **Delete**: If the cluster is no longer needed after the job execution is complete, you can click **Delete**. To confirm deletion, enter **DELETE** in the displayed dialog box and click **OK**. The cluster status changes from **Running** to **Deleting**. After the cluster is deleted, the cluster status changes to **Deleted** and is displayed in the historical cluster list. A cluster failed to be deployed will be automatically deleted. This parameter is displayed in **Active Clusters** only. **NOTE** Typically after data is analyzed and stored, or when the cluster encounters an exception and cannot work, you can delete a cluster. If a cluster is deleted before data processing and analysis are completed, data loss may occur. Therefore, exercise caution when deleting a cluster.

Table 5-5 Button description

Button	Description
	Select an enterprise project from the drop-down list to filter the corresponding cluster.
	Select a status to filter clusters from the drop-down list: • All statuses • Starting • Running • Scaling out • Scaling in • Abnormal • Deleting • Restoring node...
	Choose **Clusters > Active Clusters** and click  to go to the page for managing failed tasks.  *Num*: displays the failed tasks in the **failed** state.
	Enter a cluster name in the search bar and click  to search for a cluster.
Search by Tag	Click **Search by Tag**, enter the tag of the cluster to be queried, and click **Search** to search for the clusters. You can select a tag key or tag value from their drop-down lists. When the tag key or tag value is exactly matched, the system can automatically locate the target cluster. If you enter multiple tags, their intersections are used to search for the cluster.

Button	Description
	Click  to manually refresh the cluster list.

5.2.3 Viewing Basic Cluster Information

You can monitor and manage the clusters you have created. Choose **Clusters > Active Clusters**. Select a cluster and click its name to go to the cluster details page. On the displayed page, view the basic configuration and node information of the cluster.

On the cluster details page, click **Dashboard**. **Table 5-6**, **Table 5-7**, **Table 5-8**, and **Table 5-9** describe the parameters on the **Dashboard** tab page.

Table 5-6 Basic information

Parameter	Description
Cluster Name	The name of a cluster. Configure this parameter when creating a cluster. Click  to change the cluster name.
Cluster Status	The cluster status. For details, see **Table 5-2**.
Cluster Version	MRS version information.
Cluster Type	There are three types of clusters: • **Analysis Cluster**: is used for offline data analysis and provides Hadoop components. • **Streaming Cluster**: is used for streaming tasks and provides stream processing components. • **Hybrid Cluster**: is used for both offline data analysis and streaming processing and provides Hadoop components and streaming processing components. • **Custom**: An MRS cluster with all custom components.
Cluster ID	Unique identifier of a cluster, which is automatically assigned when a cluster is created.
Created	Time when a cluster is created.
AZ	Availability zone (AZ) in the region of a cluster, which is set when a cluster is created.
Kerberos Authentication	Whether to enable Kerberos authentication when logging in to Manager.
Enterprise Project	The enterprise project to which a cluster belongs. Only on the **Active Clusters** page, you can click the name of an enterprise project to go to its **Enterprise Project Management** page.

Table 5-7 Network information

Parameter	Description
Default Subnet	The subnet selected during cluster creation. If the subnet IP addresses are insufficient, click **Change Subnet** to switch to another subnet in the same VPC of the current cluster to obtain more available subnet IP addresses. Changing a subnet does not affect the IP addresses and subnets of existing nodes. A subnet provides dedicated network resources that are isolated from other networks, improving network security.
VPC	VPC selected during cluster creation. A VPC is a secure, isolated, and logical network environment.
EIP	After binding an EIP to an MRS cluster, you can use the EIP to access the Manager web UI of the cluster. If you do not need the EIP, click **Unbind** to unbind the EIP from the cluster. The Manager will not be accessible through the unbound EIP. **NOTE** If you unbind the EIP from a cluster, other users may fail to access the Manager of that cluster.
Security Group	The security group name of the cluster.

Table 5-8 O&M management

Parameter	Description
MRS Manager	Portal for the Manager page. see **Accessing FusionInsight Manager**.
IAM User Sync	IAM user information (including federated users) can be synchronized to an MRS cluster for cluster management. For details, see **Synchronizing IAM Users to MRS**. **NOTE** The **Components**, **Tenants**, and **Backups & Restorations** tab pages on the cluster details page can be used only after users are synchronized. For a federated user, only information about the user that logged in the system can be synchronized.
Data Connection	Click **Manage** to view the data connection type associated with the cluster. For details, see **Configuring Data Connections**.

Parameter	Description
Agency	Click **Manage Agency** to bind or modify an agency for the cluster. An agency allows ECS or BMS to manage MRS resources. You can configure an agency of the ECS type to automatically obtain the AK/SK to access OBS. For details, see **Configuring a Storage-Compute Decoupled Cluster (Agency)**. The **MRS_ECS_DEFAULT_AGENCY** agency has the OBS OperateAccess permission of OBS and the CES FullAccess (for users who have enabled fine-grained policies), CES Administrator, and KMS Administrator permissions in the region where the cluster is located.
OBS Permission Control	Click **Manage** and modify the mapping between MRS users and OBS permissions. For details, see **Configuring Fine-Grained Permissions for MRS Multi-User Access to OBS**.
Logging	Used to collect logs about cluster creation and scaling failures.
Secure Communications	Used to display the security authorization status. You can click  to enable or disable security authorization. Disabling security authorization brings high risks. Exercise caution when performing this operation. For details, see **Communication Security Authorization**.

On the cluster details page, click **Nodes**. For details about the node parameters, see **Table 5-9**.

Table 5-9 Node information

Parameter	Description
Configure Task Node	Used to add a Task node. For details, see **Adding a Task Node**. This operation applies only to the analysis cluster, streaming cluster, and hybrid cluster.
Add Node Group	Used to add node groups. This method applies only to customized clusters. For details, see **Adding a Node Group**.
Node Group	Node group name.

Parameter	Description
Node Type	Node type: • **Master**: A Master node in an MRS cluster manages the cluster, assigns MapReduce executable files to Core nodes, traces the execution status of each job, and monitors the DataNode running status. • A task node group is a group of nodes where only data roles that do not store data are deployed. The roles include NodeManager, ThriftServer, Thrift1Server, RESTServer, Supervisor, LogViewer, HBaseIndexer, and TagSync. • If other roles are deployed in the node group in addition to the preceding roles, the node group is the Core node group. On the **Nodes** tab page, click ⌄ next to a node group name to unfold the nodes contained in the node group. Click a node name to remotely log in to the ECS using the password or key pair configured during cluster creation. For details about the parameters, see **Managing Components and Monitoring Hosts**.
Node Count	Number of nodes in a node group.
Operation	• **Scale Out**: For details, see **Scaling Out a Cluster**. • **Scale In**: For details, see **Scaling In a Cluster**. • **Delete**: To delete a node group, ensure that there is no node in the node group. • **View Roles**: You can view information about roles deployed on the node group. This function applies only to custom clusters of 3.x and later.

5.2.4 Managing Components and Monitoring Hosts

You can manage the following status and metrics of all components (including role instances) and hosts on the MRS console:

- Status information: includes operation, health, configuration, and role instance status.
- Indicator information: includes key monitoring indicators for each component.

NOTE

- You can set the interval for automatically refreshing the page or click ↻ to refresh the page immediately.
- Component management supports the following parameter values:
  - Refresh every 30 seconds
  - Refresh every 60 seconds
  - Stop refreshing

Prerequisites

You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Manage components.

Step 1 On the MRS cluster details page, click **Components**.

- **Table 5-10** describes the service operating status.

  Table 5-10 Service operating status

Status	Description
Started	The service is started.
Stopped	The service is stopped.
Failed to start	Failed to start the role instance.
Failed to stop	Failed to stop the service.
Unknown	Indicates initial service status after the background system restarts.

- **Table 5-11** describes the service health status.

  Table 5-11 Service health status

Status	Description
Good	Indicates that all role instances in the service are running properly.
Faulty	Indicates that the running status of at least one role instance is **Faulty** or the status of the service on which the current service depends is abnormal.
Unknown	Indicates that all role instances in the service are in the **Unknown** state.
Restoring	Indicates that the background system is restarting the service.
Partially Healthy	Indicates that the status of the service on which the service depends is abnormal, and APIs related to the abnormal service cannot be invoked by external systems.

- **Table 5-12** describes the service health status.

Table 5-12 Service configuration status

Status	Description
Synchronized	The latest configuration takes effect.
Configuration expired	The latest configuration does not take effect after the parameter modification. Related services need to be restarted.
Configuration failed	The communication is incorrect or data cannot be read or written during the parameter configuration. Use **Synchronize Configuration** to rectify the fault.
Configuring	Parameters are being configured.
Unknown	Indicates that configuration status cannot be obtained.

Step 2 Click a specified service in the list to view its status and metric information.

Step 3 Customize and view monitoring graphs.

1. In the **Charts** area, click **Customize** to customize service monitoring metrics.
2. In **Period** area, select a time of period and click **View** to view the monitoring data within the time period.

----End

Manage role instances.

Step 1 On the MRS cluster details page, click **Components**. In the component list, click the specified service name.

Step 2 Click **Instances** to view the role status.

The role instance list contains the Role, Host Name, Management IP Address, Service IP Address, Rack, Running Status, and Configuration Status of each instance.

- **Table 5-13** shows the running status of a role instance.

Table 5-13 Role instance running status

Status	Description
Good	Indicates that the instance is running properly.
Bad	Indicates that the instance cannot run properly.
Decommissioned	Indicates that the instance is out of service.
Not started	Indicates that the instance is stopped.
Unknown	Indicates that the initial status of the instance cannot be detected.

Status	Description
Starting	Indicates that the instance is being started.
Stopping	Indicates that the instance is being stopped.
Restoring	Indicates that an exception may occur in the instance and the instance is being automatically rectified.
Decommissioning	Indicates that the instance is being decommissioned.
Recommissioning	Indicates that the instance is being recommissioned.
Failed to start	Indicates that the service fails to be started.
Failed to stop	Indicates that the service fails to be stopped.

- Table 5-14 shows the configuration status of a role instance.

  Table 5-14 Role instance configuration status

Status	Description
Synchronized	The latest configuration takes effect.
Configuration expired	The latest configuration does not take effect after the parameter modification. Related services need to be restarted.
Configuration failed	The communication is incorrect or data cannot be read or written during the parameter configuration. Use **Synchronize Configuration** to rectify the fault.
Configuring	Parameters are being configured.
Unknown	Current configuration status cannot be obtained.

By default, the **Role** column is sorted in ascending order. You can click the sorting icon next to **Role**, **Host Name**, **OM IP Address**, **Business IP Address**, **Rack**, **Running Status**, or **Configuration Status** to change the sorting mode.

You can filter out all instances of the same role in the **Role** column.

You can set search criteria in the role search area by clicking **Advanced Search**, and click **Search** to view specified role information. You can click **Reset** to reset the search criteria. Fuzzy search is supported.

Step 3 Click the target role instance to view its status and metric information.

Step 4 Customize and view monitoring graphs.

1. In the **Charts** area, click **Customize** to customize service monitoring metrics.
2. In **Period** area, select a time of period and click **View** to view the monitoring data within the time period.

----End

Manage hosts.

Step 1 On the MRS cluster details page, click the **Nodes** tab and expand a node group to view the host status.

The host list of a group contains the **Node Name/Resource ID**, **IP**, **Status**, **Specifications**, **Disks**, and **AZ**.

- **Table 5-15** shows the host operating status.

  Table 5-15 Host operating status

Status	Description
Normal	The host and service roles on the host are running properly.
Isolated	The host is isolated, and the service roles on the host stop running.

- **Table 5-16** describes the host health status.

  Table 5-16 Host health status

Status	Description
Good	The host can properly send heartbeats.
Bad	The host fails to send heartbeats due to timeout.
Unknown	The host initial status is unknown during the operation of adding or deleting a host.

By default, data is sorted in ascending order by node name. You can click to change the order.

Step 2 Click the target node in the list to view its status and metric information.

----End

5.3 Viewing and Customizing Cluster Monitoring Metrics

MRS cluster nodes are classified into management nodes, control nodes, and data nodes. The change trends of key host monitoring metrics on each type of node can be calculated and displayed as curve charts in reports based on the customized periods. If a host belongs to multiple node types, the metric statistics will be repeatedly collected.

This section provides overview of MRS clusters and describes how to view, customize, and export node monitoring metrics on MRS Manager.

NOTE

Cluster metrics are monitored periodically. The average historical monitoring interval is about 5 minutes.

1. Log in to the MRS console.
2. Choose **Clusters** > **Active Clusters** and click a cluster name to access its details page.
3. On the **Dashboard** tab page, click **Click to synchronize** next to **IAM User Sync** to synchronize IAM users.
4. After the synchronization is complete, you can view the cluster monitoring metric report on the right of the page.
5. In time range area, specify a period to view monitoring data. The options are as follows:
   - Last 1 hour
   - Last 3 hours
   - Last 12 hours
   - Last 24 hours
   - Recent 7 days
   - Recent 30 days
   - Customize: You can customize the period for viewing monitoring data.
6. Customize a monitoring metric report.
   a. Click **Customize** and select monitoring metrics to be displayed.
   b. Click **OK** to save the selected monitoring metrics for display.

      NOTE

      Click **Clear** to cancel all the selected monitoring metrics in a batch.

5.4 Cluster O&M

5.4.1 Importing and Exporting Data

Through the **Files** tab page, you can create, delete, import, export, delete files in the analysis cluster. Currently, file creation is not supported. Streaming clusters do not support the file management function on the MRS GUI. In a cluster with Kerberos authentication enabled, to read or write the folders in the root directory, add a role that has the required permissions on the folders by referring to **Managing Roles**. Then, add the new role to the user group to which the user who submits the job belongs by referring to **Creating a User**.

Background

Data sources processed by MRS are from OBS or HDFS. OBS is an object-based storage service that provides you with massive, secure, reliable, and cost-effective data storage capabilities. MRS can process data in OBS directly. You can view, manage, and use data by using the web page of the management control platform or OBS client. In addition, you can use REST APIs independently or integrate APIs to service applications to manage and access data.

Before creating jobs, upload the local data to OBS for MRS to compute and analyze. MRS allows exporting data from OBS to HDFS for computing and analyzing. After the data analysis and computing are completed, you can store the data in HDFS or export them to OBS. HDFS and OBS can also store the compressed data in the format of **bz2** or **gz**.

Importing Data

Currently, MRS can only import data from OBS to HDFS. The file upload rate decreases with the increase of the file size. This mode applies to scenarios where the data volume is small.

You can perform the following steps to import files and directories:

1. Log in to the MRS console.
2. Choose **Clusters > Active Clusters** and click the name of the cluster to be queried to enter the page displaying the cluster's information.
3. Click the **Files** tab, and go to the file management page.
4. Select **HDFS File List**.
5. Go to the data storage directory, for example, **bd_app1**.

   The **bd_app1** directory is only an example. You can use any directory on the page or create a new one.

   The requirements for creating a folder are as follows:

   - The folder name contains a maximum of 255 characters
   - The folder name cannot be empty.
   - The folder name cannot contain the following special characters: /:*?"<>|\;&,'`!{}[]$%+
   - The value cannot start or end with a period (.).
   - The spaces at the beginning and end are ignored.
6. Click **Import Data** and configure the HDFS and OBS paths correctly. When configuring the OBS or HDFS path, click **Browse**, select a file directory, and click **Yes**.
   - OBS path
     - The path must start with **obs://**.
     - Files or programs encrypted by KMS cannot be imported.
     - An empty folder cannot be imported.
     - The directory and file name can contain letters, digits, hyphens (-), and underscores (_), but cannot contain the following special characters ;|&>,<'$*?\
     - The directory and file name cannot start or end with a space, but can contain spaces between them.
     - The OBS full path contains a maximum of 255 characters.
   - HDFS path

- The path starts with **/user** by default.
- The directory and file name can contain letters, digits, hyphens (-), and underscores (_), but cannot contain the following special characters: ;|&>,<'$*?\:
- The directory and file name cannot start or end with a space, but can contain spaces between them.
- The HDFS full path contains a maximum of 255 characters.

7. Click **OK**.

   You can view the file upload progress on the **File Operation Records** tab page. MRS processes the data import operation as a DistCp job. You can also check whether the DistCp job is successfully executed on the **Jobs** tab page.

Exporting Data

After the data analysis and computing are completed, you can store the data in HDFS or export them to OBS.

You can perform the following steps to export files and directories:

1. Log in to the MRS console.
2. Choose **Clusters > Active Clusters** and click the name of the cluster to be queried to enter the page displaying the cluster's basic information.
3. Click the **Files** tab, and the file management page is displayed.
4. Select **HDFS File List**.
5. Go to the data storage directory, for example, **bd_app1**.
6. Click **Export Data** and configure the OBS and HDFS paths. When configuring the OBS or HDFS path, click **Browse**, select a file directory, and click **Yes**.
   - OBS path
     - The path must start with **obs://**.
     - The directory and file name can contain letters, digits, hyphens (-), and underscores (_), but cannot contain the following special characters: ;|&>,<'$*?\
     - The directory and file name cannot start or end with a space, but can contain spaces between them.
     - The OBS full path contains a maximum of 255 characters.
   - HDFS path
     - The path starts with **/user** by default.
     - The directory and file name can contain letters, digits, hyphens (-), and underscores (_), but cannot contain the following special characters: ;|&>,<'$*?\:
     - The directory and file name cannot start or end with a space, but can contain spaces between them.

- The HDFS full path contains a maximum of 255 characters.

NOTE

When a folder is exported to OBS, a label file named **folder name_$folder$** is added to the OBS path. Ensure that the exported folder is not empty. If the exported folder is empty, OBS cannot display the folder and only generates a file named **folder name_$folder$**.

7. Click **OK**.

   You can view the file upload progress on the **File Operation Records** tab page. MRS processes the data export operation as a DistCp job. You can also check whether the DistCp job is successfully executed on the **Jobs** tab page.

Viewing Operation Logs

When importing and exporting data on the MRS management console, you can choose **Files** > **File Operation Records** to view the data import and export progress.

Table 5-17 describes the parameters of the file operation record.

Table 5-17 File operation record parameters

Parameter	Description
Created	Time when the data import or export task is created.
Source Path	Source path of data. • OBS path during data import. • HDFS path during data export.
Target Path	Target path of data. • HDFS path during data import. • OBS path during data import.
Status	Status during data import or export. • Submitted • Accepted • Running • Completed • Terminated • Abnormal
Duration (min)	Time of data import or export. The unit is minute.

Parameter	Description
Result	Result of data import or export. • Successful • Failed • Killed • Undefined
Operation	View Log: allows you to view file operation logs.

5.4.2 Changing the Subnet of a Cluster

If the current subnet does not have sufficient IP addresses, you can change to another subnet in the same VPC of the current cluster to obtain more available subnet IP addresses. Changing a subnet does not affect the IP addresses or subnets of existing nodes.

For details about how to configure network ACL outbound rules, see **How Do I Configure a Network ACL Outbound Rule?**

Changing a Subnet When No Network ACL Is Associated

Step 1 Log in to the MRS console.

Step 2 Click the target cluster name to go to its details page.

Step 3 Click **Change Subnet** on the right of **Default Subnet**.

Step 4 Select the target subnet and click **OK**.

If no subnet is available, click **Create Subnet** to create a subnet first.

----End

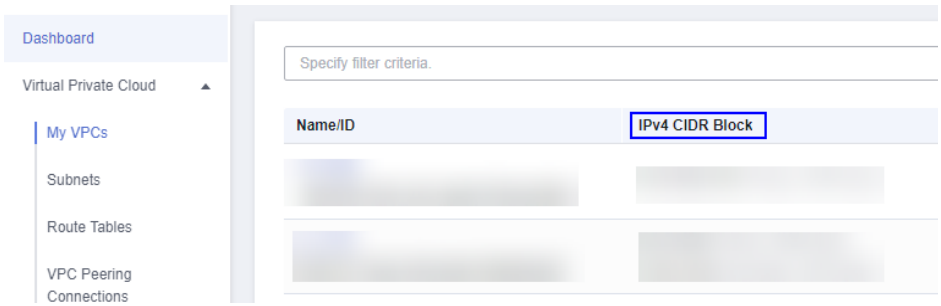
Changing a Subnet When a Network ACL Is Associated

Step 1 Log in to the MRS console and click the target cluster to go to its details page.

Step 2 In the **Basic Information** area, view **VPC**.

Step 3 Log in to the VPC console. In the navigation pane on the left, choose **Virtual Private Cloud** and obtain the IPv4 CIDR block corresponding to the VPC obtained in **Step 2**.

Figure 5-3 Obtaining the IPv4 CIDR block

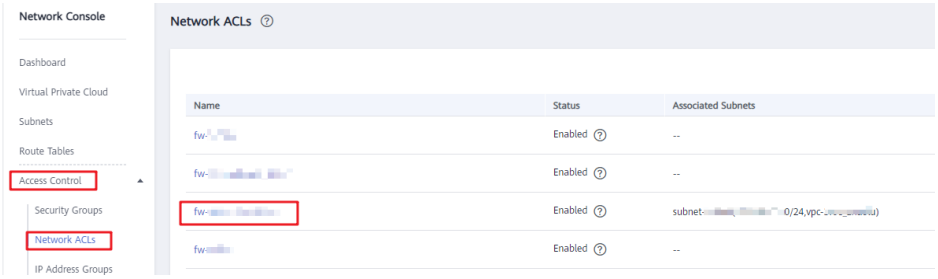


Step 4 Choose **Access Control** > **Network ACLs** and click the name of the network ACL that is associated with the default and new subnets.

NOTE

If both the default and new subnets are associated with a network ACL, add inbound rules to the network ACL by referring to **Step 5** to **Step 7**.

Figure 5-4 Network ACLs



Step 5 On the **Inbound Rules** page, choose **More** > **Insert Rule Above** in the **Operation** column.

Step 6 Add a network ACL rule. Set **Action** to **Allow**, **Source** to the VPC IPv4 CIDR block obtained in **Step 3**, and retain the default values for other parameters.

Step 7 Click **OK**.

NOTE

If you do not want to allow access from all IPv4 CIDR blocks of the VPC, add the IPv4 CIDR blocks of the default and new subnets by performing **Step 8** to **Step 12**. If the rules for VPC IPv4 CIDR blocks have been added, skip **Step 8** to **Step 12**.

Step 8 Log in to the MRS console.

Step 9 Click the target cluster to go to its details page.

Step 10 Click **Change Subnet** on the right of **Default Subnet**.

Step 11 Obtain the IPv4 CIDR blocks of the default and new subnets.

NOTICE

In this case, you do not need to click **OK** displayed in the **Change Subnet** dialog box. Otherwise, the default subnet will be updated to the new subnet, thereby making it difficult to query the IPv4 CIDR block of the default subnet. Exercise caution when performing this operation.

Step 12 Add the IPv4 CIDR blocks of the default and target subnets to the inbound rules of the network ACL bound to the two subnets by referring to **Step 4** to **Step 7**.

Step 13 Log in to the MRS console.

Step 14 Click the target cluster to go to its details page.

Step 15 Click **Change Subnet** on the right of **Default Subnet**.

Step 16 Select the target subnet and click **OK**.

----End

How Do I Configure a Network ACL Outbound Rule?

- Method 1

  Allow all outbound traffic. This method ensures that clusters can be created and used properly.

- Method 2

  Allow the mandatory outbound rules that can ensure the successful creation of clusters. You are not advised to use this method because created clusters may not run properly due to absent outbound rules. If the preceding problem occurs, contact O&M personnel.

  Similar to the example provided in method 1, set **Action** to **Allow** and add the outbound rules whose destinations are the address with **Secure Communications** enabled, NTP server address, OBS server address, OpenStack address, and DNS server address, respectively.

5.4.3 Configuring Message Notification

MRS uses SMN to offer a publish/subscribe model to achieve one-to-multiple message subscriptions and notifications in a variety of message types (SMSs and emails).

Scenario

On the MRS management console, you can enable or disable the notification service on the **Alarms** page. The functions in the following scenarios can be implemented only after the required cluster function is enabled:

- After a user subscribes to the notification service, the MRS management plane notifies the user of success or failure of manual cluster scale-out and scale-in, cluster deletion, and auto scaling by emails or SMS messages.
- The management plane checks the alarms about the MRS cluster and sends a notification to the tenant if the alarms are critical.
- If either of the operations such as deletion, shutdown, specifications modification, restart, and OS update is performed on an ECS in a cluster, the MRS cluster works abnormally. The management plane notifies a user when detecting that the VM of the user is in either of the preceding operations.

Creating a Topic

A topic is a specified event for message publication and notification subscription. It serves as a message sending channel, where publishers and subscribers can interact with each other.

1. Log in to the management console.
2. Click **Service List**. Under **Management & Governance**, click **Simple Message Notification**.

   The **SMN** page is displayed.

3. In the navigation pane, choose **Topic Management** > **Topics**.

   The **Topics** page is displayed.

4. Click **Create Topic**.

   The **Create Topic** dialog box is displayed.

5. In **Topic Name**, enter a topic name. In **Display Name**, enter a display name.
6. Select an existing project from the **Enterprise Project** drop-down list, or click **Create Enterprise Project** to create an enterprise project on the **Enterprise Project Management** page and then select it.
7. Set tag keys and tag values. Tags consist of keys and values. They identify cloud resources so that you can easily categorize and search for your resources.

Adding Subscriptions to a Topic

To deliver messages published to a topic to subscribers, you must add subscription endpoints to the topic. SMN automatically sends a confirmation message to the subscription endpoint. The confirmation message is valid only within 48 hours. The subscribers must confirm the subscription within 48 hours so that they can receive notification messages. Otherwise, the confirmation message becomes invalid, and you need to send it again.

1. Log in to the management console.
2. Under **Management & Governance**, click **Simple Message Notification**.

   The **SMN** page is displayed.

3. In the navigation pane, choose **Topic Management** > **Topics**.

   The **Topics** page is displayed.

4. Locate the topic to which you want to add a subscription, click **More** in the **Operation** column, and select **Add Subscription**.

   The **Add Subscription** box is displayed.

   Protocol can be set to **SMS**, FunctionGraph (function), **HTTP**, **HTTPS**, and **Email**.

   Endpoint indicates the address of the subscription endpoint. SMS and email, endpoints can be entered in batches. When adding endpoints in batches, each endpoint address occupies a line. You can enter a maximum of 10 endpoints.

5. Click **OK**.

The subscription you added is displayed in the subscription list.

Sending Notifications to Subscribers

1. Log in to the MRS console.
2. Choose **Clusters > Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.
3. Click **Alarms**.
4. Choose **Notification Rules** > **Add Notification Rule**. The **Add Notification Rule** page is displayed.
5. Set the notification rule parameters.

Table 5-18 Parameters of a notification rule

Parameter	Description
Rule Name	User-defined notification rule name. Only digits, letters, hyphens (-), and underscores (_) are allowed.
Message Notification	• If you enable this function, the system sends notifications to subscribers based on the notification rule. • If you disable this function, the rule does not take effect, that is, notifications are not sent to subscribers.
Topic Name	Select an existing topic or click **Create Topic** to create a topic.
Notification Type	Select the type of the notification to be subscribed to. • Alarm • Event
Subscription Items	Select the items to be subscribed to. You can select all or some items as required. Alarm severity: critical, major, and minor Event: major, minor, and warning

6. Click **OK**.

5.4.4 Remote O&M

5.4.4.1 Authorizing O&M

If you need technical support personnel to help you with troubleshooting, you can use the O&M authorization function to authorize technical support personnel to access your local host for fault location.

Procedure

Step 1 Log in to the MRS management console.

Step 2 In the navigation tree of the MRS management console, choose **Clusters** > **Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.

Step 3 In the upper right corner of the page, click **O&M**, choose **Authorize for Cluster Nodes**, and select the deadline for the support personnel to access the local host.

Before the deadline, the support personnel have the temporary permission to access the local host.

Step 4 After the fault is rectified, click **O&M** in the upper right corner of the page and choose **Cancel Cluster Node Authorization** to retrieve the access permission granted to the support personnel.

----End

5.4.4.2 Sharing Logs

If you need technical support personnel to help you with troubleshooting, you can use the log sharing function to provide logs in a specific time to technical support personnel for fault location.

Procedure

Step 1 Log in to the MRS management console.

Step 2 In the navigation tree of the MRS management console, choose **Clusters** > **Active Clusters**, select a cluster, and click its name to switch to the cluster details page.

Step 3 In the upper right corner of the displayed page, choose **O&M** > **Share Log** to open the **Share Log** dialog box.

Step 4 Select the start time and end time in **Time Range**.

NOTE

- Select **Time Range** based on the suggestions of support personnel.
- **End Date** must be later than **Start Date**. Otherwise, logs cannot be filtered by time.

----End

5.4.5 Viewing MRS Operation Logs

You can view operation logs of clusters and jobs on the **Operation Logs** page. Log information is typically used for quickly locating faults in case of cluster exceptions, helping users resolve problems.

Operation Type

Currently, the following operation logs are provided by MRS. You can filter the logs in the search box.

- Cluster operations
  - Creating, deleting, scaling out, and scaling in a cluster
  - Creating and deleting a directory, deleting a file
- Job operations: Creating, stopping, and deleting a job
- Data operations: IAM user tasks, adding user, and adding user group

Log Fields

Logs are listed in chronological order by default in the log list, with the most recent logs displayed at the top.

Table 5-19 describes various fields in a log.

Table 5-19 Log description

Parameter	Description
Operation Type	Various types of operations, including: • Cluster operations • Job operations • Data operations
Operation IP	IP address where an operation is performed. **NOTE** If an MRS cluster fails to be deployed, the cluster is automatically deleted, and the operation logs of the automatically deleted cluster do not contain the **Operation IP** of the user.
Operation	Operation details. The value can contain a maximum of 2048 characters.
Time	Operation time. For a deleted cluster, only logs generated within the last six months are displayed. To view logs generated six months ago, contact technical support.
Enterprise Project	Enterprise project to which the cluster belongs

Table 5-20 Icon description

Icon	Description
	Select an enterprise project from the drop-down list box to filter logs.
	Select an operation type from the drop-down list box to filter logs. • **All Operation Types**: Filter all logs. • **Cluster**: Filter logs for **Cluster**. • **Job**: Filter logs for **Job**. • **Data**: Filter logs for **Data**.
	Filter logs by time. 1. Click the input box. 2. Specify the date and time. 3. Click **OK**. The left-side input box indicates the start time and the right-side one indicates the end time. The start time must be earlier than or equal to the end time. Otherwise, logs cannot be filtered.

Icon	Description
	Enter a keyword of the **Operation Details** in the search box and click  to search for logs.
	Click  to manually refresh the log list.

5.4.6 Deleting a Cluster

You can delete an MRS cluster after job execution is complete.

Background

You can manually delete a cluster after data analysis is complete or when the cluster encounters an exception. A cluster failed to be deployed will be automatically deleted.

Procedure

Step 1 Log in to the MRS management console.

Step 2 In the navigation pane on the left, choose **Clusters** > **Active Clusters**.

Step 3 In the cluster list, locate the row containing the cluster to be deleted, and click **Delete** in the **Operation** column.

The cluster status changes from **Running** to **Deleting**, and finally to **Deleted**. You can view the deleted cluster in **Cluster History**.

----End

5.5 Managing Nodes

5.5.1 Scaling Out a Cluster

The storage and computing capabilities of MRS can be improved by simply adding Core nodes or Task nodes instead of modifying system architecture, reducing O&M costs. Core nodes can process and store data. You can add Core nodes to expand the node quantities and handle peak loads. Task nodes are used for computing and do not store persistent data.

Background

The MRS cluster supports a maximum of 500 core and task nodes. If more than 500 core/task nodes are required, contact technical support or call a background interface to modify the database.

Only core and task nodes can be added. The maximum number of core/task nodes to be added is 500 minus the number of core/task nodes in the cluster. For example, the current number of Core nodes is 3, the number of Core nodes to be

added must be less than or equal to 497. If the cluster scale-out fails, you can add node to the cluster again.

If no node is added during cluster creation, you can specify the number of nodes to be added during scale-out. However, you cannot specify the nodes to be added.

The operations for scaling out a cluster vary depending on the selected version.

Constraints

- When you expand a node group where HBase is installed:

  If automatic DNS registration is not enabled for a node in the cluster, do not start HBase when you expand the node group. Then, update the HBase client configuration by referring to **Updating the Client Configuration** and start the HBase instances on the node to be expanded.
- After a scale-out, the clients installed on nodes in the cluster do not need to be updated. For details about how to update the client installed on nodes outside the cluster, see **Updating the Client Configuration**.

Procedure

Step 1 Log in to the MRS console.

Step 2 Choose **Clusters** > **Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.

Step 3 Click the **Nodes** tab. In the **Operation** column of the node group, click **Scale Out**. The **Scale Out** page is displayed.

The scale-out operation can only be performed on the running clusters.

Step 4 Set **Scaled Out Nodes**, **Enable Component**, and **Run Bootstrap Action**, and click **OK**

NOTE

- If the Task node group does not exist in the cluster, configure the Task node by referring to **Adding a Task Node**.
- If a bootstrap action is added during cluster creation, the **Run Bootstrap Action** parameter is valid. If this function is enabled, the bootstrap actions added during cluster creation will be run on all the scaled out nodes.
- If the **New Specifications** parameter is available, the specifications that are the same as those of the original nodes have been discontinued. Nodes with new specifications will be added.
- Before scaling out the cluster, check whether its security group configuration is correct. Ensure that an inbound security group rule contains a rule in which **Protocol & Port** is set to **All**, and **Source** is set to a trusted accessible IP address range.

Step 5 In the **Scale Out Node** dialog box, click **OK**.

Step 6 A dialog box is displayed, indicating that the scale-out task is submitted successfully.

The following parameters explain the cluster scale-out process:

- Expanding: If a cluster is being expanded, its status is **Scaling out**. The submitted jobs will be executed and you can submit new jobs. You are not allowed to continue to scale out or delete the cluster. You are advised not to restart the cluster or modify the cluster configuration.

- Expansion succeeded: If a cluster is expanded successfully, its status is **Running**.
- Failed scale-out: The cluster status is **Running** when the cluster scale-out failed. You can execute jobs and scale out the cluster again.

After the cluster is scaled out, you can view the node information of the cluster on the **Nodes** page.

----End

Adding a Task Node

You can scale out an MRS cluster by manually adding task nodes.

To add a task node to a custom cluster, perform the following steps:

1. On the cluster details page, click the **Nodes** tab and click **Add Node Group**. The **Add Node Group** page is displayed.
2. Select **Task** for**Node Type**. Retain the default value **NM** for **Deploy Roles**. To deploy the NodeManager role, the node type must be **Task**. Set other parameters as required.

To add a task node to a non-custom cluster, perform the following steps:

1. On the cluster details page, click the **Nodes** tab and click **Configure Task Node**. The **Configure Task Node** page is displayed.
2. On the **Configure Task Node** page, set **Node Type**, **Instance Specifications**, **Nodes**, **System Disk**. In addition, if **Add Data Disk** is enabled, configure the storage type, size, and number of data disks.
3. Click **OK**.

Adding a Node Group

NOTE

Used to add node groups and applies to customized clusters of MRS 3.*x*.

1. On the cluster details page, click the **Nodes** tab and click **Add Node Group**. The **Add Node Group** page is displayed.
2. Set the parameters as needed.

Table 5-21 Parameters for adding a node group

Parameter	Description
Instance Specifications	Select the flavor type of the hosts in the node group.
Nodes	Set the number of nodes in the node group.
System Disk	Set the specifications and capacity of the system disk on the new node.

Parameter	Description
Data Disk (GB)	Set the specifications, capacity, and number of data disks of the new node.
Deploy Roles	Deploy the instances of each node in the new node group. The setting can be manually adjusted.

3. Click **OK**.

5.5.2 Scaling In a Cluster

You can reduce the number of core or task nodes to scale in a cluster based on service requirements so that MRS delivers better storage and computing capabilities at lower O&M costs.

The scale-in operation is not allowed for a cluster that is performing active/standby synchronization.

Background

A cluster can have three types of nodes, master, core, and task nodes. Currently, only core and task nodes can be removed. To scale in a cluster, you only need to adjust the number of nodes on the MRS console. MRS then automatically selects the nodes to be removed.

The policies for MRS to automatically select nodes are as follows:

- MRS does not select the nodes with basic components installed, such as ZooKeeper, DBService, KrbServer, and LdapServer, because these basic components are the basis for the cluster to run.
- Core nodes store cluster service data. When scaling in a cluster, ensure that all data on the core nodes to be removed has been migrated to other nodes. You can perform follow-up scale-in operations only after all component services are decommissioned, for example, removing nodes from Manager and deleting ECSs. When selecting core nodes, MRS preferentially selects the nodes with a small amount of data and healthy instances to be decommissioned to prevent decommissioning failures. For example, if DataNodes are installed on core nodes in an analysis cluster, MRS preferentially selects the nodes with small data volume and good health status during scale-in.

  When core nodes are removed, their data is migrated to other nodes. If the user business has cached the data storage path, the client will automatically update the path, which may increase the service processing latency temporarily. Cluster scale-in may slow the response of the first access to some HBase on HDFS data. You can restart HBase or disable or enable related tables to resolve this issue.
- Task nodes are computing nodes and do not store cluster data. Data migration is not involved in removing task nodes. Therefore, when selecting task nodes, MRS preferentially selects nodes whose health status is faulty, unknown, or subhealthy. On the **Components** tab of the MRS console, click a service and then the **Instances** tab to view the health status of the node instances.

Scale-In Verification Policy

To prevent component decommissioning failures, components provide different decommissioning constraints. Scale-in is allowed only when the constraints of all installed components are met. **Table 5-22** describes the scale-in verification policies.

Table 5-22 Decommissioning constraints

Component	Constraint
HDFS/DataNode	The number of available nodes after the scale-in is greater than or equal to the number of HDFS copies and the total HDFS data volume does not exceed 80% of the total HDFS cluster capacity. This ensures that the remaining space is sufficient for storing existing data after the scale-in and reserves some space for future use. **NOTE** To ensure data reliability, one backup is automatically generated for each file saved in HDFS, that is, two copies are generated in total.
HBase/ RegionServer	The total available memory of RegionServers on all nodes except the nodes to be removed is greater than 1.2 times of the memory which is currently used by RegionServers on these nodes. This ensures that the node to which the region on a decommissioned node is migrated has sufficient memory to bear the region of the decommissioned node.
Storm/ Supervisor	After the scale-in, ensure that the number of slots in the cluster is sufficient for running the submitted tasks. This prevents no sufficient resources being available for running the stream processing tasks after the scale-in.
Flume/ FlumeServer	If FlumeServer is installed on a node and Flume tasks have been configured for the node, the node cannot be deleted. This prevents the deployed service program from being deleted by mistake.
ClickHouse/ ClickHouseServer	For details, see **Constraints on ClickHouseServer Scale-in**. This ensures that data on the decommissioned nodes is migrated to in-use nodes.

Scaling In a Cluster by Specifying the Node Quantity

Step 1 Log in to the MRS console.

Step 2 Choose **Clusters** > **Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.

Step 3 Click the **Nodes** tab. In the **Operation** column of the node group, click **Scale In** to go to the **Scale In** page.

This operation can be performed only when the cluster and all nodes in it are running.

Step 4 Set **Scale-In Type** to **Node quantity**.

Step 5 Set **Scale-In Nodes** and click **OK**.

NOTE

- Before scaling in the cluster, check whether its security group configuration is correct. Ensure that an inbound security group rule contains a rule in which **Protocol & Port** is set to **All**, and **Source** is set to a trusted accessible IP address range.
- If damaged data blocks exist in HDFS, the cluster may fail to be scaled in. Contact technical support.

Step 6 A dialog box displayed in the upper right corner of the page indicates that the task of removing the node is submitted successfully.

The cluster scale-in process is explained as follows:

- During scale-in: The cluster status is **Scaling In**. The submitted jobs will be executed, and you can submit new jobs. You are not allowed to continue to scale in or delete the cluster. You are advised not to restart the cluster or modify the cluster configuration.
- Successful scale-in: The cluster status is **Running**.
- Failed scale-in: The cluster status is **Running**. You can execute jobs or scale-in the cluster again.

After the cluster is scaled in, you can view the node information of the cluster on the **Nodes** page.

----End

Scaling In a Cluster by Removing Nodes that Are No Longer Needed

If a faulty node is no longer needed, you can use this function to remove it. When the node is removed, the instance of the component role will not be decommissioned. Before deleting the node, ensure that the data on the node has been backed up. For details about how to remove ClickHouseServer nodes, see **Removing ClickHouseServer Instance Nodes**.

Step 1 Log in to MRS Manager and choose **Hosts**.

Step 2 Select the host to be removed, choose **More**, and select **Isolate** to isolate the host.

The time required for isolating a host depends on the data volume on the host. A larger data volume requires a longer time.

After the node is isolated, the node status changes to **Isolated**.

NOTE

- If the host isolation fails, log in to MRS Manager, click to search for the task that fails to isolate the host in the task list, and rectify the fault as prompted.
- Isolating a host helps you decommission a node. If data on the node has been backed up, you can skip the operation of isolating a host, directly stop the host on the ECS console, and scale in the host.
- If a host is faulty, forcibly remove the node.

Step 3 Log in to the MRS console.

Step 4 Click the name of the cluster to go to its details page.

Step 5 Click the **Nodes** tab.

Step 6 Locate the row that contains the target node group and click **Scale In** in the **Operation** column to go to the **Scale In** page.

Step 7 Set **Scale-In Type** to **Specific node** and select the node to be removed.

Nodes in the **Stopped**, **Lost**, **Unknown**, **Isolated**, or **Faulty** status can be specified for scale-in. If the node cannot be selected, click **Stop ECS** to go to the ECS console to stop the node. On the cluster details page of the MRS console, click the **Alarms** tab and check whether any service fault alarms are generated after the node is stopped. If no such an alarm is generated, go back to the **Scale In** page and select the corresponding node for scale-in. If such an alarm is generated, clear the alarm before the scale-in.

Step 8 Select **I understand the consequences of performing the scale-in operation**, and click **OK**.

Step 9 Click the **Components** tab and check whether each component is normal. If any component is abnormal, wait for 5 to 10 minutes and check the component status again. If the fault persists, contact technical support.

Step 10 Click the **Alarms** tab and check whether there are exception alarms. If there are exception alarms, clear them before performing other operations.

----End

5.5.3 Removing ClickHouseServer Instance Nodes

5.5.3.1 Constraints on ClickHouseServer Scale-in

Cluster Scale

- If a cluster has only one shard, the instance nodes cannot be removed from the cluster.
- Multiple instance nodes in the same shard **must be decommissioned or recommissioned at the same time**.

  To query cluster shard information, perform the following steps:

  a. Log in to the node where the client is installed as the client installation user.

cd *Client installation directory*

source bigdata_env

In security mode, run the following commands:

kinit *ClickHouse service user*

clickhouse client --host *IP address of the ClickHouse instance* **--port 9440 --secure**

In normal mode, run the following command:

clickhouse client --host *IP address of the ClickHouse instance* **--user** *Username* **--password --port** *9000*

Enter the password.

b. Run the following command to query the cluster shard information:

select cluster,shard_num,replica_num,host_name from system.clusters;

Cluster Storage

Ensure that the disk space of nodes that will not be decommissioned is sufficient for storing data of all decommissioned nodes. There must be approximately 10% redundant storage space after decommissioning to ensure that the remaining instances can run properly. The procedure is as follows:

1. Run the following command to check the disk usage on each node:

   select * from system.disks;

   free_space indicates the free disk space, and **total_space** indicates the total disk space. The used space is calculated by subtracting the value of **free_space** from that of **total_space**, and its unit is byte.

2. Run the preceding command on a node you want to decommission and calculate the data volume on the node using the preceding formula.
3. Run the preceding command on a node that will not be decommissioned, and then use the following formula: (Value of **free_space** – Data volume of the node to be decommissioned)/Value of **total_space**. If the result is greater than 10%, the node can be decommissioned.

Cluster Status

If there is any faulty ClickHouseServer instance node in the cluster, all instance nodes in the cluster cannot be decommissioned. Log in to Manager, choose **Cluster** > **Services** > **ClickHouse**, click **Instance**, and view the running status of each node in the cluster.

Database

If a database is deployed only on an instance node you want to decommission, the instance node cannot be decommissioned. To remove the instance node, you need to create the database on all ClickHouseServer instance nodes in the cluster. The procedure is as follows:

1. Run the **select * from system.databases;** command to collect the database list of each node.

name indicates the database name. **engine** indicates the database engine, and the default value is **Atomic**. If the default engine is used, you do not need to specify the engine when creating a table.

2. For the database deployed only on the instance node to be decommissioned, run the following command to create the database:

   create database xxx engine=xxx on cluster xxx;

Local Non-replicated Table

If a local non-replicated table is deployed only on an instance node you want to decommission, the instance node cannot be decommissioned. To decommission the node, create a local non-replicated table with the same name on any node that will not be decommissioned.

For example, the current cluster has two shards, shard 1 has two nodes A and B, and shard 2 has two nodes C and D. The non-replicated table **test** was created without the **ON CLUSTER** keyword, so the table is created only on node A.

In this case, to decommission nodes A and B in shard 1, you need to create the table **test** on node C or D in shard 2.

Run the following command to list the data tables of each node:

select database,name,engine,create_table_query from system.tables where database != 'system';

Perform the following operations according to the result:

- Check the **engine** column. The table that does not contain the **Replicated** field is a local non-replicated table.
- If there are no replicated tables on any nodes that will not be decommissioned, create one based the table created by **create_table_query**. The following creation statement is an example:

  CREATE TABLE {database}.{table} ('column name' type...) ENGINE = MergeTree;

Replicated Table

If a replicated table exists only on some nodes in the cluster, the nodes where the replicated table is deployed cannot be decommissioned. You need to manually create the replicated table on all instance nodes where no replicated table is deployed in the cluster before decommissioning.

For example, the current cluster has two shards, shard 1 has two nodes A and B, and shard 2 has two nodes C and D. The replicated table **test** was created without the **ON CLUSTER** keyword, so the table is created only on nodes A and B.

To decommission nodes A and B in shard 1, you need to create the table **test** on nodes C and D in shard 2.

Run the following command to list the data tables of each node:

select database,name,engine,create_table_query from system.tables where database != 'system';

Perform the following operations according to the result:

- Check the **engine** column. The table that contains the **Replicated** field is a replicated table.
- If there are no replicated tables on any nodes that will not be decommissioned, create one based the table created by **create_table_query**.

Distributed Table

Distributed tables will not be migrated automatically for decommissioning. Create distributed tables on the nodes that will not be decommissioned.

Run the following command to list data tables of each node and check the **engine** column. These tables are distributed tables if this column contains field **Distributed**.

select database,name,engine from system.tables where database != 'system';

NOTE

Creating distributed tables on these nodes will not affect the decommissioning, but may affect subsequent service operations.

View

Views will not be automatically migrated for decommissioning, and views do not store data. Run the following command to list data tables of each node and check the **engine** column. These tables are views if this column contains field **View**.

select database,name,engine from system.tables where database != 'system';

Run the following command to delete the views one by one:

drop view {database_name}.{table_name};

Materialized Views

Materialized views will not be automatically migrated for Decommissioning. Create materialized views on the nodes that will not be decommissioned. If the materialized view of a node to be decommissioned does not display the specified aggregation table but uses an embedded table, the node cannot be decommissioned.

Run the following command to list data tables of each node and check the **engine** column. These tables are materialized views if this column contains field **MaterializedView**.

select database,name,engine, create_table_query from system.tables where database != 'system';

The table whose **create_table_query** column contains the **POPULATE** field is an embedded table. Views are initialized when they are created, and newly inserted data is ignored during the initialization. A table that does not contain the **POPULATE** field is an aggregation table. Newly inserted data is directly inserted into the view charts and support tables, and the original data is manually loaded into the views and support tables. The table creation operations of the aggregation table and embedded table are different.

Perform the following operations to process the materialized views of the node to be decommissioned:

1. Record the materialized views and delete them.

   drop view {database_name}.{table_name};

2. After the node decommissioning is complete, delete and recreate the corresponding materialized views on in-use nodes to update the materialized views.
3. To create an aggregation table, specify **WHERE** to search for historical data and manually import the historical data to the materialized views. Otherwise, historical data cannot be imported to the materialized views based on unified conditions. As a result, data is imported repeatedly. For example, an update point can be specified to ensure that data before the update point is manually loaded in **INSERT** mode.
   - Add **WHERE** *{ Time field (for example, date)}***>= toDate (***{ Current time (for example, '2022-12-01 00:00:00')}***)** to the table creation statement.
   - **insert into** *{table}* **select** *{Table field}* **from** *{Source table}* **where** *{Time field}***< toDate** *({Current time})* is used to load original data.
4. Embedded tables will lose data generated during table creation. You can specify **WHERE** to filter out all historical data. In this case, an empty table is created, and you only need to manually insert all data in the historical data source table.

Tables of Third-Party Engines

Currently, tables of third-party engines cannot be automatically migrated for decommissioning.

Run the following command to list data tables of each node and check the **engine** column. These tables are tables of third-party engines if this column does not contain any of the following fields: **MergeTree**, **View**, **MaterializedView**, **Distributed**, and **Log**. (The **engine** column of a third-party engine table may contain field **Memory**, **HDFS**, or **MySQL**.)

select database,name,engine from system.tables where database != 'system';

Create third-party engine tables on the nodes that will not be decommissioned and delete those from the nodes that will be decommissioned.

Detached Data

If the table on a node to be decommissioned has been detached and data still exists in the **detached** directory, the node cannot be decommissioned. You need to attach the data in the **detached** directory to other directories before decommissioning.

1. Run the following command to view the **system.detached_parts** system catalog of the node to be decommissioned:

   select * from system.detached_parts;

2. If **detached part** data exists and these partitions are no longer used, run the following command to delete the **detached part** data:

   ALTER TABLE {table_name} DROP DETACHED PARTITION {partition_expr} SETTINGS allow_drop_detached = 1;

3. Run the following command to check whether there is any **detached part** data in the **system.detached_parts** system catalog:

   select * from system.detached_parts;

   If the command output is empty, there is no **detached part** data in this system catalog.

5.5.3.2 Scaling In ClickHouseServer Nodes

Before removing ClickHouseServer instance nodes, you need to decommission them. Multiple node replicas of the same shard **must be decommissioned at the same time**. If there is a faulty ClickHouseServer instance node in the cluster, all instance nodes of the cluster cannot be decommissioned. For more constraints, see **Constraints on ClickHouseServer Scale-in**.

NOTE

- Perform the decommissioning in idle hours because the operation will occupy certain bandwidth resources.
- The decommissioning operation can be performed only to ClickHouseServer. ClickHouseBalancer cannot be decommissioned.

Step 1 Use PuTTY to log in to the node where ClickHouseServer is installed as user **root** and run the following command:

echo 'select * from system.clusters' | curl -k 'https://*IP address of the node where the ClickHouseServer instance is located***:***Port number***/' -u** *ck_user*:*Password* **--data-binary @-**

Record the nodes of the same shard. In the following command output, the nodes with the same number in bold belong to the same shard.

```
[root@kwephispra44948 ~]# echo 'select * from  system.clusters' | curl -k 'https://10.112.17.189:21422/' -u ck_user:Bigdata_2013  --data-binary @-
default_cluster 1       1       1       kwephispra44947 10.112.17.150  21427   0                       0       0
default_cluster 1       1       2       kwephispra44948 10.112.17.189  21427   0                       0       0
```

NOTE

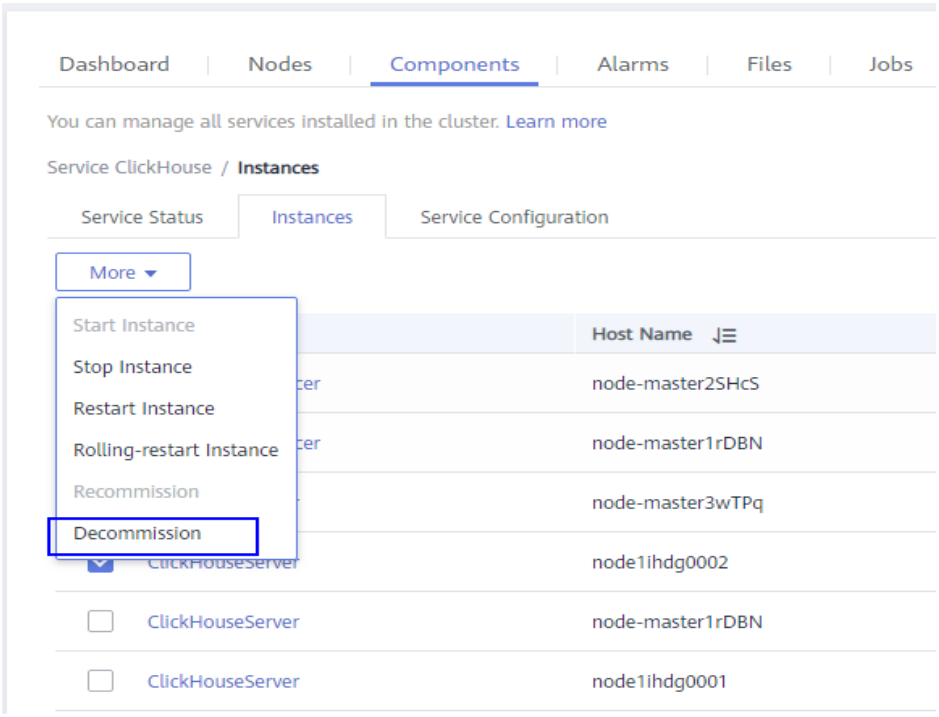
- To view the port number of ClickHouseServer instance nodes, log in to FusionInsight Manager, choose **Cluster** > **Services** > **ClickHouse**, click **Configuration** > **All Configurations**, and choose **ClickHouseServer (Role)** on the left.

  In security mode (Kerberos authentication enabled), check the value of **https_port**, which is the port of a ClickHouseServer instance node.

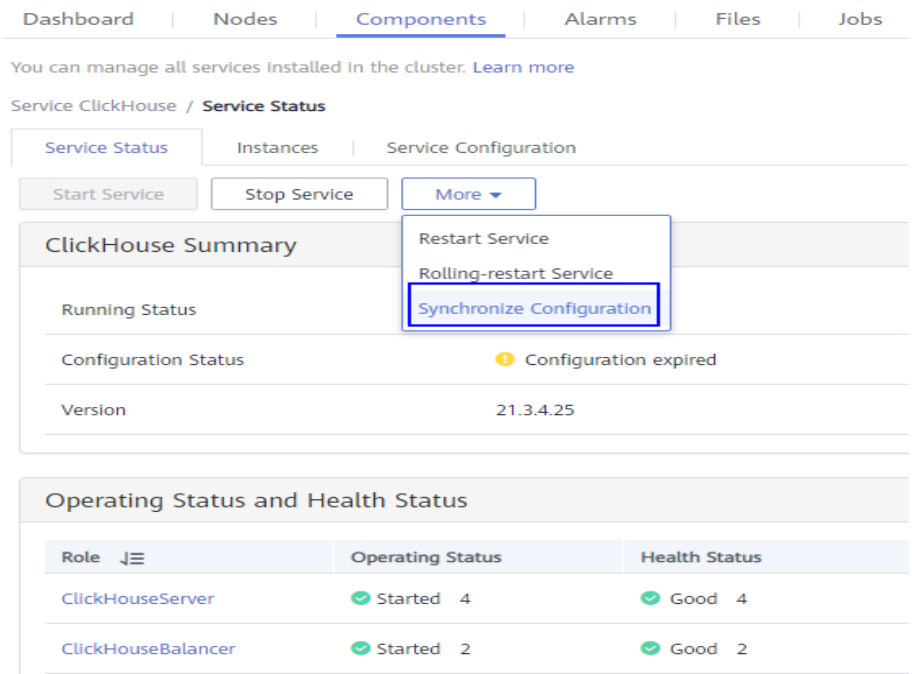
  In common mode (Kerberos authentication disabled), check the value of **http_port**, which is the port of a ClickHouseServer instance node.
- **ck_user** indicates the created ClickHouse user, which must be bound to a role with the ClickHouse administrator permission. For details about how to create a user and a role, see **Creating a User** and **Managing Roles**, respectively.

Step 2 Log in to the MRS console and click the cluster name to go to the cluster details page.

Step 3 Click the **Components** tab and click **ClickHouse**. Then switch to **Instances**, select the **ClickHouseServer** instances to be removed, click **More**, and select **Decommission**.



Step 4 Click the **Components** tab and click **ClickHouse**. Then click **More**, and select **Synchronize Configuration**.



Step 5 Click the **Nodes** tab and click the ClickHouseServer instance node that has been decommissioned.

Step 6 On the ECS page, click **Stop**. In the displayed dialog box, select **Forcibly stop the preceding ECSs** and click **Yes**.

Step 7 Go back to the MRS console, click the **Nodes** tab, locate the row that contains the target node group, and click **Scale In** in the **Operation** column to go to the **Scale In** page.

Step 8 Set **Scale-In Type** to **Specific node** and select the node to be removed.

Step 9 Select **I understand the consequences of performing the scale-in operation**. Click **OK**.

Step 10 Click the **Components** tab and check whether each component is normal. If any component is abnormal, wait for 5 to 10 minutes and check the component status again. If the fault persists, contact technical support.

Step 11 Click the **Alarms** tab and check whether there are exception alarms. If there are exception alarms, clear them before performing other operations.

----End

5.5.4 Managing a Host (Node)

Scenario

To check an abnormal or faulty host (node), you need to stop all host roles on MRS. To recover host services after the host fault is rectified, restart all roles.

Prerequisites

You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the MRS details page, click **Nodes**.

Step 2 Unfold the node group information and select the check box of the target node.

Step 3 Choose **Node Operation** > **Start All Roles** or **Stop All Roles** to perform the required operation.

----End

5.5.5 Isolating a Host

Scenario

If a host is found to be abnormal or faulty, affecting cluster performance or preventing services from being provided, you can temporarily exclude that host from the available nodes in the cluster. In this way, the client can access other available nodes. In scenarios where patches are to be installed in a cluster, you can also exclude a specified node from patch installation.

You can isolate a host manually on MRS based on the actual service requirements or O&M plan. Only non-management nodes can be isolated.

Impact on the System

- After a host is isolated, all role instances on the host will be stopped. You cannot start, stop, or configure the host and any instances on the host.
- After a host is isolated, statistics of the monitoring status and indicator data of the host hardware and instances cannot be collected or displayed.

Prerequisites

You have synchronized IAM users. (To synchronize IAM users, on the **Dashboard** tab page, click **Synchronize** next to **IAM User Sync**.)

Procedure

Step 1 On the MRS details page, click **Nodes**.

Step 2 Unfold the node group information and select the check box of the target host.

Step 3 Choose **Node Operation** > **Isolate Host**.

Step 4 Confirm the information about the host to be isolated and click **OK**.

When **Operation successful** is displayed, click **Finish**. The host is isolated successfully, and the value of **Operating Status** becomes **Isolated**.

NOTE

For isolated hosts, you can cancel the isolation and add them to the cluster again. For details, see **Canceling Host Isolation**.

----End

5.5.6 Canceling Host Isolation

Scenario

After the exception or fault of a host is handled, you must cancel the isolation of the host for proper usage.

You can cancel the isolation of a host on MRS.

Prerequisites

- The host is in the **Isolated** state.
- The exception or fault of the host has been rectified.
- You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the MRS details page, click **Nodes**.

Step 2 Unfold the node group information and select the check box of the target host that you want to cancel its isolation.

Step 3 Choose **Node Operation** > **Cancel Host Isolation**.

Step 4 Confirm the information about the host for which the isolation is to be cancelled and click **OK**.

When **Operation successful** is displayed, click **Finish**. The host is de-isolated successfully, and the value of **Operating Status** becomes **Normal**.

----End

5.6 Job Management

5.6.1 Introduction to MRS Jobs

An MRS job is the program execution platform of MRS. It is used to process and analyze user data. After a job is created, all job information is displayed on the **Jobs** tab page. You can view a list of all jobs and create and manage jobs. If the **Jobs** tab is not displayed on the cluster details page, submit a job in the background.

Data sources processed by MRS are from OBS or HDFS. OBS is an object-based storage service that provides you with massive, secure, reliable, and cost-effective data storage capabilities. MRS can process data in OBS directly. You can view, manage, and use data by using the web page of the management control platform or OBS client. In addition, you can use REST APIs independently or integrate APIs to service applications to manage and access data.

Before creating jobs, upload the local data to OBS for MRS to compute and analyze. MRS allows exporting data from OBS to HDFS for computing and analyzing. After the analyzing and computing are complete, you can store the data in HDFS or export them to OBS. HDFS and OBS can also store the compressed data in the format of **bz2** or **gz**.

Category

An MRS cluster allows creating and managing the following jobs: If a cluster in the **Running** state fails to create a job, check the health status of related components on the cluster management page. For details, see **Viewing and Customizing Cluster Monitoring Metrics**.

- MapReduce can quickly process large-scale data in parallel. It is a distributed data processing model and execution environment. MRS supports the submission of MapReduce JAR programs.
- Spark is a distributed in-memory computing framework. MRS supports SparkSubmit, Spark Script, and Spark SQL jobs.
  - SparkSubmit: You can submit the Spark JAR and Spark Python programs, execute the Spark Application, and compute and process user data.
  - SparkScript: You can submit the SparkScript scripts and batch execute Spark SQL statements.

  - Spark SQL: You can use Spark SQL statements (similar to SQL statements) to query and analyze user data in real time.
- Hive is an open-source data warehouse based on Hadoop. MRS allows you to submit HiveScript scripts and execute Hive SQL statements.
- Flink is a distributed big data processing engine that can perform stateful computations over both unbounded and bounded data streams.
- HadoopStreaming runs mapper or reducer jobs.

Job List

Tasks are listed in chronological order by default in the task list, with the most recent jobs displayed at the top. **Table 5-23** describes the parameters in the job list.

Table 5-23 Job list parameters

Parameter	Description
Name/ID	Job name, which is set when a job is created. ID is the unique identifier of a job. After a job is added, the system automatically assigns a value to ID.
Username	Name of the user who submits a job.
Type	The following data types are supported: • DistCp: importing and exporting data • MapReduce • Spark • SparkSubmit • SparkScript • Spark SQL • Hive SQL • HiveScript • Flink • Flink SQL • HadoopStreaming **NOTE** • After importing and exporting files on the **Files** tab page, you can view the DistCp job on the **Jobs** tab page. • Spark, Hive, and Flink jobs can be added only when the Spark, Hive, and Flink components are selected during cluster creation and the cluster is running.

Parameter	Description
Status	Job status. • Submitted • Accepted • Running • Completed • Terminated • Abnormal
Result	Execution result of a job. • Undefined: indicates that the job is being executed. • **Successful**: indicates that the job has been successfully executed. • **Killed**: indicates that the job is manually terminated during execution. • **Failed**: indicates that the job fails to be executed. **NOTE** Once a job has succeeded or failed, you cannot execute it again. However, you can add a job, and set job parameters to submit a job again.
Queue Name	Name of the queue bound to the user who submits the job
Submitted	Time when a job is submitted.
Ended	Time when a job is completed or manually stopped.

Parameter	Description
Operation	Operations can be performed on the job. Click **More** for more operations in the drop-down list. • Viewing Log: Click **View Log** to view the real-time logs of running jobs. For details, see **Viewing Job Configuration and Logs**. • View Details: Click **View Details** to view the detailed configuration information about jobs. For details, see **Viewing Job Configuration and Logs**. • Stop: You can click **Stop** to stop a running job. For details, see **Stopping a Job**. • View Result: Click **View Result** to view the execution results of SparkSQL and SparkScript jobs whose status is **Completed** and result is **Successful**. • **Delete**: Delete the job. For details, see **Deleting a Job**. **NOTE** • A deleted job cannot be restored. • If you choose to save job logs to OBS or HDFS, the system compresses and saves the logs to the corresponding path after the job execution is completed. Therefore, after a job execution of this type is completed, the job status is still **Running**. After the log is successfully stored, the job status changes to **Completed**. The log storage duration depends on the log size and takes several minutes.

Table 5-24 Icon description

Icon	Description
	Select a time range for job submission to filter jobs submitted in the time range.
	Select a certain job execution result from the drop-down list to display jobs of the status. • All statuses: Filter all jobs. • Successful: Filter jobs that are successfully executed. • Undefined: Filter jobs that are being executed. • Killed: Filter jobs that are manually stopped. • Failed: Filter jobs that fail to be executed.

Icon	Description
	Select a certain job type from the drop-down list to display jobs of the type. • All types • MapReduce • HiveScript • Distcp • SparkScript • Spark SQL • Hive SQL • SparkSubmit • Flink • Flink SQL • HadoopStreaming
	In the search box, search for a job by setting the corresponding search condition and click  . • Job name. • Job ID. • Username. • Queue name.
	Click  to manually refresh the job list.

Job Execution Permission Description

For a security cluster with Kerberos authentication enabled, a user needs to synchronize an IAM user before submitting a job on the MRS web UI. After the synchronization is completed, the MRS system generates a user with the same IAM username. Whether a user has the permission to submit jobs depends on the IAM policy bound to the user during IAM synchronization. For details about the job submission policy, see **Table 2-3** in **Synchronizing IAM Users to MRS**.

When a user submits a job that involves the resource usage of a specific component, such as accessing HDFS directories and Hive tables, user **admin** (Manager administrator) must grant the relevant permission to the user. Detailed operations are as follows:

Step 1 Log in to Manager as user **admin**.

Step 2 Add the role of the component whose permission is required by the user. For details, see **Managing Roles**.

Step 3 Change the user group to which the user who submits the job belongs and add the new component role to the user group. For details, see **Creating a User**.

NOTE

After the component role bound to the user group to which the user belongs is modified, it takes some time for the role permissions to take effect.

----End

5.6.2 Running a MapReduce Job

You can submit programs developed by yourself to MRS to execute them, and obtain the results. This section describes how to submit a MapReduce job on the MRS management console. MapReduce jobs are used to submit JAR programs to quickly process massive amounts of data in parallel and create a distributed data processing and execution environment.

If the job and file management functions are not supported on the cluster details page, submit the jobs in the background.

Prerequisites

You have uploaded the program packages and data files required for running jobs to OBS or HDFS.

Before you upload the program packages and data files to OBS, you need to create an OBS agency and bind it to the MRS cluster. For details, see **Configuring a Storage-Compute Decoupled Cluster (Agency)**.

Submitting a Job on the GUI

Step 1 Log in to the MRS console.

Step 2 Choose **Clusters > Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.

Step 3 If Kerberos authentication is enabled for the cluster, perform the following steps. If Kerberos authentication is not enabled for the cluster, skip this step.

In the **Basic Information** area on the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.

NOTE

- When the policy of the user group to which the IAM user belongs changes from MRS ReadOnlyAccess to MRS CommonOperations, MRS FullAccess, or MRS Administrator, wait for 5 minutes until the new policy takes effect after the synchronization is complete because the **SSSD** (System Security Services Daemon) cache of cluster nodes needs time to be updated. Then, submit a job. Otherwise, the job may fail to be submitted.
- When the policy of the user group to which the IAM user belongs changes from MRS CommonOperations, MRS FullAccess, or MRS Administrator to MRS ReadOnlyAccess, wait for 5 minutes until the new policy takes effect after the synchronization is complete because the **SSSD** cache of cluster nodes needs time to be updated.

Step 4 Click the **Jobs** tab.

Step 5 Click **Create**. The **Create Job** page is displayed.

NOTE

If the IAM username contains spaces (for example, **admin 01**), a job cannot be created.

Step 6 In **Type**, select **MapReduce**. Configure other job information.

Table 5-25 Job configuration information

Parameter	Description
Name	Job name. It contains 1 to 64 characters. Only letters, digits, hyphens (-), and underscores (_) are allowed. **NOTE** You are advised to set different names for different jobs.
Program Path	Path of the program package to be executed. The following requirements must be met: • Contains a maximum of 1,023 characters, excluding special characters such as ;|&><'$. The parameter value cannot be empty or full of spaces. • The path of the program to be executed can be stored in HDFS or OBS. The path varies depending on the file system. – OBS: The path must start with **obs://**. Example: **obs://wordcount/program/*xxx*.jar** – HDFS: The path must start with **/user**. For details about how to import data to HDFS, see **Importing Data**. • For SparkScript and HiveScript, the path must end with **.sql**. For MapReduce, the path must end with **.jar**. For Flink and SparkSubmit, the path must end with **.jar** or **.py**. The **.sql**, **.jar**, and **.py** are case-insensitive.
Parameters	(Optional) It is the key parameter for program execution. Multiple parameters are separated by space. Configuration method: *Program class name Data input path Data output path* • Program class name: It is specified by a function in your program. MRS is responsible for transferring parameters only. • Data input path: Click **HDFS** or **OBS** to select a path or manually enter a correct path. • Data output path: Enter a directory that does not exist. The parameter contains a maximum of 150,000 characters. It cannot contain special characters ;|&><'$, but can be left blank. **CAUTION** If you enter a parameter with sensitive information (such as the login password), the parameter may be exposed in the job details display and log printing. Exercise caution when performing this operation.

Parameter	Description
Service Parameter	(Optional) It is used to modify service parameters for the job. The parameter modification applies only to the current job. To make the modification take effect permanently for the cluster, follow instructions in **Configuring Service Parameters**. To add multiple parameters, click ⊕ on the right. To delete a parameter, click **Delete** on the right. **Table 5-26** lists the common service configuration parameters.
Command Reference	Command submitted to the background for execution when a job is submitted.

Table 5-26 Service Parameter parameters

Parameter	Description	Example Value
fs.obs.access.key	Key ID for accessing OBS.	-
fs.obs.secret.key	Key corresponding to the key ID for accessing OBS.	-

Step 7 Confirm job configuration information and click **OK**.

After the job is created, you can manage it.

----End

Submitting a Job in the Background

The default client installation path is /opt/Bigdata/client. Configure the path based on site requirements.

Step 1 Log in to the MRS console.

Step 2 Choose **Clusters > Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.

Step 3 On the **Nodes** tab page, click the name of a Master node to go to the ECS management console.

Step 4 Click **Remote Login** in the upper right corner of the page.

Step 5 Enter the username and password of the Master node as prompted. The username is **root** and the password is the one set during cluster creation.

Step 6 Run the following command to initialize environment variables:

source /opt/Bigdata/client/bigdata_env

Step 7 If the Kerberos authentication is enabled for the current cluster, run the following command to authenticate the user. If the Kerberos authentication is disabled for the current cluster, skip this step.

kinit *MRS cluster user*

Example: **kinit admin**

Step 8 Run the following command to copy the program in the OBS file system to the Master node in the cluster:

hadoop fs -Dfs.obs.access.key=AK -Dfs.obs.secret.key=SK -copyToLocal source_path.jar target_path.jar

Example: **hadoop fs -Dfs.obs.access.key=XXXX -Dfs.obs.secret.key=XXXX -copyToLocal "obs://mrs-word/program/hadoop-mapreduce-examples-XXX.jar" "/home/omm/hadoop-mapreduce-examples-XXX.jar"**

NOTE

- Commands carrying authentication passwords pose security risks. Disable historical command recording before running such commands to prevent information leakage.
- You can log in to the OBS Console using AK/SK. To obtain AK/SK information, click the username in the upper right corner of the management console and choose **My Credentials** > **Access Keys**.

Step 9 Run the following command to submit a wordcount job. If data needs to be read from OBS or outputted to OBS, the AK/SK parameters need to be added.

source /opt/Bigdata/client/bigdata_env;hadoop jar execute_jar wordcount input_path output_path

Example: **source /opt/Bigdata/client/bigdata_env;hadoop jar /home/omm/hadoop-mapreduce-examples-XXX.jar wordcount -Dfs.obs.access.key=XXXX -Dfs.obs.secret.key=XXXX "obs://mrs-word/input/*" "obs://mrs-word/output/"**

In the preceding command, **input_path** indicates a path for storing job input files on OBS. **output_path** indicates a path for storing job output files on OBS and needs to be set to a directory that does not exist

----End

5.6.3 Running a SparkSubmit Job

You can submit programs developed by yourself to MRS to execute them, and obtain the results. This section describes how to submit a Spark job on the MRS console.

Prerequisites

You have uploaded the program packages and data files required for running jobs to OBS or HDFS.

NOTE

- The example JAR file provided by the system is *{Client installation directory}***/Spark2x/spark/examples/jars/spark-examples_*.jar**.
- Log in to the client node and run the following command to upload the JAR package to HDFS (for example, **/tmp**):

  hdfs dfs -put *{Client installation directory}***/Spark2x/spark/examples/jars/spark-examples_*.jar /tmp**

Submitting a Job on the GUI

Step 1 Log in to the MRS console.

Step 2 Choose **Clusters > Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.

Step 3 If Kerberos authentication is enabled for the cluster, perform the following steps. If Kerberos authentication is not enabled for the cluster, skip this step.

In the **Basic Information** area on the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.

NOTE

- When the policy of the user group to which the IAM user belongs changes from MRS ReadOnlyAccess to MRS CommonOperations, MRS FullAccess, or MRS Administrator, wait for 5 minutes until the new policy takes effect after the synchronization is complete because the **SSSD** (System Security Services Daemon) cache of cluster nodes needs time to be updated. Then, submit a job. Otherwise, the job may fail to be submitted.
- When the policy of the user group to which the IAM user belongs changes from MRS CommonOperations, MRS FullAccess, or MRS Administrator to MRS ReadOnlyAccess, wait for 5 minutes until the new policy takes effect after the synchronization is complete because the **SSSD** cache of cluster nodes needs time to be updated.

Step 4 Click the **Jobs** tab.

Step 5 Click **Create**. The **Create Job** page is displayed.

Step 6 Configure job information. Set to **SparkSubmit** and configure other parameters of the SparkSubmit job by referring to **Table 5-27**

Table 5-27 Job configuration information

Parameter	Description
Name	Job name. It contains 1 to 64 characters. Only letters, digits, hyphens (-), and underscores (_) are allowed. **NOTE** You are advised to set different names for different jobs.

Parameter	Description
Program Path	Path of the program package to be executed. The following requirements must be met: • Contains a maximum of 1,023 characters, excluding special characters such as ;|&><'$. The parameter value cannot be empty or full of spaces. • The path of the program to be executed can be stored in HDFS or OBS. The path varies depending on the file system. – OBS: The path must start with **obs://**. Example: **obs://wordcount/program/*xxx*.jar** – HDFS: The path must start with **/user**. For details about how to import data to HDFS, see **Importing Data**. • For SparkScript and HiveScript, the path must end with **.sql**. For MapReduce, the path must end with **.jar**. For Flink and SparkSubmit, the path must end with **.jar** or **.py**. The **.sql**, **.jar**, and **.py** are case-insensitive.
Program Parameter	(Optional) Used to configure optimization parameters such as threads, memory, and vCPUs for the job to optimize resource usage and improve job execution performance. **Table 5-28** describes the common parameters of a running program.
Parameters	(Optional) Key parameter for program execution. The parameter is specified by the function of the user's program. MRS is only responsible for loading the parameter. Multiple parameters are separated by space. The parameter contains a maximum of 150,000 characters. It cannot contain special characters ;|&><'$, but can be left blank. **CAUTION** If you enter a parameter with sensitive information (such as the login password), the parameter may be exposed in the job details display and log printing. Exercise caution when performing this operation.
Service Parameter	(Optional) It is used to modify service parameters for the job. The parameter modification applies only to the current job. To make the modification take effect permanently for the cluster, follow instructions in **Configuring Service Parameters**. To add multiple parameters, click ⊕ on the right. To delete a parameter, click **Delete** on the right. **Table 5-29** lists the common service configuration parameters. **NOTE** If you need to run a long-term job, such as SparkStreaming, and access OBS, you need to use **Service Parameter** to import the AK/SK for accessing OBS.
Command Reference	Command submitted to the background for execution when a job is submitted.

Table 5-28 Program parameters

Parameter	Description	Example Value
--conf	Add the task configuration items.	spark.executor.memory=2G
--driver-memory	Set the running memory of driver.	2G
--num-executors	Set the number of executors to be started.	5
--executor-cores	Set the number of executor cores.	2
--class	Set the main class of a task.	org.apache.spark.examples.SparkPi
--files	Upload files to a task. The files can be custom configuration files or some data files from OBS or HDFS.	-
--jars	Upload additional dependency packages of a task to add the external dependency packages to the task.	-
--executor-memory	Set executor memory.	2G
--conf spark-yarn.maxAppAttempts	Control the number of AM retries.	If this parameter is set to **0**, retry is not allowed. If this parameter is set to **1**, one retry is allowed.

Table 5-29 Service Parameter parameters

Parameter	Description	Example Value
fs.obs.access.key	Key ID for accessing OBS.	-
fs.obs.secret.key	Key corresponding to the key ID for accessing OBS.	-

Step 7 Confirm job configuration information and click **OK**.

After the job is created, you can manage it.

----End

Submitting a Job in the Background

The default client installation path is /opt/Bigdata/client. Configure the path based on site requirements.

Step 1 Create a user for submitting jobs. For details, see **Creating a User**.

In this example, a machine-machine user has been created, and user groups (**hadoop** and **supergroup**), the primary group (**supergroup**), and role permissions (**System_administrator** and **default**) have been correctly assigned to the user.

Step 2 Download the authentication credential.

Log in to FusionInsight Manager and choose **System** > **Permission** > **User**. In the **Operation** column of the newly created user, choose **More** > **Download Authentication Credential**.

Step 3 Upload JAR files related to the job to the cluster. In this example, the sample JAR file built in Spark is used. It is stored in **$SPARK_HOME/examples/jars**.

Step 4 Upload the authentication credential of the user created in **Step 2** to the **/opt** directory of the cluster and run the following command to decompress the credential:

tar –xvf MRSTest _*xxxxxx*_keytab.tar

You will obtain two files: **user.keytab** and **krb5.conf**.

Step 5 Before performing operations on the cluster, run the following commands:

source /opt/Bigdata/client/bigdata_env

cd $SPARK_HOME

Step 6 Run the following command to submit the Spark job:

./bin/spark-submit --master yarn --deploy-mode client --conf spark.yarn.principal=MRSTest --conf spark.yarn.keytab=/opt/user.keytab --class org.apache.spark.examples.SparkPi examples/jars/spark-examples_*.jar 10

Parameter description:

1. Computing capability of Yarn, which specifies that the job is submitted in client mode.
2. Configuration item of the Spark job. The authentication file and username are transferred here.
3. **spark.yarn.principal**: user created in step 1
4. **spark.yarn.keytab**: keytab file used for authentication
5. *xx*.**jar**: JAR file used by the job

----End

5.6.4 Running a HiveSQL Job

You can submit programs developed by yourself to MRS to execute them, and obtain the results. This section describes how to submit a HiveSQL job on the MRS management console. HiveSQL jobs are used to submit SQL statements and script files for data query and analysis. Both SQL statements and scripts are supported. If SQL statements contain sensitive information, use Script to submit them.

Prerequisites

You have uploaded the program packages and data files required for running jobs to OBS or HDFS.

Submitting a Job on the GUI

Step 1 Log in to the MRS console.

Step 2 Choose **Clusters** > **Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.

Step 3 If Kerberos authentication is enabled for the cluster, perform the following steps. If Kerberos authentication is not enabled for the cluster, skip this step.

In the **Basic Information** area on the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.

NOTE

- When the policy of the user group to which the IAM user belongs changes from MRS ReadOnlyAccess to MRS CommonOperations, MRS FullAccess, or MRS Administrator, wait for 5 minutes until the new policy takes effect after the synchronization is complete because the **SSSD** (System Security Services Daemon) cache of cluster nodes needs time to be updated. Then, submit a job. Otherwise, the job may fail to be submitted.
- When the policy of the user group to which the IAM user belongs changes from MRS CommonOperations, MRS FullAccess, or MRS Administrator to MRS ReadOnlyAccess, wait for 5 minutes until the new policy takes effect after the synchronization is complete because the **SSSD** cache of cluster nodes needs time to be updated.

Step 4 Click the **Jobs** tab.

Step 5 Click **Create**. The **Create Job** page is displayed.

Step 6 Configure job information. Set **Type** to **HiveSql** and configure HiveSQL job information be referring to **Table 5-30**.

Table 5-30 Job configuration information

Parameter	Description
Name	Job name. It contains 1 to 64 characters. Only letters, digits, hyphens (-), and underscores (_) are allowed. **NOTE** You are advised to set different names for different jobs.
SQL Type	Submission type of the SQL statement • SQL • Script
SQL Statement	This parameter is valid only when **SQL Type** is set to **SQL**. Enter the SQL statement to be executed, and then click **Check** to check whether the SQL statement is correct. If you want to submit and execute multiple statements at the same time, use semicolons (;) to separate them.

Parameter	Description
SQL File	This parameter is valid only when **SQL Type** is set to **Script**. The path of the SQL file to be executed must meet the following requirements: • Contains a maximum of 1,023 characters, excluding special characters such as ;|&><'$. The parameter value cannot be empty or full of spaces. • The path of the program to be executed can be stored in HDFS or OBS. The path varies depending on the file system. – OBS: The path must start with **obs://**. Example: **obs://wordcount/program/*xxx*.jar** – HDFS: The path must start with **/user**. For details about how to import data to HDFS, see **Importing Data**. • For SparkScript and HiveScript, the path must end with **.sql**. For MapReduce, the path must end with **.jar**. For Flink and SparkSubmit, the path must end with **.jar** or **.py**. The **.sql**, **.jar**, and **.py** are case-insensitive. **NOTE** A file path on OBS can start with **obs://**. To submit jobs in this format, you need to configure permissions for accessing OBS. • If the OBS permission control function is enabled during cluster creation, you can use the **obs://** directory without extra configuration. • If the OBS permission control function is not enabled or is not supported when you create a cluster, configure the function by following instructions in **Accessing OBS**.
Program Parameter	(Optional) Used to configure optimization parameters such as threads, memory, and vCPUs for the job to optimize resource usage and improve job execution performance. **Table 5-31** describes the common parameters of a running program.
Service Parameter	(Optional) It is used to modify service parameters for the job. The parameter modification applies only to the current job. To make the modification take effect permanently for the cluster, follow instructions in **Configuring Service Parameters**. To add multiple parameters, click ⊕ on the right. To delete a parameter, click **Delete** on the right. **Table 5-32** lists the common service configuration parameters.
Command Reference	Command submitted to the background for execution when a job is submitted.

Table 5-31 Program parameters

Parameter	Description	Example Value
--hiveconf	Hive service configuration, for example, set the execution engine to MapReduce.	Setting the execution engine to MR: **--hiveconf "hive.execution.engine=mr"**
--hivevar	Custom variable, for example, variable ID.	Setting the variable ID: **--hivevar id="123" select * from test where id = ${hivevar:id}**

Table 5-32 Service parameters

Parameter	Description	Example Value
fs.obs.access.key	Key ID for accessing OBS.	-
fs.obs.secret.key	Key corresponding to the key ID for accessing OBS.	-
hive.execution.engine	Engine for running a job.	• mr • tez

Step 7 Confirm job configuration information and click **OK**.

After the job is created, you can manage it.

----End

Submitting a Job in the Background

Step 1 Log in to the MRS console.

Step 2 Choose **Clusters** > **Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.

Step 3 On the **Nodes** tab page, click the name of a Master node to go to the ECS management console.

Step 4 Click **Remote Login** in the upper right corner of the page.

Step 5 Enter the username and password of the Master node as prompted. The username is **root** and the password is the one set during cluster creation.

Step 6 Run the following command to initialize environment variables:

source /opt/BigData/client/bigdata_env

NOTE

- The default client installation path is /opt/Bigdata/client. Configure the path based on site requirements.

Step 7 If the Kerberos authentication is enabled for the current cluster, run the following command to authenticate the user. If the Kerberos authentication is disabled for the current cluster, that is, the cluster is in normal mode, skip this step.

kinit *MRS cluster user* (The user must be in the **hive** user group.)

Step 8 Run the **beeline** command to connect to HiveServer and run tasks.

beeline

For clusters in normal mode, run the following commands. If no component service user is specified, the current OS user is used to log in to the HiveServer.

beeline -n *Component service user*

beeline -f *SQL files* (SQLs in the execution files)

----End

5.6.5 Running a SparkSql Job

You can submit programs developed by yourself to MRS to execute them, and obtain the results. This section describes how to submit a SparkSQL job on the MRS console. SparkSQL jobs are used for data query and analysis. Both SQL statements and scripts are supported. If SQL statements contain sensitive information, use Spark Script to submit them.

Prerequisites

You have uploaded the program packages and data files required for running jobs to OBS or HDFS.

Submitting a Job on the GUI

Step 1 Log in to the MRS console.

Step 2 Choose **Clusters > Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.

Step 3 If Kerberos authentication is enabled for the cluster, perform the following steps. If Kerberos authentication is not enabled for the cluster, skip this step.

In the **Basic Information** area on the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.

NOTE

- When the policy of the user group to which the IAM user belongs changes from MRS ReadOnlyAccess to MRS CommonOperations, MRS FullAccess, or MRS Administrator, wait for 5 minutes until the new policy takes effect after the synchronization is complete because the **SSSD** (System Security Services Daemon) cache of cluster nodes needs time to be updated. Then, submit a job. Otherwise, the job may fail to be submitted.
- When the policy of the user group to which the IAM user belongs changes from MRS CommonOperations, MRS FullAccess, or MRS Administrator to MRS ReadOnlyAccess, wait for 5 minutes until the new policy takes effect after the synchronization is complete because the **SSSD** cache of cluster nodes needs time to be updated.

Step 4 Click the **Jobs** tab.

Step 5 Click **Create**. On the displayed **Create Job** page, set **Type** to **SparkSql** and configure SparkSql job information by referring to **Table 5-33**.

Table 5-33 Job configuration information

Parameter	Description
Name	Job name. It contains 1 to 64 characters. Only letters, digits, hyphens (-), and underscores (_) are allowed. **NOTE** You are advised to set different names for different jobs.
SQL Type	Submission type of the SQL statement • SQL • Script
SQL Statement	This parameter is valid only when **SQL Type** is set to **SQL**. Enter the SQL statement to be executed, and then click **Check** to check whether the SQL statement is correct. If you want to submit and execute multiple statements at the same time, use semicolons (;) to separate them.

Parameter	Description
SQL File	This parameter is valid only when **SQL Type** is set to **Script**. The path of the SQL file to be executed must meet the following requirements: • Contains a maximum of 1,023 characters, excluding special characters such as ;|&><'$. The parameter value cannot be empty or full of spaces. • The path of the program to be executed can be stored in HDFS or OBS. The path varies depending on the file system. – OBS: The path must start with **obs://**. Example: **obs://wordcount/program/*xxx*.jar** – HDFS: The path must start with **/user**. For details about how to import data to HDFS, see **Importing Data**. • For SparkScript and HiveScript, the path must end with **.sql**. For MapReduce, the path must end with **.jar**. For Flink and SparkSubmit, the path must end with **.jar** or **.py**. The **.sql**, **.jar**, and **.py** are case-insensitive. **NOTE** A file path on OBS can start with **obs://**. To submit jobs in this format, you need to configure permissions for accessing OBS. • If the OBS permission control function is enabled during cluster creation, you can use the **obs://** directory without extra configuration. • If the OBS permission control function is not enabled or is not supported when you create a cluster, configure the function by following instructions in **Accessing OBS**.
Program Parameter	(Optional) Used to configure optimization parameters such as threads, memory, and vCPUs for the job to optimize resource usage and improve job execution performance. **Table 5-34** describes the common parameters of a running program.
Service Parameter	(Optional) It is used to modify service parameters for the job. The parameter modification applies only to the current job. To make the modification take effect permanently for the cluster, follow instructions in **Configuring Service Parameters**. To add multiple parameters, click ⊕ on the right. To delete a parameter, click **Delete** on the right. **Table 5-35** lists the common service configuration parameters.
Command Reference	Command submitted to the background for execution when a job is submitted.

Table 5-34 Program parameters

Parameter	Description	Example Value
--conf	Task configuration items to be added.	spark.executor.memory=2G
--driver-memory	Running memory of a driver.	2G
--num-executors	Number of executors to be started.	5
--executor-cores	Number of executor cores.	2
--jars	Additional dependency packages of a task, which is used to add the external dependency packages to the task.	-
--executor-memory	Executor memory.	2G

Table 5-35 Service parameters

Parameter	Description	Example Value
fs.obs.access.key	Key ID for accessing OBS.	-
fs.obs.secret.key	Key corresponding to the key ID for accessing OBS.	-

Step 6 Confirm job configuration information and click **OK**.

After the job is created, you can manage it.

----End

Submitting a Job in the Background

The default client installation path is /opt/Bigdata/client. Configure the path based on site requirements.

Step 1 Create a user for submitting jobs. For details, see **Creating a User**.

In this example, a machine-machine user has been created, and user groups (**hadoop** and **supergroup**), the primary group (**supergroup**), and role permissions (**System_administrator** and **default**) have been correctly assigned to the user.

Step 2 Download the authentication credential.

Log in to FusionInsight Manager and choose **System** > **Permission** > **User**. In the **Operation** column of the newly created user, choose **More** > **Download Authentication Credential**.

Step 3 Log in to the node where the Spark client is located, upload the user authentication credential created in **2** to the **/opt** directory of the cluster, and run the following command to decompress the package:

tar –xvf MRSTest *_xxxxxx_***keytab.tar**

After the decompression, you obtain the **user.keytab** and **krb5.conf** files.

Step 4 Before performing operations on the cluster, run the following commands:

source /opt/Bigdata/client/bigdata_env

cd $SPARK_HOME

Step 5 Open the **spark-sql** CLI and run the following SQL statement:

./bin/spark-sql --conf spark.yarn.principal=MRSTest --conf spark.yarn.keytab=/opt/user.keytab

To execute the SQL file, you need to upload the SQL file (for example, to the **/opt/** directory). After the file is uploaded, run the following command:

./bin/spark-sql --conf spark.yarn.principal=MRSTest --conf spark.yarn.keytab=/opt/user.keytab -f /opt/script.sql

----End

5.6.6 Running a Flink Job

You can submit programs developed by yourself to MRS to execute them, and obtain the results. This section describes how to submit a Flink job on the MRS management console. Flink jobs are used to submit JAR programs to process streaming data.

Prerequisites

You have uploaded the program packages and data files required for running jobs to OBS or HDFS.

Submitting a Job on the GUI

Step 1 Log in to the MRS console.

Step 2 Choose **Clusters > Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.

Step 3 If Kerberos authentication is enabled for the cluster, perform the following steps. If Kerberos authentication is not enabled for the cluster, skip this step.

In the **Basic Information** area on the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.

NOTE

- When the policy of the user group to which the IAM user belongs changes from MRS ReadOnlyAccess to MRS CommonOperations, MRS FullAccess, or MRS Administrator, wait for 5 minutes until the new policy takes effect after the synchronization is complete because the **SSSD** (System Security Services Daemon) cache of cluster nodes needs time to be updated. Then, submit a job. Otherwise, the job may fail to be submitted.
- When the policy of the user group to which the IAM user belongs changes from MRS CommonOperations, MRS FullAccess, or MRS Administrator to MRS ReadOnlyAccess, wait for 5 minutes until the new policy takes effect after the synchronization is complete because the **SSSD** cache of cluster nodes needs time to be updated.

Step 4 Click the **Jobs** tab.

Step 5 Click **Create**. The **Create Job** page is displayed.

Step 6 Set **Type** to **Flink**. Configure Flink job information by referring to **Table 5-36**.

Table 5-36 Job configuration information

Parameter	Description
Name	Job name. It contains 1 to 64 characters. Only letters, digits, hyphens (-), and underscores (_) are allowed. **NOTE** You are advised to set different names for different jobs.
Program Path	Path of the program package to be executed. The following requirements must be met: • Contains a maximum of 1,023 characters, excluding special characters such as ;|&><'$. The parameter value cannot be empty or full of spaces. • The path of the program to be executed can be stored in HDFS or OBS. The path varies depending on the file system. – OBS: The path must start with **obs://**. Example: **obs://wordcount/program/*xxx*.jar** – HDFS: The path must start with **/user**. For details about how to import data to HDFS, see **Importing Data**.
Program Parameter	(Optional) Used to configure optimization parameters such as threads, memory, and vCPUs for the job to optimize resource usage and improve job execution performance. **Table 5-37** describes the common parameters of a running program.

Parameter	Description
Parameters	(Optional) Key parameter for program execution. The parameter is specified by the function of the user's program. MRS is only responsible for loading the parameter. Multiple parameters are separated by space. The parameter contains a maximum of 150,000 characters. It cannot contain special characters ;|&><'$, but can be left blank. **CAUTION** If you enter a parameter with sensitive information (such as the login password), the parameter may be exposed in the job details display and log printing. Exercise caution when performing this operation.
Service Parameter	(Optional) It is used to modify service parameters for the job. The parameter modification applies only to the current job. To make the modification take effect permanently for the cluster, follow instructions in **Configuring Service Parameters**. To add multiple parameters, click ⊕ on the right. To delete a parameter, click **Delete** on the right. **Table 5-38** describes the common parameters of a service.
Command Reference	Command submitted to the background for execution when a job is submitted.

Table 5-37 Program parameters

Parameter	Description	Example Value
-ytm	Memory size of each TaskManager container. (Optional unit. The unit is MB by default.)	1024
-yjm	Memory size of JobManager container. (Optional unit. The unit is MB by default.)	1024
-yn	Number of Yarn containers allocated to applications. The value is the same as the number of TaskManagers.	2
-ys	Number of TaskManager cores.	2
-ynm	Custom name of an application on Yarn.	test
-c	Class of the program entry point (for example, the **main** or **getPlan()** method). This parameter is required only when the JAR file does not specify the class of its manifest.	com.bigdata.mrs.test

NOTE

The **-yn** parameter is not supported.

Table 5-38 Service parameters

Parameter	Description	Example Value
fs.obs.access.key	Key ID for accessing OBS.	-
fs.obs.secret.key	Key corresponding to the key ID for accessing OBS.	-

Step 7 Confirm job configuration information and click **OK**.

After the job is created, you can manage it.

----End

Submitting a Job in the Background

The default client installation path is /opt/Bigdata/client. Configure the path based on site requirements.

Step 1 Log in to the MRS client.

Step 2 Run the following command to initialize environment variables:

source /opt/Bigdata/client/bigdata_env

Step 3 If Kerberos authentication is enabled for the cluster, perform the following steps. If Kerberos authentication is not enabled for the cluster, skip this step.

1. Prepare a user for submitting Flink jobs.
2. Log in to Manager as the newly created user.

   Log in to Manager of the cluster. Choose **System** > **Manage User**. In the **Operation** column of the row that contains the added user, choose **More** > **Download authentication credential** to locate the row that contains the user.
3. Decompress the downloaded authentication credential package and copy the obtained file to a directory on the client node, for example, **/opt/Bigdata/client/Flink/flink/conf**. If the client is installed on a node outside the cluster, copy the obtained file to the **/etc/** directory on this node.
4. In security mode, add the service IP address of the node where the client is installed and floating IP address of Manager to the **jobmanager.web.allow-access-address** configuration item in the **/opt/Bigdata/client/Flink/flink/conf/flink-conf.yaml** file.
5. Run the following commands to configure security authentication by adding the **keytab** path and username to the **/opt/Bigdata/client/Flink/flink/conf/flink-conf.yaml** configuration file.

   security.kerberos.login.keytab: *<user.keytab file path>*
   security.kerberos.login.principal: *<Username>*

   Example:

```
security.kerberos.login.keytab: /opt/Bigdata/client/Flink/flink/conf/user.keytab
security.kerberos.login.principal: test
```

6. In the **bin** directory of the Flink client, run the following command to perform security hardening. Then, set a password for submitting jobs.

   sh generate_keystore.sh

   This script automatically replaces the SSL value in the **/opt/Bigdata/client/Flink/flink/conf/flink-conf.yaml** file.

   Table 5-39 Parameter description

Parameter	Example Value	Description
security.ssl.rest.enabled	true	Switch to enable external SSL.
security.ssl.rest.keystore	${path}/flink.keystore	Path for storing **keystore**.
security.ssl.rest.keystore-password	123456	Password of the **keystore**. **123456** indicates a user-defined password is required.
security.ssl.rest.key-password	123456	Password of the SSL key. **123456** indicates a user-defined password is required.
security.ssl.rest.truststore	${path}/flink.truststore	Path for storing the **truststore**.
security.ssl.rest.truststore-password	123456	Password of the **truststore**. **123456** indicates a user-defined password is required.

   NOTE

   - The generated **flink.keystore**, **flink.truststore**, and **security.cookie** items are automatically filled in the corresponding configuration items in **flink-conf.yaml**.
   - You can obtain the values of **security.ssl.key-password**, **security.ssl.keystore-password**, and **security.ssl.truststore-password** using the Manager plaintext encryption API by running the following command:

     curl -k -i -u <*user name*>:<*password*> -X POST -HContent-type:application/json -d '{"plainText":"<*password*>"}' 'https://*x.x.x.x*:28443/web/api/v2/tools/encrypt'; In the preceding command, <*password*> must be the same as the password used for issuing the certificate, and *x.x.x.x* indicates the floating IP address of Manager in the cluster.

     Commands carrying authentication passwords pose security risks. Disable historical command recording before running such commands to prevent information leakage.

7. Configure paths for the client to access the **flink.keystore** and **flink.truststore** files.

- Absolute path: After the script is executed, the file path of **flink.keystore** and **flink.truststore** is automatically set to the absolute path **opt/Bigdata/client/Flink/flink/conf/** in the **flink-conf.yaml** file. In this case, you need to move the **flink.keystore** and **flink.truststore** files from the **conf** directory to this absolute path on the Flink client and Yarn nodes.
- Relative path: Perform the following steps to set the file path of **flink.keystore** and **flink.truststore** to the relative path and ensure that the directory where the Flink client command is executed can directly access the relative paths.
  i. In the **/opt/Bigdata/client/Flink/flink/conf/**directory, create a new directory, for example, **ssl**.
  ii. Move the **flink.keystore** and **flink.truststore** file to the /**opt/Bigdata/client/Flink/flink/conf/ssl/** directory.
  iii. Change the values of the following parameters in the **flink-conf.yaml** file to relative paths:
  ```
  security.ssl.keystore: ssl/flink.keystore
  security.ssl.truststore: ssl/flink.truststore
  ```

8. If the client is installed on a node outside the cluster, add the following configuration to the configuration file (for example, **/opt/Bigdata/client/Flink/fink/conf/flink-conf.yaml**). Replace ***xx.xx.xxx.xxx*** with the IP address of the node where the client resides.
   ```
   web.access-control-allow-origin: xx.xx.xxx.xxx
   jobmanager.web.allow-access-address: xx.xx.xxx.xxx
   ```

Step 4 Run a wordcount job.

- Normal cluster (Kerberos authentication disabled)
  - Run the following commands to start a session and submit a job in the session:
    ```
    yarn-session.sh -nm "session-name" -d
    flink run /opt/Bigdata/client/Flink/flink/examples/streaming/WordCount.jar
    ```
  - Run the following command to submit a single job on Yarn:
    ```
    flink run -m yarn-cluster /opt/Bigdata/client/Flink/flink/examples/streaming/WordCount.jar
    ```
- Security cluster (Kerberos authentication enabled)
  - If the **flink.keystore** and **flink.truststore** file are stored in the absolute path:
    - Run the following commands to start a session and submit a job in the session:
      ```
      yarn-session.sh -nm "session-name" -d
      flink run /opt/Bigdata/client/Flink/flink/examples/streaming/WordCount.jar
      ```
    - Run the following command to submit a single job on Yarn:
      ```
      flink run -m yarn-cluster /opt/Bigdata/client/Flink/flink/examples/streaming/WordCount.jar
      ```
  - If the **flink.keystore** and **flink.truststore** file are stored in the relative path:
    - In the same directory of SSL, run the following command to start a session and submit jobs in the session. The SSL directory is a relative path. For example, if the SSL directory is **opt/Bigdata/client/Flink/flink/conf/**, then run the following command in this directory:
      ```
      yarn-session.sh -t ssl/ -nm "session-name" -d
      flink run /opt/Bigdata/client/Flink/flink/examples/streaming/WordCount.jar
      ```

- Run the following command to submit a single job on Yarn:
  flink run -m yarn-cluster -yt ssl/ /opt/Bigdata/client/Flink/flink/examples/streaming/WordCount.jar

----End

5.6.7 Viewing Job Configuration and Logs

This section describes how to view job configuration and logs.

Background

- You can view configuration information of all jobs.
- You can only view logs of running jobs.

  Because logs of Spark SQL and DistCp jobs are not in the background, you cannot view logs of running Spark SQL and DistCp jobs.

Procedure

Step 1 Log in to the MRS management console.

Step 2 Choose **Clusters** > **Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.

Step 3 Click **Jobs**.

Step 4 In the **Operation** column of the job to be viewed, click **View Details**.

In the **View Details** window that is displayed, configuration of the selected job is displayed.

Step 5 Select a running job, and click **View Log** in the **Operation** column.

In the new page that is displayed, real-time log information of the job is displayed.

Each tenant can submit and view 10 jobs concurrently.

----End

5.6.8 Stopping a Job

This section describes how to stop running MRS jobs.

Background

You cannot stop Spark SQL jobs. After a job is stopped, its status changes to **Terminated** and the job cannot be executed again.

Procedure

Step 1 Log in to the MRS management console.

Step 2 Choose **Clusters** > **Active Clusters**, select a running cluster, and click its name.

The cluster details page is displayed.

Step 3 Click **Jobs**.

Step 4 Select a running job, and choose **More > Stop** in the **Operation** column.

The job status changes from **Running** to **Terminated**.

----End

5.6.9 Deleting a Job

This section describes how to delete an MRS job. After a job is executed, you can delete it if you do not need to view its information.

Background

Jobs can be deleted one after another or in a batch. A deleted job cannot be restored. Therefore, exercise caution when deleting a job.

Procedure

Step 1 Log in to the MRS management console.

Step 2 Choose **Clusters** > **Active Clusters**, select a running cluster, and click its name.

The cluster details page is displayed.

Step 3 Click **Jobs**.

Step 4 Choose **More > Delete** from the **Operation** in the row of the target job to be deleted.

In this step, you can only delete one job only.

Step 5 If you select multiple jobs and click **Delete** on the upper left of the job list.

You can delete one, multiple, or all jobs.

----End

5.6.10 Configuring Job Notification Rules

MRS uses SMN to offer a publish/subscribe model to achieve one-to-multiple message subscriptions and notifications in a variety of message types (SMSs and emails). You can configure job notification rules to receive notifications immediately upon a job execution success or failure.

Procedure

Step 1 Log in to the management console.

Step 2 Click **Service List**. Under **Management & Governance**, click **Simple Message Notification**.

Step 3 Create a topic and add subscriptions to the topic. For details, see **Configuring Message Notification**.

Step 4 Go to the MRS management console, and click the cluster name to go to the cluster details page.

Step 5 Click the **Alarms** tab, and choose **Notification Rules** > **Add Notification Rule**.

Step 6 Configure a notification rule for sending job execution results to subscribers.

Table 5-40 Parameters of adding a notification rule

Parameter	Description
Rule Name	User-defined notification rule name. Only digits, letters, hyphens (-), and underscores (_) are allowed.
Message Notification	If you enable this function, subscription messages will be sent to subscribers.
Topic Name	Select an existing topic or click **Create Topic** to create a topic.
Notification Type	Select **Event**.
Subscription Items	1. Click ⊞ next to **Suggestion**. 2. Click ⊞ next to **Manager**. 3. Select **Job Running Succeeded** and **Job Running Failed**.

----End

5.7 Component Management

5.7.1 Object Management

MRS contains different types of basic objects. **Table 5-41** describes these objects.

Table 5-41 MRS basic object overview

Object	Description	Example
Service	Function set that can complete specific business.	KrbServer service and LdapServer service
Service instance	Specific instance of a service, usually called service.	KrbServer service
Service role	Function entity that forms a complete service, usually called role.	KrbServer is composed of the KerberosAdmin role and KerberosServer role.

Object	Description	Example
Role instance	Specific instance of a service role running on a host.	KerberosAdmin that is running on Host2 and KerberosServer that is running on Host3
Host	An ECS running Linux OS.	Host1 to Host5
Rack	Physical entity that contains multiple hosts connecting to the same switch.	Rack1 contains Host1 to Host5.
Cluster	Logical entity that consists of multiple hosts and provides various services.	Cluster1 cluster consists of five hosts (Host1 to Host5) and provides services such as KrbServer and LdapServer.

5.7.2 Viewing Configuration

On MRS, you can view the configuration of services (including roles) and role instances.

Prerequisites

You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

- Query service configuration.
  a. On the cluster details page, click the **Components** tab.
  b. Select the target service from the service list.
  c. Click **Service Configuration**.
  d. Switch **Basic** to **All**. All configuration parameters of the service are displayed in the navigation tree. The service name and role names are displayed from upper to lower in the navigation tree.
  e. In the navigation tree, select a specified parameter and change its value. You can also enter the parameter name in the **Search** box to search for the parameter and view the result.

     The parameters under the service nodes and role nodes are service configuration parameters and role configuration parameters respectively.
- Query role instance configurations.
  a. On the MRS cluster details page, click **Components**.
  b. Select the target service from the service list.
  c. Click the **Instances** tab.
  d. Click the target role instance from the role instance list.
  e. Click **Instance Configuration**.
  f. Switch **Basic** to **All** on the right of the page. All configuration parameters of the role instance are displayed in the navigation tree.

g. In the navigation tree, select a specified parameter and change its value. You can also enter the parameter name in the **Search** box to search for the parameter and view the result.

5.7.3 Managing Services

You can perform the following operations on MRS:

- Add or delete services.
- Start the service in the **Stopped**, **Stop Failed**, or **Failed to Start** state to use the service.
- Stop the services or stop abnormal services.
- Restart abnormal services or configure expired services to restore or enable the services.

Prerequisites

- **You have configured permissions for the user group to which the IAM users belong.**

  Adding or deleting a service in a cluster is a high-risk operation. Bind the MRS FullAccess, MRS Administrator, Server Administrator, Tenant Guest, MRS Administrator, or Tenant Administrator policy to the user group before you perform this operation. For details about the permissions, see **Synchronizing IAM Users to MRS**.
- **You have synchronized IAM users.** (On the **Dashboard** tab page, click **Synchronize** next to **IAM User Sync** to synchronize IAM users.)

Impact on the System

- The stateful component cannot be added to the task node group.

Adding a Service

Step 1 On the cluster details page, Choose **Components** and click **Add Service**.

Step 2 In the service list, select the services to be added and click **Next**.

NOTE

- When you add a service, the underlying services on which the service depends are automatically selected. You can add multiple services at the same time.
- You can add a service only on a node in normal state.
- If you add Hadoop to a cluster with no Hadoop before, you need to refresh the cluster details page on the MRS console and synchronize IAM users so that jobs can be successfully submitted.
- A single component of the Hadoop service cannot be added to the cluster. Only the Hadoop service can be added. The Hadoop service includes MapReduce, Yarn, and HDFS.
- After the Spark2x component is added, if you need to operate SparkSQL on the Hue web UI, restart the Hue service first.

Step 3 On the **Topology Adjustment** page, select the nodes where the service is to be deployed. For details about the deployment scheme, see **Table 4-9**.

Step 4 Click **OK**. After the service is added, you can view the added service on the **Components** page.

NOTE

The services added on the console are automatically synchronized to Manager.

----End

Deleting a Service

Step 1 On the cluster details page, click **Components**.

Step 2 Locate the row that contains the target service and click **Delete**.

NOTE

- If the service to be deleted has upper-layer dependencies, the service cannot be deleted. Only one service can be deleted at a time.
- You can delete installed services except Hadoop (HDFS, Yarn, and MapReduce), Ranger, DBService, KrbServer, LdapServer, and meta services.

Step 3 In the displayed dialog box, click **Yes** to delete the service.

CAUTION

- The services deleted on the console are automatically synchronized to Manager.
- Before deleting a service, back up the service data to prevent data loss.

----End

Starting, Stopping, and Restarting a Service

Step 1 On the MRS cluster details page, click **Components**.

Step 2 Locate the row that contains the target service, **Start**, **Stop**, and **Restart** to start, stop, or restart the service.

Services are interrelated. If a service is started, stopped, and restarted, services dependent on it will be affected.

The services will be affected in the following ways:

- If a service is to be started, the lower-layer services dependent on it must be started first.
- If a service is stopped, the upper-layer services dependent on it are unavailable.
- If a service is restarted, the running upper-layer services dependent on it must be restarted.

----End

5.7.4 Configuring Service Parameters

On the MRS console, you can view and modify the default service configurations based on site requirements and export or import the configurations.

Impact on the System

- You need to download and update the client configuration files after configuring HBase, HDFS, Hive, Spark, Yarn, and MapReduce service properties.
- The parameters of DBService cannot be modified when only one DBService role instance exists in the cluster.

Prerequisites

You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Modifying Service Parameters

1. On the MRS cluster details page, click **Components**.
2. Select the target service from the service list.
3. Click **Service Configuration**.
4. Switch **Basic** to **All**. All configuration parameters of the service are displayed in the navigation tree. The service name and role names are displayed from upper to lower in the navigation tree.
5. In the navigation tree, select a specified parameter and change its value. You can also enter the parameter name in the **Search** box to search for the parameter and view the result.

   If you want to cancel the modification of a parameter value, click  to restore it.
6. Click **Save Configuration**, save the parameters as prompted, and restart the service.

5.7.5 Configuring Customized Service Parameters

Each component of MRS supports all open-source parameters. MRS supports the modification of some parameters for key application scenarios. Some component clients may not include all parameters with open-source features. To modify the component parameters that are not directly supported by MRS, you can add new parameters for components by using the configuration customization function on MRS. Newly added parameters are saved in component configuration files and take effect after restart.

Impact on the System

- After the service attributes are configured, the service needs to be restarted. The service cannot be accessed during restart.
- You need to download and update the client configuration files after configuring HBase, HDFS, Hive, Spark, Yarn, and MapReduce service properties.

Prerequisites

- You have understood the meanings of parameters to be added, configuration files that have taken effect, and the impact on components.

- You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the MRS cluster details page, click **Components**.

Step 2 Select the target service from the service list.

Step 3 Click **Service Configuration**.

Step 4 In the configuration type drop-down box on the right side, switch **Basic** to **All**.

Step 5 In the navigation tree, select **Customization**. The customized parameters of the current component are displayed on MRS.

The configuration files that save the newly added customized parameters are displayed in the **Parameter File** column. Different configuration files may have same open-source parameters. After the parameters in different files are set to different values, whether the configuration takes effect depends on the loading sequence of the configuration files by components. You can customize parameters for services and roles as required. Adding customized parameters for a single role instance is not supported.

Step 6 Based on the configuration files and parameter functions, locate the row where a specified parameter resides, enter the parameter name supported by the component in the **Parameter** column and enter the parameter value in the **Value** column.

- You can click or to add or delete a custom parameter. You can delete a customized parameter only after you click for the first time.
- If you want to cancel the modification of a parameter value, click to restore it.

Step 7 Click **Save Configuration** and operate as prompted.

----End

Task Example

Configuring Customized Hive Parameters

Hive depends on HDFS. By default, Hive accesses the HDFS client. The configuration parameters to take effect are controlled by HDFS in a unified manner. For example, the HDFS parameter **ipc.client.rpc.timeout** affects the RPC timeout period for all clients to connect to the HDFS server. If you need to modify the timeout period for Hive to connect to HDFS, you can use the configuration customization function. After this parameter is added to the **core-site.xml** file of Hive, this parameter can be identified by the Hive service and its configuration overwrites the parameter configuration in HDFS.

Step 1 On the MRS cluster details page, click **Components**.

Step 2 Choose **Hive** > **Service Configuration**.

Step 3 In the configuration type drop-down box on the right side, switch **Basic** to **All**.

Step 4 In the navigation tree on the left, select **Customization** for the Hive service. The system displays the customized service parameters supported by Hive.

Step 5 In **core-site.xml**, locate the row that contains the **core.site.customized.configs** parameter, enter **ipc.client.rpc.timeout** in the **Parameter** column, and enter a new value in the **Value** column, for example, **150000**. The unit is millisecond.

Step 6 Click **Save Configuration** and operate as prompted.

----End

5.7.6 Synchronizing Service Configuration

Scenario

If **Configuration Status** of some services is **Configuration expired** or **Configuration failed**, synchronize configuration for the cluster or service to restore its configuration status. If all services in the cluster are in the **Configuration failed** state, synchronize the cluster configuration with the background configuration.

Impact on the System

After synchronizing service configurations, you need to restart the services whose configurations have expired. These services are unavailable during restart.

Prerequisites

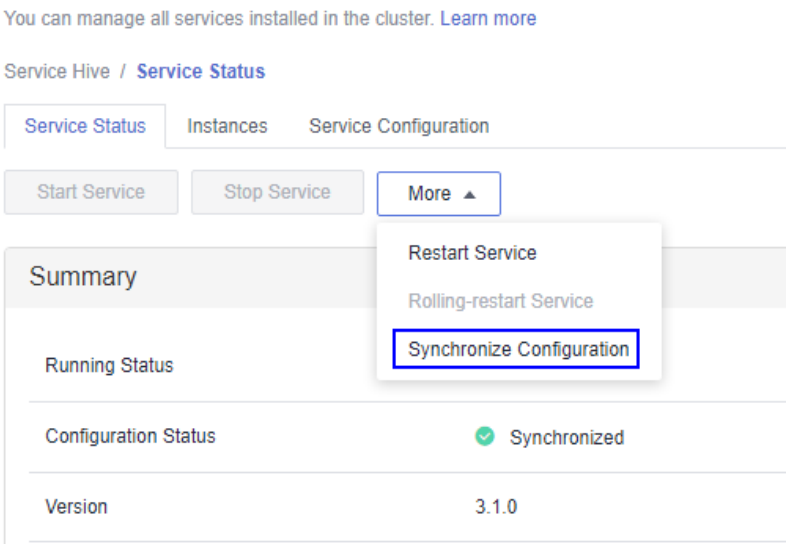
You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the MRS cluster details page, click **Components**.

Step 2 Select the target service from the service list.

Step 3 In the **Service Status** tab, choose **More** > **Synchronize Configuration** and operate as prompted.



----End

5.7.7 Managing Role Instances

Scenario

You can start a role instance that is in the **Stopped**, **Failed to stop** or **Failed to start** status, stop an unused or abnormal role instance or restart an abnormal role instance to recover its functions.

Prerequisites

You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the cluster details page, click the **Components** tab.

Step 2 Select the target service from the service list.

Step 3 Click the **Instances** tab.

Step 4 Select the check box on the left of the target role instance.

Step 5 Click **More**, select operations such as **Start Instance**, **Stop Instance**, **Restart Instance**, **Rolling-restart Instance**, or **Delete Instance** based on site requirements.

----End

5.7.8 Configuring Role Instance Parameters

Scenario

You can view and modify default role instance configuration on MRS based on site requirements. The configurations can be imported and exported.

Impact on the System

You need to download and update the client configuration files after configuring HBase, HDFS, Hive, Spark, Yarn, and MapReduce service properties.

Prerequisites

You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Modifying Role Instance Parameters

1. On the cluster details page, click the **Components** tab.
2. Select the target service from the service list.
3. Click the **Instances** tab.
4. Click the target role instance from the role instance list.
5. Click the **Instance Configuration** tab.
6. Switch **Basic** to **All** from the drop-down list on the right of the page. All configuration parameters of the role instance are displayed in the navigation tree.
7. In the navigation tree, select a specified parameter and change its value. You can also enter the parameter name in the **Search** box to search for the parameter and view the result.

   If you want to cancel the modification of a parameter value, click  to restore it.
8. Click **Save Configuration** and operate as prompted.

5.7.9 Synchronizing Role Instance Configuration

Scenario

When **Configuration Status** of a role instance is **Configuration expired** or **Configuration failed**, you can synchronize the configuration data of the role instance with the background configuration.

Impact on the System

After synchronizing a role instance configuration, you need to restart the role instance whose configuration has expired. The role instance is unavailable during restart.

Prerequisites

You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the cluster details page, click the **Components** tab.

Step 2 Select a service name.

Step 3 Click the **Instances** tab.

Step 4 Click the target role instance from the role instance list.

Step 5 Click **More** and select **Synchronize Configuration** above the role instance status and indicator information.

Step 6 In the dialog box that is displayed, select **Restart the service or instances whose configurations have expired** and click **Yes** to restart the role instance.

----End

5.7.10 Decommissioning and Recommissioning a Role Instance

Scenario

If a Core or Task node is faulty, the cluster status may be displayed as **Abnormal**. In an MRS cluster, data can be stored on different Core nodes. You can decommission the specified role instance on MRS to stop the role instance from providing services. After fault rectification, you can recommission the role instance.

The following role instances can be decommissioned or recommissioned:

- DataNode role instance on HDFS
- NodeManager role instance on Yarn
- RegionServer role instance on HBase
- ClickHouseServer role instance on ClickHouse

Restrictions:

- If the number of the DataNodes is less than or equal to that of HDFS copies, decommissioning cannot be performed. If the number of HDFS copies is three and the number of DataNodes is less than four in the system, decommissioning cannot be performed. In this case, an error will be reported and force MRS to exit the decommissioning 30 minutes after MRS attempts to perform the decommissioning.
- If a role instance is out of service, you must recommission the instance to start it before using it again.

Prerequisites

You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the cluster details page, click the **Components** tab.

Step 2 Click a service in the service list.

Step 3 Click the **Instances** tab.

Step 4 Select an instance.

Step 5 Choose **More** > **Decommission** or **Recommission** to perform the corresponding operation.

NOTE

During the instance decommissioning, if the service corresponding to the instance is restarted in the cluster using another browser, MRS displays a message indicating that the instance decommissioning is stopped, but the **Operating Status** of the instance is displayed as **Started**. In this case, the instance has been decommissioned on the background. You need to decommission the instance again to synchronize the operating status.

----End

5.7.11 Starting and Stopping a Cluster

A cluster is a collection of service components. You can start or stop all services in a cluster.

Prerequisites

You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

On the cluster details page, choose **Management Operations** > **Start All Components** or **Stop All Components** in the upper right corner to perform the required operation.

5.7.12 Performing Rolling Restart

After modifying the configuration items of a big data component, you need to restart the corresponding service to make new configurations take effect. If you use a normal restart mode, all services or instances are restarted concurrently, which may cause service interruption. To ensure that services are not affected during service restart, you can restart services or instances in batches by rolling restart. For instances in active/standby mode, a standby instance is restarted first and then an active instance is restarted. Rolling restart takes longer than normal restart.

Table 5-42 provides services and instances that support or do not support rolling restart in the MRS cluster.

Table 5-42 Services and instances that support or do not support rolling restart

Service	Instance	Support Rolling Restart
Alluxio	AlluxioJobMaster	Yes
	AlluxioMaster	
ClickHouse	ClickHouseServer	Yes
	ClickHouseBalancer	
CDL	CDLConnector	Yes
	CDLService	
Flink	FlinkResource	No
	FlinkServer	
Flume	Flume	Yes
	MonitorServer	
Guardian	TokenServer	Yes
HBase	HMaster	Yes
	RegionServer	
	ThriftServer	
	RESTServer	
HetuEngine	HSBroker	Yes
	HSConsole	
	HSFabric	
	QAS	
HDFS	NameNode	Yes
	Zkfc	
	JournalNode	
	HttpFS	
	DataNode	
Hive	MetaStore	Yes
	WebHCat	
	HiveServer	
Hue	Hue	No
Impala	Impalad	No

Service	Instance	Support Rolling Restart
	StateStore	
	Catalog	
IoTDB	IoTDBServer	Yes
Kafka	Broker	Yes
	KafkaUI	No
Kudu	KuduTserver	Yes
	KuduMaster	
Loader	Sqoop	No
MapReduce	JobHistoryServer	Yes
Oozie	oozie	No
Presto	Coordinator	Yes
	Worker	
Ranger	RangerAdmin	Yes
	UserSync	
	TagSync	
Spark	JobHistory	Yes
	JDBCServer	
	SparkResource	
Storm	Nimbus	Yes
	UI	
	Supervisor	
	Logviewer	
Tez	TezUI	No
Yarn	ResourceManager	Yes
	NodeManager	
Zookeeper	Quorumpeer	Yes

Restrictions

- Perform a rolling restart during off-peak hours.

  - Otherwise, a rolling restart failure may occur. For example, if the throughput of Kafka is high (over 100 MB/s) during the Kafka rolling restart, the Kafka rolling restart may fail.
  - For example, if the requests per second of each RegionServer on the native interface exceed 10,000 during the HBase rolling restart, you need to increase the number of handles to prevent a RegionServer restart failure caused by heavy loads during the restart.
- Before the restart, check the number of current requests of HBase. If the number of requests of each RegionServer on the native interface exceeds 10,000, increase the number of handles to prevent a failure.
- If the number of Core nodes in a cluster is less than six, services may be affected for a short period of time.
- Preferentially perform a rolling instance or service restart and select **Only restart instances whose configurations have expired**.

Performing a Rolling Service Restart

Step 1 Choose **Clusters** > **Active Clusters** and click a cluster name to go to the cluster details page.

Step 2 Click **Components** and select a service for which you want to perform a rolling restart.

Step 3 On the **Service Status** tab page, click **More** and select **Rolling-restart Service**.

Step 4 The **Rolling-restart Service** page is displayed. Select **Only restart instances whose configurations have expired** and click **OK** to perform rolling restart for the service.

Step 5 After the rolling restart task is complete, click **Finish**.

----End

Performing a Rolling Instance Restart

Step 1 Choose **Clusters** > **Active Clusters** and click a cluster name to go to the cluster details page.

Step 2 Click **Components** and select a service for which you want to perform a rolling restart.

Step 3 On the **Instance** tab page, select the instance to be restarted. Click **More** and select **Rolling-restart Instance**.

Step 4 After you enter the administrator password, the **Rolling-restart Instance** page is displayed. Select **Only restart instances whose configurations have expired** and click **OK** to perform rolling restart for the instance.

Step 5 After the rolling restart task is complete, click **Finish**.

----End

Perform a Rolling Cluster Restart

Step 1 Choose **Clusters** > **Active Clusters** and click a cluster name to go to the cluster details page.

Step 2 In the upper right corner of the page, choose **Management Operations** > **Perform Rolling Cluster Restart**.

Step 3 The **Rolling-restart Cluster** page is displayed. Select **Only restart instances whose configurations have expired** and click **OK** to perform rolling restart for the cluster.

Step 4 After the rolling restart task is complete, click **Finish**.

----End

Rolling Restart Parameter Description

Table 5-43 describes rolling restart parameters.

Table 5-43 Rolling restart parameter description

Parameter	Description
Only restart instances whose configurations have expired	Specifies whether to restart only the modified instances in a cluster.
Enable rack strategy	Whether to enable the concurrent rack rolling restart strategy. This parameter takes effect only for roles that meet the rack rolling restart strategy. (The roles support rack awareness, and instances of the roles belong to two or more racks.)
Data Node Instances to Be Batch Restarted	Specifies the number of instances that are restarted in each batch when the batch rolling restart strategy is used. The default value is **1**. The value ranges from 1 to 20. This parameter is valid only for data nodes.
Batch Interval	Specifies the interval between two batches of instances for rolling restart. The default value is **0**. The value ranges from 0 to 2147483647. The unit is second. Note: Setting the batch interval parameter can increase the stability of the big data component process during the rolling restart. You are advised to set this parameter to a non-default value, for example, 10.
Decommissioning Timeout Interval	Decommissioning interval for role instances during a rolling restart.

Parameter	Description
Batch Fault Tolerance Threshold	Specifies the tolerance times when the rolling restart of instances fails to be executed in batches. The default value is **0**, which indicates that the rolling restart task ends after any batch of instances fails to be restarted. The value ranges from 0 to 2147483647.

Procedure in a Typical Scenario

Step 1 Choose **Clusters** > **Active Clusters** and click a cluster name to go to the cluster details page.

Step 2 Click **Components** and select **HBase**. The **HBase** service page is displayed.

Step 3 Click the **Service Configuration** tab, modify an HBase parameter, and save the configuration as prompted.

Step 4 After saving the configurations, click **Finish**.

Step 5 Click the **Service Status** tab.

Step 6 On the **Service Status** tab page, click **More** and select **Rolling-restart Service**.

Step 7 After you enter the administrator password, the **Rolling-restart Service** page is displayed. Select **Only restart instances whose configurations have expired** and click **OK** to perform rolling restart.

Step 8 After the rolling restart task is complete, click **Finish**.

----End

5.8 Alarm Management

5.8.1 Viewing the Alarm List

The alarm list displays all alarms in the MRS cluster. The MRS page displays the alarms that need to be handled in a timely manner and the events.

On the MRS management console, you can only query basic information about uncleared MRS alarms on the **Alarms** tab page. For details about how to view alarm details or manage alarms, see **Viewing and Manually Clearing an Alarm**.

Alarms are listed in chronological order by default in the alarm list, with the most recent alarms displayed at the top.

Table 5-44 describes various fields in an alarm.

Table 5-44 Alarm description

Parameter	Description
Alarm ID	ID of an alarm.

Parameter	Description
Alarm Name	Name of an alarm.
Severity	Alarm severity. The alarm severity of a cluster is as follows: ● Critical Indicates alarms reporting errors that affect cluster running, such as unavailable cluster services, node faults, data inconsistency between the active and standby GaussDB databases, and abnormal LdapServer data synchronization. You need to check the cluster status based on the alarms and rectify the faults in a timely manner. ● Major Indicates alarms reporting errors that affect some cluster functions, including process faults, periodic backup task failures, and abnormal key file permissions. Check the objects for which the alarms are generated based on the alarms and clear the alarms in a timely manner. ● Minor Indicates alarms reporting errors that do not affect major functions of the current cluster, including alarms indicating that the certificate file is about to expire, audit logs fail to be dumped, and the license file is about to expire. ● Suggestion Indicates an alarm of the lowest severity. It is used for information display or prompt and indicates that an event occurs in the scenarios when you stop a service, delete a service, stop an instance, delete an instance, delete a node, restart a service, restart an instance, perform an active/standby switchover for MRS Manager, scale in a host, or restore an instance. Additionally, this type of alarms also occurs when an instance is faulty, a job executed successfully, or a job failed to be executed.
Generated	Time when the alarm is generated.
Location	Details about the alarm.
Operation	If the alarm can be manually cleared, click **Clear Alarm**. To view details about an alarm, click **View Help**.

Table 5-45 Button description

Button	Description
	Select an interval for refreshing the alarm list from the drop-down list. • Refresh every 30s • Refresh every 60s • Stop refreshing
	Select an alarm severity from the drop-down list box to filter alarms. You can filter the following alarms: All, Critical, Major, Minor, and Warning.
	Click  and manually refresh the alarm list.
Advanced Search	Click **Advanced Search**. In the displayed alarm search area, set search criteria and click **Search** to view the information about specified alarms. You can click **Reset** to clear the search criteria.

5.8.2 Viewing the Event List

The event list displays information about all events in a cluster, such as service restart and service termination.

Events are listed in the event list in chronological order by default, with the most recent events displayed at the top.

NOTE

You can view the event list when IAM user synchronization is complete.

Table 5-46 describes various fields for an event.

Table 5-46 Event description

Parameter	Description
Event ID	Specifies the ID of an event.
Event Severity	Specifies the event severity. The event level of a cluster is as follows: • Critical • Major • Minor • Suggestion
Event Name	Name of the generated event.

Parameter	Description
Generated	Time when the event is generated.
Location	Specifies the detailed information for locating the event,

Table 5-47 Icon description

Icon	Description
	Select an interval for refreshing the event list from the drop-down list. • Refresh every 30s • Refresh every 60s • Stop refreshing
	Click  to manually refresh the event list.
Advanced Search	Click **Advanced Search**. In the displayed event search area, set search criteria and click **Search** to view the information about specified events. Click **Reset** to clear the search criteria.

Exporting events

Step 1 Choose **Clusters > Active Clusters** and click a cluster name to go to the cluster details page.

Step 2 Click **Alarm Management** > **Events**.

Step 3 Click **Export All**.

Step 4 In the displayed dialog box, select the type and click **OK**.

----End

Common Events

Table 5-48 Common events

Event ID	Event Name
12019	Stop Service
12020	Delete Service
12021	Stop RoleInstance
12022	Delete RoleInstance

Event ID	Event Name
12023	Delete Node
12024	Restart Service
12025	Restart RoleInstance
12026	Manager Switchover
12065	Restart Process
12070	Job Running Succeeded
12071	Job Running Failed
12072	Job Killed
12086	Restart Agent
12152	Start Periodic Replication
12153	Periodic Replication Completed
12154	Start Streaming Replication
12155	Restart Streaming Replication
12156	Stop Streaming Replication
12157	Skip Periodic Synchronization
14005	NameNode Switchover
14028	HDFS DiskBalancer Task
14029	Active NameNode Entered Security Mode and Generated New Fsimage
17001	Oozie Workflow Execution Failure
17002	Oozie Scheduled Job Execution Failure
18001	ResourceManager Switchover
18004	JobHistoryServer Switchover
19001	HMaster Failover
20003	Hue Failover
24002	Flume Channel Overflow
25001	LdapServer Failover
27000	DBServer Switchover
29001	Impala HaProxy Active/Standby Switchover
29002	Impala StateStoreCatalog Active/Standby Switchover

Event ID	Event Name
38003	Adjust Topic Data Storage Period
43014	Spark2x Data Skew
43015	Spark2x SQL Large Query Results
43016	Spark2x SQL Execution Timeout
43024	Start JDBCServer
43025	Stop JDBCServer
43026	ZooKeeper Connection Succeeded
43027	Zookeeper Connection Failed
44003	Coordinator Switchover

5.8.3 Viewing and Manually Clearing an Alarm

Scenario

You can view and clear alarms on MRS.

Generally, the system automatically clears an alarm when the fault is rectified. If the fault has been rectified and the alarm cannot be automatically cleared, you can manually clear the alarm.

You can view the latest 100,000 alarms (including uncleared, manually cleared, and automatically cleared alarms) on MRS. If the number of cleared alarms exceeds 100,000 and is about to reach 110,000, the system automatically dumps the earliest 10,000 cleared alarms to the dump path.

The path is **${BIGDATA_HOME}/om-server/OMS/workspace/data** of the active management node.

A directory is automatically generated when alarms are dumped for the first time.

NOTE

Set an automatic refresh interval or click for an immediate refresh.

The following refresh interval options are supported:

- Refresh every 30 seconds
- Refresh every 60 seconds
- Stop refreshing

Procedure

Step 1 Choose **Clusters > Active Clusters** and click a cluster name to go to the cluster details page.

Step 2 Click **Alarms** and view the alarm information in the alarm list.

Step 3 Click **Advanced Search**. In the displayed alarm search area, set search criteria and click **Search** to view the information about specified alarms. You can click **Reset** to clear the search criteria.

NOTE

The start time and end time are specified in **Time Range**. You can search for alarms generated within the time range.

Handle the alarm by referring to **Alarm Reference**. If the alarms in some scenarios are generated due to other cloud services that MRS depends on, you need to contact maintenance personnel of the corresponding cloud services.

Step 4 Click **Clear Alarm** if you need to. In the displayed dialog box, click **OK**.

NOTE

If multiple alarms have been handled, you can select one or more alarms to be cleared and click **Clear Alarm** to clear the alarms in batches. A maximum of 300 alarms can be cleared in each batch.

----End

Exporting Alarms

Step 1 Choose **Clusters > Active Clusters** and click a cluster name to go to the cluster details page.

Step 2 Click **Alarm Management** > **Alarms**.

Step 3 Click **Export All**.

Step 4 In the displayed dialog box, select the type and click **OK**.

----End

5.9 Tenant Management

5.9.1 Overview

Definition

An MRS cluster provides various resources and services for multiple organizations, departments, or applications to share. The cluster provides tenants as a logical entity to use these resources and services. A mode involving different tenants is called multi-tenant mode. Currently, only the analysis cluster supports tenant management.

Principles

The MRS cluster provides the multi-tenant function. It supports a layered tenant model and allows dynamic adding or deleting of tenants to isolate resources. It dynamically manages and configures tenants' computing and storage resources.

The computing resources indicate tenants' Yarn task queue resources. The task queue quota can be modified, and the task queue usage status and statistics can be viewed.

The storage resources can be stored on HDFS. You can add and delete the HDFS storage directories of tenants, and set the quotas of file quantity and the storage space of the directories.

Tenants can create and manage tenants in a cluster based on service requirements.

- Roles, computing resources, and storage resources are automatically created when tenants are created. By default, all permissions of the new computing resources and storage resources are allocated to a tenant's roles.
- Permissions to view the current tenant's resources, add a subtenant, and manage the subtenant's resources are granted to the tenant's roles by default.
- After you have modified the tenant's computing or storage resources, permissions of the tenant's roles are automatically updated.

MRS supports a maximum of 512 tenants. The default tenants created by the system include **default**. Tenants that are in the topmost layer with the default tenant are called level-1 tenants.

Resource Pools

Yarn task queues support only the label-based scheduling policy. This policy enables Yarn task queues to associate NodeManagers that have specific node labels. In this way, Yarn tasks run on specified nodes so that tasks are scheduled and certain hardware resources are utilized. For example, Yarn tasks requiring a large memory capacity can run on nodes with a large memory capacity by means of label association, preventing poor service performance.

In an MRS cluster, the tenant logically divides Yarn cluster nodes to combine multiple NodeManagers into a resource pool. Yarn task queues can be associated with specified resource pools by configuring queue capacity policies, ensuring efficient and independent resource utilization in the resource pools.

MRS supports a maximum of 50 resource pools. By default, the system contains a **default** resource pool.

5.9.2 Creating a Tenant

Scenario

You can create a tenant on MRS Manager to specify the resource usage.

Prerequisites

- A tenant name has been planned. The name must not be the same as that of a role or Yarn queue that exists in the current cluster.
- If a tenant requires storage resources, a storage directory has been planned based on service requirements, and the planned directory does not exist under the HDFS directory.

- The resources that can be allocated to the current tenant have been planned and the sum of the resource percentages of direct sub-tenants under the parent tenant at every level does not exceed 100%.
- You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the MRS cluster details page, click **Tenants**.

Step 2 Click **Create Tenant**. On the page that is displayed, configure tenant properties. The following table takes MRS 3.x versions as an example.

Table 5-49 Tenant parameters

Parameter	Description
Name	Name of the current tenant. The value consists of 3 to 50 characters, and can contain letters, digits, and underscores (_).
Tenant Type	**Leaf** or **Non-leaf** tenant. If **Leaf** is selected, the current tenant is a leaf tenant and no sub-tenant can be added. If **Non-leaf** is selected, sub-tenants can be added to the current tenant.
Compute Resource	Compute resources can be used by the tenant. The system automatically creates a task queue named after the tenant name in Yarn. If **Yarn** is not selected, the system does not automatically create a task queue.

Parameter	Description
Configuration Mode	If **Yarn** is selected for **Compute Resource**, this parameter can be set to **Basic** or **Advanced**. • **Basic**: Configure the percentage of compute resources used by the tenant in the default resource pool by specifying **Default Resource Pool Capacity (%)**. • **Advanced**: Configure the following parameters for advanced settings: – **Weight**: Tenant resource weight. The value ranges from 0 to 100. Tenant resource weight = Tenant weight/Total weight of tenants at the same level – **Minimum Resources**: resources preempted by the tenant. The value is a percentage or absolute value of the parent tenant's resources. When a tenant's workload is light, their resources are automatically lent to other tenants. When available resources are fewer than **Minimum Resources**, the tenant can preempt the resources that were lent out. – **Maximum Resources**: maximum resources that can be used by a tenant. The value is a percentage or absolute value of the parent tenant's resources. – **Reserved Resources**: resources reserved for the tenant. The reserved resources cannot be used by other tenants even if no job is using resources of the tenant. The value is a percentage or absolute value of the parent tenant's resources.
Default Resource Pool Capacity (%)	Specifies the percentage of the computing resources used by the current tenant in the **default** resource pool. This parameter is required when **Configuration Mode** is **Basic**.
Storage Resource	Specifies storage resources for the current tenant. The system automatically creates a file folder named after the tenant name in the **/tenant** directory. When a tenant is created for the first time, the system automatically creates the **/tenant** directory in the HDFS root directory. If storage resources are not **HDFS**, the system does not create a storage directory under the root directory of HDFS.
Maximum Number of Files/Directories	Maximum number of files or directories that can be created in HDFS.

Parameter	Description
Storage Space Quota	Specifies the quota for HDFS storage space used by the current tenant. The value ranges from **1** to **8796093022208**. The unit is MB or GB. This parameter indicates the maximum HDFS storage space that can be used by a tenant, but does not indicate the actual space used. If the value is greater than the size of the HDFS physical disk, the maximum space available is the full space of the HDFS physical disk. **NOTE** To ensure data reliability, one backup is automatically generated for each file saved in HDFS, that is, two copies are generated in total. The HDFS storage space indicates the total disk space occupied by all these copies. For example, if the value is set to **500** MB, the actual space for storing files is about 250 MB (500/2 = 250).
Storage Path	Specifies the tenant's HDFS storage directory. The system automatically creates a file folder named after the tenant name in the **/tenant** directory by default. For example, the default HDFS storage directory for **ta1** is **tenant/ta1**. When a tenant is created for the first time, the system automatically creates the **/tenant** directory in the HDFS root directory. The storage path is customizable.
Service	Specifies other service resources associated with the current tenant. HBase is supported. To configure this parameter, click **Associate Services**. In the dialog box that is displayed, set **Service** to **HBase**. If **Association Mode** is set to **Exclusive**, service resources are occupied exclusively. If **share** is selected, service resources are shared.
Description	Specifies the description of the current tenant.

Step 3 Click **OK** to save the settings.

It takes a few minutes to save the settings. If the **Tenant created successfully** is displayed in the upper-right corner, the tenant is added successfully. The tenant is created successfully.

NOTE

- Roles, computing resources, and storage resources are automatically created when tenants are created.
- The new role has permissions on the computing and storage resources. The role and its permissions are controlled by the system automatically and cannot be controlled manually under **Manage Role**.
- If you want to use the tenant, create a system user and assign the Manager_tenant role and the role corresponding to the tenant to the user. For details, see **Creating a User**.

----End

Related Tasks

View an added tenant.

Step 1 On the MRS details page, click **Tenants**.

Step 2 In the tenant list on the left, click the name of the added tenant.

The **Summary** tab is displayed on the right by default.

Step 3 View **Basic Information**, **Resource Quota**, and **Charts** of the tenant.

If HDFS is in the **Stopped** state, **Available** and **Used** of **Space** in **Resource Quota** are **unknown.**

----End

5.9.3 Creating a Sub-tenant

Scenario

You can create a sub-tenant on MRS if the resources of the current tenant need to be further allocated.

Prerequisites

- A parent tenant has been added.
- A tenant name has been planned. The name must not be the same as that of a role or Yarn queue that exists in the current cluster.
- If a sub-tenant requires storage resources, a storage directory has been planned based on service requirements, and the planned directory does not exist under the storage directory of the parent tenant.
- The resources that can be allocated to the current tenant have been planned and the sum of the resource percentages of direct sub-tenants under the parent tenant at every level does not exceed 100%.
- You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the MRS details page, click **Tenants**.

Step 2 In the tenant list on the left, move the cursor to the tenant node to which a sub-tenant is to be added. Click **Create sub-tenant**. On the displayed page, configure the sub-tenant attributes according to the following table which takes MRS 3.x versions as an example.

Table 5-50 Sub-tenant parameters

Parameter	Description
Parent tenant	Specifies the name of the parent tenant.

Parameter	Description
Name	Specifies the name of the current tenant. The value consists of 3 to 20 characters, and can contain letters, digits, and underscores (_).
Tenant Type	The options include **Leaf** and **Non-leaf**. If **Leaf** is selected, the current tenant is a leaf tenant and no sub-tenant can be added. If **Non-leaf** is selected, sub-tenants can be added to the current tenant.
Compute Resource	Specifies the dynamic computing resources for the current tenant. The system automatically creates a task queue named after the sub-tenant name in the Yarn parent queue. If **Yarn** is not selected, the system does not automatically create a task queue. If the parent tenant does not have compute resources, the sub-tenant cannot use compute resources.
Configuration Mode	If **Yarn** is selected for **Compute Resource**, this parameter can be set to **Basic** or **Advanced**. ● **Basic**: Configure the percentage of compute resources used by the tenant in the default resource pool by specifying **Default Resource Pool Capacity (%)**. ● **Advanced**: Configure the following parameters for advanced settings: – **Weight**: Tenant resource weight. The value ranges from 0 to 100. Tenant resource weight = Tenant weight/Total weight of tenants at the same level – **Minimum Resources**: resources preempted by the tenant. The value is a percentage or absolute value of the parent tenant's resources. When a tenant's workload is light, their resources are automatically lent to other tenants. When available resources are fewer than **Minimum Resources**, the tenant can preempt the resources that were lent out. – **Maximum Resources**: maximum resources that can be used by a tenant. The value is a percentage or absolute value of the parent tenant's resources. – **Reserved Resources**: resources reserved for the tenant. The value is a percentage or absolute value of the parent tenant's resources.
Default Resource Pool Capacity (%)	Specifies the percentage of the resources used by the current tenant. The base value is the total resources of the parent tenant. This parameter is required when **Configuration Mode** is **Basic**.

Parameter	Description
Storage Resource	Specifies storage resources for the current tenant. The system automatically creates a file in the HDFS parent tenant directory. The file is named the same as the name of the sub-tenant. If storage resources are not **HDFS**, the system does not create a storage directory under the root directory of HDFS. If the parent tenant does not have storage resources, the sub-tenant cannot use storage resources.
Maximum Number of Files/Directories	Maximum number of files or directories that can be created in HDFS.
Storage Space Quota	Specifies the quota for HDFS storage space used by the current tenant. The minimum value is **1**, and the maximum value is the total storage quota of the parent tenant. The unit is MB or GB. This parameter indicates the maximum HDFS storage space that can be used by a tenant, but does not indicate the actual space used. If the value is greater than the size of the HDFS physical disk, the maximum space available is the full space of the HDFS physical disk. If the quota is greater than the quota of the parent tenant, the actual storage capacity is subject to the quota of the parent tenant. **NOTE** To ensure data reliability, one backup is automatically generated for each file saved in HDFS, that is, two copies are generated in total. The HDFS storage space indicates the total disk space occupied by all these copies. For example, if the value is set to **500** MB, the actual space for storing files is about 250 MB (500/2 = 250).
Storage Path	Specifies the tenant's HDFS storage directory. The system automatically creates a file folder named after the sub-tenant name in the directory of the parent tenant by default. For example, if the sub-tenant is **ta1s** and the parent directory is **tenant/ta1**, the system sets this parameter for the sub-tenant to **tenant/ta1/ta1s**. The storage path is customizable in the parent directory. The parent directory for the storage path must be the storage directory of the parent tenant.
Service	Specifies other service resources associated with the current tenant. HBase is supported. To configure this parameter, click **Associate Services**. In the dialog box that is displayed, set **Service** to **HBase**. If **Association Mode** is set to **Exclusive**, service resources are occupied exclusively. If **share** is selected, service resources are shared.
Description	Specifies the description of the current tenant.

Step 3 Click **OK** to save the settings.

It takes a few minutes to save the settings. If the **Tenant created successfully** is displayed in the upper-right corner, the tenant is added successfully. The tenant is created successfully.

NOTE

- Roles, computing resources, and storage resources are automatically created when tenants are created.
- The new role has permissions on the computing and storage resources. The role and its permissions are controlled by the system automatically and cannot be controlled manually under **Manage Role**.
- When using this tenant, create a system user and assign the user a related tenant role. For details, see **Creating a User**.

----End

5.9.4 Deleting a Tenant

Scenario

You can delete a tenant that is not required on MRS.

Prerequisites

- A tenant has been added.
- You have checked whether the tenant to be deleted has sub-tenants. If the tenant has sub-tenants, delete them; otherwise, you cannot delete the tenant.
- The role of the tenant to be deleted cannot be associated with any user or user group.
- You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the MRS details page, click **Tenants**.

Step 2 In the tenant list on the left, move the cursor to the tenant node to be deleted and click **Delete**.

The **Delete Tenant** dialog box is displayed. If you want to save the tenant data, select **Reserve the data of this tenant**. Otherwise, the tenant's storage space will be deleted.

Step 3 Click **OK**.

It takes a few minutes to save the configuration. After the tenant is deleted successfully, the role and storage space of the tenant are also deleted.

NOTE

- After the tenant is deleted, the task queue of the tenant still exists in Yarn.
- If you choose not to reserve data when deleting the parent tenant, data of sub-tenants is also deleted if the sub-tenants use storage resources.

----End

5.9.5 Managing a Tenant Directory

Scenario

You can manage the HDFS storage directory used by a specific tenant on MRS. The management operations include adding a tenant directory, modifying the directory file quota, modifying the storage space, and deleting a directory.

Prerequisites

- A tenant associated with HDFS storage resources has been added.
- You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

- View a tenant directory.
  a. On the MRS details page, click **Tenants**.
  b. In the tenant list on the left, click the target tenant.
  c. Click the **Resources** tab.
  d. View the **HDFS Storage** table.
     - The **Maximum Number of Files/Directories** column indicates the quotas for the file and directory quantity of the tenant directory.
     - The **Space Quota** column indicates storage space size of tenant directories.
- Add a tenant directory.
  a. On the MRS details page, click **Tenants**.
  b. In the tenant list on the left, click the tenant whose HDFS storage directory needs to be added.
  c. Click the **Resources** tab.
  d. In the **HDFS Storage** table, click **Create Directory**.
     - Set **Path** to a tenant directory path.

       NOTE

       - If the current tenant is not a sub-tenant, the new path is created in the HDFS root directory.
       - If the current tenant is a sub-tenant, the new path is created in the specified directory.

A complete HDFS storage directory can contain a maximum of 1,023 characters. An HDFS directory name contains digits, letters, spaces, and underscores (_). The name cannot start or end with a space.

- Set **Maximum Number of Files/Directories** to the quotas of file and directory quantity.

  Maximum Number of Files/Directories is optional. Its value ranges from **1** to **9223372036854775806**.

- Set **Storage Space Quota** to the storage space size of the tenant directory.

  The value of **Storage Space Quota** ranges from **1** to **8796093022208**.

  NOTE

  To ensure data reliability, one backup is automatically generated for each file saved in HDFS, that is, two copies are generated in total. The HDFS storage space indicates the total disk space occupied by all these copies. For example, if the value of **Storage Space Quota** is set to **500**, the actual space for storing files is about 250 MB (500/2 = 250).

e. Click **OK**. The system creates tenant directories in the HDFS root directory.

- Modify a tenant directory.
  a. On the MRS details page, click **Tenants**.
  b. In the tenant list on the left, click the tenant whose HDFS storage directory needs to be modified.
  c. Click the **Resources** tab.
  d. In the **HDFS Storage** table, click **Modify** in the **Operation** column of the specified tenant directory.

     - Set **Maximum Number of Files/Directories** to the quotas of file and directory quantity.

       Maximum Number of Files/Directories is optional. Its value ranges from **1** to **9223372036854775806**.

     - Set **Storage Space Quota** to the storage space size of the tenant directory.

       The value of **Storage Space Quota** ranges from **1** to **8796093022208**.

       NOTE

       To ensure data reliability, one backup is automatically generated for each file saved in HDFS, that is, two copies are generated in total. The HDFS storage space indicates the total disk space occupied by all these copies. For example, if the value of **Storage Space Quota** is set to **500**, the actual space for storing files is about 250 MB (500/2 = 250).

  e. Click **OK**.
- Delete a tenant directory.
  a. On the MRS details page, click **Tenants**.
  b. In the tenant list on the left, click the tenant whose HDFS storage directory needs to be deleted.

c. Click the **Resources** tab.

d. In the **HDFS Storage** table, click **Delete** in the **Operation** column of the specified tenant directory.

The default HDFS storage directory set during tenant creation cannot be deleted. Only the newly added HDFS storage directory can be deleted.

e. Click **OK**. The tenant directory is deleted.

5.9.6 Restoring Tenant Data

Scenario

Tenant data is stored on Manager and in cluster components by default. When components are restored from faults or reinstalled, some tenant configuration data may be abnormal. In this case, you can manually restore the tenant data.

Prerequisites

You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the MRS details page, click **Tenants**.

Step 2 In the tenant list on the left, click a tenant node.

Step 3 Check the status of the tenant data.

1. In **Summary**, check the color of the circle on the left of **Basic Information**. Green indicates that the tenant is available and gray indicates that the tenant is unavailable.
2. Click **Resources** and check the circle on the left of **Yarn** or **HDFS Storage**. Green indicates that the resource is available, and gray indicates that the resource is unavailable.
3. Click **Service Association** and check the **Status** column of the associated service table. **Good** indicates that the component can provide services for the associated tenant. **Bad** indicates that the component cannot provide services for the tenant.
4. If any check result is abnormal, go to **Step 4** to restore tenant data.

Step 4 Click **Restore Tenant Data**.

Step 5 In the **Restore Tenant Data** window, select one or more components whose data needs to be restored. Click **OK**. The system automatically restores the tenant data.

----End

5.9.7 Creating a Resource Pool

Scenario

In an MRS cluster, users can logically divide Yarn cluster nodes to combine multiple NodeManagers into a Yarn resource pool. Each NodeManager belongs to

one resource pool only. The system contains a **default** resource pool by default. All NodeManagers that are not added to customized resource pools belong to this resource pool.

You can create a customized resource pool on MRS and add hosts that have not been added to other customized resource pools to it.

Prerequisites

You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the MRS details page, click **Tenants**.

Step 2 Click the **Resource Pools** tab.

Step 3 Click **Create Resource Pool**.

Step 4 In **Create Resource Pool**, set the properties of the resource pool.

- **Name**: Enter a name for the resource pool. The name of the newly created resource pool cannot be **default**.

  The name consists of 1 to 20 characters and can contain digits, letters, and underscores (_) but cannot start with an underscore (_).
- **Resource Label**: Enter the resource label of the resource pool. The value can contain 1 to 50 characters, including digits, letters, underscores (_), and hyphens (-), and must start with a digit or letter.
- **Available Hosts**: In the host list on the left, select a specified host name and add it to the resource pool. Only hosts in the cluster can be selected. The host list of a resource pool can be left blank.

Step 5 Click **OK**.

Step 6 After a resource pool is created, users can view the **Name**, **Members**, **Type**, **vCore** and **Memory** in the resource pool list. Hosts that are added to the customized resource pool are no longer members of the **default** resource pool.

----End

5.9.8 Modifying a Resource Pool

Scenario

You can modify members of an existing resource pool on MRS.

Prerequisites

You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the MRS details page, click **Tenants**.

Step 2 Click the **Resource Pools** tab.

Step 3 Locate the row that contains the specified resource pool, and click **Modify** in the **Operation** column.

Step 4 In **Modify Resource Pool**, modify **Added Hosts**.

- Adding a host: In the host list on the left, select the specified host name and add it to the resource pool.
- Deleting a host: In the host list on the right, click  next to a host to remove the host from the resource pool. The host list of a resource pool can be left blank.

Step 5 Click **OK**.

----End

5.9.9 Deleting a Resource Pool

Scenario

You can delete an existing resource pool on MRS.

Prerequisites

- Any queue in a cluster cannot use the resource pool to be deleted as the default resource pool. Before deleting the resource pool, cancel the default resource pool. For details, see **Configuring a Queue**.
- Resource distribution policies of all queues have been cleared from the resource pool being deleted. For details, see **Clearing Configuration of a Queue**.
- You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the MRS details page, click **Tenant**.

Step 2 Click the **Resource Pools** tab.

Step 3 Locate the row that contains the specified resource pool, and click **Delete** in the **Operation** column.

In the displayed dialog box, click **OK**.

----End

5.9.10 Configuring a Queue

Scenario

You can modify the queue configuration of a specified tenant on MRS based on service requirements.

Prerequisites

- A tenant associated with Yarn and allocated dynamic resources has been added.
- You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the MRS details page, click **Tenants**.

Step 2 Click the **Queue Configuration** tab.

Step 3 In the tenant queue table, click **Modify** in the **Operation** column of the specified tenant queue.

NOTE

- In the tenant list on the left of the **Tenant Management** tab, click the target tenant. In the window that is displayed, choose **Resource**. On the page that is displayed, click to open the queue modification page.
- A queue can be bound to only one non-default resource pool.

Table 5-51 Queue configuration parameters

Parameter	Description
Max Master Shares (%)	Indicates the maximum percentage of resources occupied by all ApplicationMasters in the current queue.
Max Allocated vCores	Indicates the maximum number of cores that can be allocated to a single YARN container in the current queue. The default value is **-1**, indicating that the number of cores is not limited within the value range.
Max Allocated Memory (MB)	Indicates the maximum memory that can be allocated to a single Yarn container in the current queue. The default value is **-1**, indicating that the memory is not limited within the value range.
Max Running Apps	Maximum number of tasks that can be executed at the same time in the current queue. The default value is **-1**, indicating that the number is not limited within the value range (the meaning is the same if the value is empty). The value 0 indicates that the task cannot be executed. The value ranges from -1 to 2147483647.

Parameter	Description
Max Running Apps per User	Maximum number of tasks that can be executed by each user in the current queue at the same time. The default value is **-1**, indicating that the number is not limited within the value range. If the value is **0**, the task cannot be executed. The value ranges from -1 to 2147483647.
Max Pending Apps	Maximum number of tasks that can be suspended at the same time in the current queue. The default value is **-1**, indicating that the number is not limited within the value range (the meaning is the same if the value is empty). The value **0** indicates that tasks cannot be suspended. The value ranges from -1 to 2147483647.
Resource Allocation Rule	Indicates the rule for allocating resources to different tasks of a user. The rule can be FIFO or FAIR. If a user submits multiple tasks in the current queue and the rule is FIFO, the tasks are executed one by one in sequential order. If the rule is FAIR, resources are evenly allocated to all tasks.
Default Resource Label	Indicates that tasks are executed on a node with a specified resource label. **NOTE** If you need to use a new resource pool, change the default label to the new resource pool label.
Active	• **ACTIVE**: indicates that the current queue can receive and execute tasks. • **INACTIVE**: indicates that the current queue can receive but cannot execute tasks. Tasks submitted to the queue are suspended.
Open	• **OPEN**: indicates that the current queue is opened. • **CLOSED**: indicates that the current queue is closed. Tasks submitted to the queue are rejected.

----End

5.9.11 Configuring the Queue Capacity Policy of a Resource Pool

Scenario

After a resource pool is added, the capacity policies of available resources need to be configured for Yarn task queues. This ensures that tasks in the resource pool are running properly. Each queue can be configured with the queue capacity policy of only one resource pool. Users can view the queues in any resource pool and configure queue capacity policies. After the queue policies are configured, Yarn task queues and resource pools are associated.

You can configure queue policies on MRS.

Prerequisites

- A resource pool has been added.
- The task queues are not associated with other resource pools. By default, all queues are associated with the **default** resource pool.
- You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the MRS details page, click **Tenants**.

Step 2 Click the **Resource Distribution Policies** tab.

Step 3 In **Resource Pools**, select a specified resource pool.

Available Resource Quota: indicates that all resources in each resource pool are available for queues by default.

Step 4 Locate the specified queue in the **Resource Allocation** table, and click **Modify** in the **Operation** column.

Step 5 In **Modify Resource Allocation**, configure the resource capacity policy of the task queue in the resource pool.

- **Capacity (%)**: specifies the percentage of the current tenant's computing resource usage.
- **Maximum Capacity (%)**: specifies the percentage of the current tenant's maximum computing resource usage.

Step 6 Click **OK** to save the settings.

----End

5.9.12 Clearing Configuration of a Queue

Scenario

Users can clear the configuration of a queue on MRS Manager when the queue does not need resources from a resource pool or if a resource pool needs to be disassociated from the queue. Clearing queue configurations means that the resource capacity policy of the queue is canceled.

Prerequisites

- If a queue is to be unbound from a resource pool, this resource pool cannot serve as the default resource pool of the queue. Therefore, you must first change the default resource pool of the queue to another one. For details, see **Configuring a Queue**.
- You have synchronized IAM users. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Procedure

Step 1 On the MRS details page, click **Tenants**.

Step 2 Click the **Resource Distribution Policies** tab.

Step 3 In **Resource Pools**, select a specified resource pool.

Step 4 Locate the specified queue in the **Resource Allocation** table, and click **Clear** in the **Operation** column

In the **Clear Queue Configuration** dialog box, click **OK** to clear the queue configuration in the current resource pool.

NOTE

If no resource capacity policy is configured for a queue, the clearing function is unavailable for the queue by default.

----End

5.10 Bootstrap Actions

5.10.1 Introduction to Bootstrap Actions

You can run bootstrap actions to install additional third-party software, modify the cluster running environment, and perform other customizations. Bootstrap actions can execute scripts on specified nodes before or after the first startup of cluster components. You can only manually run the third-party component installation script on the node to install a running cluster component.

If you choose to run bootstrap actions when scaling out a cluster, the bootstrap actions will be run on the newly added nodes in the same way. If auto scaling is enabled in a cluster, you can add an automation script in addition to configuring a resource plan. Then the automation script executes the corresponding script on the nodes that are scaled out or in to implement custom operations.

Your scripts are executed as user **omm** by default. You can run the **su - XXX** command in a script to switch to another user.

NOTE

Bootstrap action scripts must be executed as user **omm**. Otherwise, your cluster may become unavailable.

MRS determines the result based on the return code after the execution of the bootstrap action script. If the return code is **0**, the script is executed successfully. If the return code is not **0**, the execution fails. If a bootstrap action script fails to be executed on a node, the corresponding boot script will fail to be executed. In this case, you can set **Action upon Failure** to choose whether to continue to execute the subsequent scripts. Example 1: If you set **Action upon Failure** to **Continue** for all scripts during cluster creation, all the scripts will be executed regardless of whether they are successfully executed, and the startup process will be complete. Example 2: If a script fails to be executed and **Action upon Failure** is set to **Stop**, subsequent scripts will not be executed and cluster creation or scale-out will fail.

You can add a maximum of 18 bootstrap actions, which will be executed before or after the cluster component is started in the order you specified. The bootstrap actions performed before or after the component startup must be completed within 60 minutes. Otherwise, the cluster creation or scale-out will fail.

5.10.2 Preparing the Bootstrap Action Script

Currently, bootstrap actions support Linux shell scripts only. Script files must end with **.sh**.

Uploading the Installation Packages and Files to an OBS File System

Before compiling a script, you need to upload all required installation packages, configuration packages, and relevant files to the OBS file system in the same region. Because networks of different regions are isolated from each other, MRS VMs cannot download OBS files from other regions.

Compiling a Script for Downloading Files from the OBS File System

You can specify the file to be downloaded from OBS in the script. If you upload files to a private file system, you need to run the **hadoop fs** command to download the files. The following example shows that the **obs://yourbucket/myfile.tar.gz** file will be downloaded to the local host and decompressed to the **/your-dir** directory.

```
#!/bin/bash
source /opt/Bigdata/client/bigdata_env;hadoop fs -D fs.obs.endpoint=<obs-endpoint> -D fs.obs.access.key=<your-ak> -D fs.obs.secret.key=<your-sk> -copyToLocal obs://yourbucket/myfile.tar.gz ./
mkdir -p /<your-dir>
tar -zxvf myfile.tar.gz -C /<your-dir>
```

NOTE

- The default client installation path is /opt/Bigdata/client. Configure the path based on site requirements.
- The Hadoop client has been preinstalled on the MRS node. You can run the **hadoop fs** command to download or upload data from or to OBS.
- Obtain the obs-endpoint of each region from the administrator..
- Commands carrying authentication passwords pose security risks. Disable historical command recording before running such commands to prevent information leakage.

Uploading the Script to the OBS File System

After script compilation, upload the script to the OBS file system in the same region. At the time you specify, each node in the cluster downloads the script from OBS and executes the script as user **root**.

5.10.3 View Execution Records

You can view the execution result of the bootstrap operation on the **Bootstrap Action** page.

Viewing the Execution Result

1. Log in to the MRS console.
2. In the left navigation pane, choose **Clusters** > **Active Clusters**. Click a cluster you want to query.

   The cluster details page is displayed.
3. On the cluster details page, click the **Bootstrap Action** tab. Information about the bootstrap actions added during cluster creation is displayed.

   NOTE

   - You select **Before initial component start** or **After initial component start** in the upper right corner to query information about the related bootstrap actions.
   - The last execution result is listed here. For a newly created cluster, the records of bootstrap actions executed during cluster creation are listed. If a cluster is expanded, the records of bootstrap actions executed on the newly added nodes are listed.

Viewing Execution Logs

If you want to view the run logs of a bootstrap action, set **Action upon Failure** to **Continue** when adding the bootstrap action. And then, log in to each node to view the run logs in the **/var/log/Bootstrap** directory. If you add bootstrap actions before and after component start, you can distinguish bootstrap action logs of the two phases based on the timestamps.

You are advised to print logs in detail in the script so that you can view the detailed run result. MRS redirects the standard output and error output of the script to the log directory of the bootstrap action.

5.10.4 Adding a Bootstrap Action

Add a bootstrap action.

Procedure

Step 1 Log in to the MRS management console.

Step 2 Choose **Clusters** > **Active Clusters** and click the name of your desired cluster.

Step 3 On the page that is displayed, click the **Bootstrap Actions** tab.

Step 4 Click **Add** and set parameters as prompted.

Table 5-52 Parameters

Parameter	Description
Name	Name of a bootstrap action script The value can contain only digits, letters, spaces, hyphens (-), and underscores (_) and must not start with a space. The value can contain 1 to 64 characters. **NOTE** A name must be unique in the same cluster. You can set the same name for different clusters.
Script Path	Script path. The value can be an OBS file system path or a local VM path. ● An OBS file system path must start with **obs://** and end with **.sh**, for example, **obs://mrs-samples/***xxx***.sh**. ● A local VM path must start with a slash (/) and end with **.sh**. **NOTE** A path must be unique in the same cluster, but can be the same for different clusters.
Parameter	Bootstrap action script parameters
Execution Node	Select a type of the node where the bootstrap action script is executed.
Executed	Select the time when the bootstrap action script is executed. ● Before initial component start ● After initial component start **NOTE** You can only manually run the third-party component installation script on the node to install a running cluster component.
Action upon Failure	Whether to continue to execute subsequent scripts and create a cluster after the script fails to be executed. **NOTE** You are advised to set this parameter to **Continue** in the debugging phase so that the cluster can continue to be installed and started no matter whether the bootstrap action is successful.
Run as root	Whether to escalate the permission to user **root** If the bootstrap action requires root user operations, enable this function, or the bootstrap action may fail to execute. **NOTE** This parameter is available for MRS 3.1.5 clusters.

Step 5 Click **OK** to save the configuration.

Step 6 Click **Yes**.

----End

5.10.5 Modifying a Bootstrap Action

Scenario

Modify an existing bootstrap action on an MRS cluster.

Procedure

Step 1 Log in to the MRS management console.

Step 2 Choose **Clusters** > **Active Clusters** and click the name of your desired cluster.

Step 3 On the page that is displayed, click the **Bootstrap Actions** tab.

Step 4 In the list, select the item to be modified and click **Edit**.

Step 5 Modify the parameters as needed.

Step 6 Click **OK** to save the modification.

Step 7 Click **Yes**.

----End

5.10.6 Deleting a Bootstrap Action

Scenario

Delete a bootstrap action on an MRS cluster.

Procedure

Step 1 Log in to the MRS management console.

Step 2 Choose **Clusters** > **Active Clusters** and click the name of your desired cluster.

Step 3 On the page that is displayed, click the **Bootstrap Actions** tab.

Step 4 In the list, select the item to be deleted and click **Delete**.

Step 5 Click **OK**.

----End

6 Using an MRS Client

6.1 Installing a Client

Scenario

Install clients of all services (excluding Flume) in an MRS cluster. For details about how to install the Flume client, see "Component Operation Guide" > "Using Flume" > "Installing the Flume Client".

You can install the clients on a node in or outside the cluster.

After modifying the server configuration of a cluster component, reinstall the component client to ensure the server and the client both run the same version to provide services properly.

Prerequisites

- If the node where the client is to be installed is outside the cluster, the node must be able to communicate with the nodes in the cluster. Otherwise, client installation will fail.
- The node where the client is to be installed must have the NTP service enabled and synchronized time with the server. Otherwise, client installation will fail.
- You install the client as user **root** or any OS user. The user must have the operation permission on the client file storage directory and installation directory. The permission on the two directories is **755**.

  This section uses the OS user **user_client** as an example to describe how to install the client in the **/opt/hadoopclient** directory.
- When you install the client as a user other than **omm** or **root**, and the **/var/tmp/patch** directory already exists, you have changed the permission for the directory to **777** and changed the permission for the logs in the directory to **666**.

Installing a Client on a Node Inside a Cluster

Step 1 Obtain the client software package.

Log in to FusionInsight Manager by referring to **Accessing FusionInsight Manager**. On the **Cluster** > **Dashboard** page, click the more sign (...) and select **Download Client**. In the **Download Cluster Client** dialog box displayed, configure parameters and click **OK**.

NOTE

- The client software package downloaded from the FusionInsight Manager homepage contains the clients of all services (excluding Flume) in the cluster. To download the client of a single service, choose **Cluster** > **Services** > *Service name*, click **More**, and select **Download Client**.
- For MRS 3.3.0 or later, click **Download Client** on the home page.

Table 6-1 Client download parameters

Parameter	Description	Example Value
Select Client Type	• **Complete Client**: contains the complete client software package and configuration files, which applies to non-development task scenarios. • **Configuration Files Only**: downloads only client configuration files in the scenario where the administrator modifies the server configuration on FusionInsight Manager after the complete client is downloaded and installed in an application development task, and developers need to update client configuration files.	Complete Client
Select Platform Type	**The client type must match the architecture of the node where the client is to be installed. Otherwise, the installation fails. For clusters of the LTS version, only the client software package whose type is the same as that of FusionInsight Manager can be downloaded.** • **x86_64**: indicates the client software package that can be deployed on a x86 platform. • **aarch64**: indicates the client software package that can be deployed on a TaiShan server.	x86_64

Parameter	Description	Example Value
Save to Path	The path for storing the client software package on the active OMS node • Select **Save to Path**: Customize the path for storing the client software package on the active OMS node. User **omm** must have the read, write, and execute permissions on the path. If the path is not changed, the client file generated is saved in the **/tmp/FusionInsight-Client** directory on the active OMS node in the cluster by default. • Not to select **Save to Path**: The generated client file is automatically downloaded and saved to the local host. Before installing the client, you need to upload the file to a specified directory on the target node.	Select **Save to Path**

Step 2 Copy the client software package to a specified directory on the node where the client is to be installed.

By default, the client software package is stored on the active OMS node in the cluster. To install the client on other nodes in the cluster, log in to the active OMS node as user **omm** and run the following command to copy the software package to the specified node. Otherwise, skip this step.

For example, copy the software package to the **/tmp/clienttemp** directory.

scp -p */tmp/FusionInsight-Client/***FusionInsight_Cluster_1_Services_Client.tar** *IP address of the node where the client is to be installed:/tmp/clienttemp*

Step 3 Log in to the target node as a user, for example, **user_client**.

NOTE

You can install the client as user **root** or any other OS user. The user must have the operation permission on the client file storage directory and installation directory. The permission on the two directories is **755**.

Step 4 Decompress the client software package.

Go to the directory where the package is stored, for example, **/tmp/clienttemp**.

cd /tmp/clienttemp

Run the following commands to decompress the package and obtain **FusionInsight_Cluster_1_Services_ClientConfig.tar**:

tar -xvf FusionInsight_Cluster_1_Services_Client.tar

Run the following command to decompress **FusionInsight_Cluster_1_Services_ClientConfig.tar**:

tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar

Step 5 Go to the package directory and run the following command to install the client to a specified directory:

cd FusionInsight_Cluster_1_Services_ClientConfig

./install.sh *Client installation directory*

For example, run the **./install.sh /opt/hadoopclient** command to install the client and wait until the installation is complete.

```
...
The component client is installed successfully
```

NOTE

- **If there is no specified client installation directory, it will be automatically created. If you specify an existing directory, it must be empty, and the path cannot contain spaces. The value can contain only uppercase letters, lowercase letters, digits, and underscores (_).**
- You need to manually delete the client installation directory when uninstalling a client.
- To ensure that the installed client can be used only by the installation user, add the **-o** parameter during the installation. For example, run the **./install.sh /opt/hadoopclient -o** command to install the client.

Step 6 Use the client by referring to "Using the client of Each Component".

----End

Installing a Client on a Node Outside a Cluster

Step 1 Create an ECS that meets the following requirements:

- A Linux ECS has been prepared. For details about the supported OS of the ECS, see **Table 6-2**.

  Table 6-2 Reference list

CPU Architecture	OS	Supported Version
x86 computing	EulerOS	EulerOS 2.5
	SUSE	SUSE Linux Enterprise Server 12 SP4 (SUSE 12.4)
	Red Hat	Red Hat-7.5-x86_64 (Red Hat 7.5)
	CentOS	CentOS 7.6
Kunpeng computing (Arm)	EulerOS	EulerOS 2.8
	CentOS	CentOS 7.6

  In addition, sufficient disk space is allocated for the ECS, for example, 40 GB.
- The ECS and the MRS cluster are in the same VPC.

- The security group of the ECS must be the same as that of the master node in the MRS cluster.
- The NTP service has been installed on the ECS OS and is running properly.

  If the NTP service is not installed, run the **yum install ntp -y** command to install it when the **yum** source is configured.
- A user can log in to the Linux ECS using the password (in SSH mode).
- All ports in the inbound direction of the MRS cluster security group are open to the client node.

Step 2 Perform NTP time synchronization to synchronize the time of nodes outside the cluster with the time of the MRS cluster.

1. Run the **vi /etc/ntp.conf** command to edit the NTP client configuration file, add the IP addresses of the master node in the MRS cluster, and comment out the IP address of other servers.

   server *master1_ip* prefer
   server *master2_ip*

   Figure 6-1 Adding the master node IP addresses

   ```
   # For more information about this file, see the man pages
   # ntp.conf(5), ntp_acc(5), ntp_auth(5), ntp_clock(5), ntp_misc(5), ntp_mon(5).

   driftfile /var/lib/ntp/drift

   # Permit time synchronization with our time source, but do not
   # permit the source to query or modify the service on this system.
   restrict default nomodify notrap nopeer noquery

   # Permit all access over the loopback interface.  This could
   # be tightened as well, but to do so would effect some of
   # the administrative functions.
   restrict 127.0.0.1
   restrict ::1

   # Hosts on local network are less restricted.
   #restrict 192.168.1.0 mask 255.255.255.0 nomodify notrap

   # Use public servers from the pool.ntp.org project.
   # Please consider joining the pool (http://www.pool.ntp.org/join.html).
   #server 0.centos.pool.ntp.org iburst
   #server 1.centos.pool.ntp.org iburst
   #server 2.centos.pool.ntp.org iburst
   #server 3.centos.pool.ntp.org iburst
   #
   server 10.9.2.38 prefer
   server 10.9.2.39
   #broadcast 192.168.1.255 autokey        # broadcast server
   #broadcastclient                        # broadcast client
   #broadcast                  autokey     # multicast server
   #multicastclient                        # multicast client
   #manycastserver                         # manycast server
   #manycastclient                 autokey # manycast client

   # Enable public key cryptography.
   #crypto
   ```

2. Run the **service ntpd stop** command to stop the NTP service.
3. Run the following command to manually synchronize the time:

   /usr/sbin/ntpdate *192.168.10.8*

   NOTE

   192.168.10.8 indicates the IP address of the active Master node.

4. Run the **service ntpd start** or **systemctl restart ntpd** command to start the NTP service.
5. Run the **ntpstat** command to check the time synchronization result.

Step 3 Obtain the client software package.

Log in to FusionInsight Manager by referring to **Accessing FusionInsight Manager**. On the **Cluster** > **Dashboard** page, click the more sign (...) and select **Download Client**. In the **Download Cluster Client** dialog box displayed, configure parameters and click **OK**.

NOTE

- The client software package downloaded from the FusionInsight Manager homepage contains the clients of all services (excluding Flume) in the cluster. To download the client of a single service, choose **Cluster** > **Services** > *Service name*, click **More**, and select **Download Client**.
- For MRS 3.3.0 or later, click **Download Client** on the home page.

Table 6-3 Client download parameters

Parameter	Description	Example Value
Select Client Type	• **Complete Client**: contains the complete client software package and configuration files, which applies to non-development task scenarios. • **Configuration Files Only**: downloads only client configuration files in the scenario where the administrator modifies the server configuration on FusionInsight Manager after the complete client is downloaded and installed in an application development task, and developers need to update client configuration files.	Complete Client
Select Platform Type	**The client type must match the architecture of the node where the client is to be installed. Otherwise, the installation fails. For clusters of the LTS version, only the client software package whose type is the same as that of FusionInsight Manager can be downloaded.** • **x86_64**: indicates the client software package that can be deployed on a x86 platform. • **aarch64**: indicates the client software package that can be deployed on a TaiShan server.	x86_64

Parameter	Description	Example Value
Save to Path	The path for storing the client software package on the active OMS node • Select **Save to Path**: Customize the path for storing the client software package on the active OMS node. User **omm** must have the read, write, and execute permissions on the path. If the path is not changed, the client file generated is saved in the **/tmp/FusionInsight-Client** directory on the active OMS node in the cluster by default. • Not to select **Save to Path**: The generated client file is automatically downloaded and saved to the local host. Before installing the client, you need to upload the file to a specified directory on the target node.	Select **Save to Path**

Step 4 Copy the client software package to a specified directory on the node where the client is to be installed.

The generated client software package is stored on the active OMS node of the cluster by default. You need to log in to the active OMS node as user **omm** and run the following command to copy the software package to a specified ECS:

For example, copy the software package to the **/tmp/clienttemp** directory.

scp -p */tmp/FusionInsight-Client/***FusionInsight_Cluster_1_Services_Client.tar** *IP address of the node where the client is to be installed:/tmp/clienttemp*

Step 5 Log in to the target node as a user, for example, **user_client**.

NOTE

You can install the client as user **root** or any other OS user. The user must have the operation permission on the client file storage directory and installation directory. The permission on the two directories is **755**.

Step 6 Decompress the client software package.

Go to the directory where the package is stored, for example, **/tmp/clienttemp**.

cd /tmp/clienttemp

Run the following commands to decompress the package and obtain **FusionInsight_Cluster_1_Services_ClientConfig.tar**:

tar -xvf FusionInsight_Cluster_1_Services_Client.tar

Run the following command to decompress **FusionInsight_Cluster_1_Services_ClientConfig.tar**:

tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar

Step 7 Check the network connection of the client.

1. Ensure that the host where the client is installed can communicate with the hosts listed in the **hosts** file stored in the directory containing the decompressed package, for example, **/tmp/FusionInsight_Cluster_1_Services_ClientConfig/hosts**.
2. If the host where the client is installed is not a host in the cluster, you need to set the mapping between the host name and the service plane IP address for each cluster node in **/etc/hosts**, as user **root**. Each host name uniquely maps an IP address. You can perform the following steps to import the domain name mapping of the cluster to the **hosts** file:
   a. Switch to user **root** or a user who has the permission to modify the **hosts** file.

      su - root

   b. Go to the directory where the client package is decompressed.

      cd /tmp/clienttemp/FusionInsight_Cluster_1_Services_ClientConfig

   c. Run the **cat realm.ini >> /etc/hosts** command to import the domain name mapping to the **hosts** file.

NOTE

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- If Spark tasks are executed in yarn-client mode, add the **spark.driver.host** parameter to the file *Client installation directory*/**Spark/spark/conf/spark-defaults.conf** and set the parameter to the client IP address.
- If the yarn-client mode is used, you need to configure the mapping between the IP address and host name of the client in the **hosts** file on the active and standby Yarn nodes (ResourceManager nodes in the cluster) to make sure that the Spark web UI is properly displayed.

Step 8 Log in to the node where the client is to be installed as user **user_client**, go to the client software package directory, and run the following command to install the client to a specified directory:

cd /tmp/clienttemp/FusionInsight_Cluster_1_Services_ClientConfig

./install.sh *Client installation directory*

For example, run the **./install.sh /opt/hadoopclient** command to install the client and wait until the installation is complete.

```
...
The component client is installed successfully
```

NOTE

- **If there is no specified client installation directory, it will be automatically created. If you specify an existing directory, it must be empty, and the path cannot contain spaces. The value can contain only uppercase letters, lowercase letters, digits, and underscores (_).**
- You need to manually delete the client installation directory when uninstalling a client.
- To ensure that the installed client can be used only by the installation user, add the **-o** parameter during the installation. For example, run the **./install.sh /opt/hadoopclient -o** command to install the client.

Step 9 Use the client by referring to "Using the client of Each Component".

----End

6.2 Updating a Client

A cluster provides a client for you to connect to a server, view task results, or manage data. If you modify service configuration parameters on Manager and restart the service, you need to download and install the client again or use the configuration file to update the client.

Updating the Client Configuration

Method 1:

Step 1 Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager**. Click the name of the cluster to be operated in the **Cluster** drop-down list.

Step 2 Choose **More** > **Download Client** > **Configuration Files Only**.

The generated compressed file contains the configuration files of all services.

Step 3 Determine whether to generate a configuration file on the cluster node.

- If yes, select **Save to Path**, and click **OK** to generate the client file. By default, the client file is generated in **/tmp/FusionInsight-Client** on the active management node. You can also store the client file in other directories, and user **omm** has the read, write, and execute permissions on the directories. Then go to **Step 4**.
- If no, click **OK**, specify a local save path, and download the complete client. Wait until the download is complete and go to **Step 4**.

Step 4 Use WinSCP to save the compressed file to the client installation directory, for example, **/opt/hadoopclient**, as the client installation user.

Step 5 Decompress the software package.

Run the following commands to go to the directory where the client is installed, and decompress the file to a local directory. For example, the downloaded client file is **FusionInsight_Cluster_1_Services_Client.tar**.

cd /opt/hadoopclient

tar -xvf FusionInsight_Cluster_1_Services_Client.tar

Step 6 Verify the software package.

Run the following command to verify the decompressed file and check whether the command output is consistent with the information in the **sha256** file.

sha256sum -c FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles.tar.sha256

```
FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles.tar: OK
```

Step 7 Decompress the package to obtain the configuration file.

tar -xvf FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles.tar

Step 8 Run the following command in the client installation directory to update the client using the configuration file:

sh refreshConfig.sh *Client installation directory Directory where the configuration file is located*

For example, run the following command:

sh refreshConfig.sh /opt/hadoopclient /opt/hadoopclient/FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles

If the following information is displayed, the configurations have been updated successfully.

```
Succeed to refresh components client config.
```

----End

Method 2:

Step 1 Log in to the client installation node as user **root**.

Step 2 Go to the client installation directory, for example, **/opt/hadoopclient** and run the following commands to update the configuration file:

cd /opt/hadoopclient

sh autoRefreshConfig.sh

Step 3 Enter the username and password of the FusionInsight Manager administrator and the floating IP address of OMS.

NOTE

To obtain the floating IP address of OMS, log in to the Master2 node remotely, and run the **ifconfig** command. In the command output, **eth0:wsom** indicates the floating IP address of OMS. Record the value of **inet**. If the floating IP address of OMS cannot be queried on the Master2 node, switch to the Master1 node to query and record the floating IP address. If there is only one Master node, query and record the IP address on the Master node.

Step 4 Enter the names of the components whose configuration needs to be updated. Use commas (,) to separate the component names. Press **Enter** to update the configurations of all components if necessary.

If the following information is displayed, the configurations have been updated successfully.

```
Succeed to refresh components client config.
```

----End

6.3 Using the Client of Each Component

6.3.1 Using a ClickHouse Client

ClickHouse is a column-based database oriented to online analysis and processing. It supports SQL query and provides good query performance. The aggregation analysis and query performance based on large and wide tables is excellent, which is one order of magnitude faster than other analytical databases.

Prerequisites

The client has been installed in a directory, for example, **/opt/client**. The client directory in the following operations is only an example. Change it to the actual installation directory. Before using the client, download and update the client configuration file, and ensure that the active management node of Manager is available.

Procedure

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If Kerberos authentication has been enabled for the current cluster, run the following command to authenticate the user. The current user must have the permission to create ClickHouse tables. If Kerberos authentication is disabled for the current cluster, skip this step.

For an MRS 3.1.0 cluster, run the **export CLICKHOUSE_SECURITY_ENABLED=true** command first.

kinit *Component service user*

Example: **kinit clickhouseuser**

Step 5 Run the client command of the ClickHouse component.

Run the **clickhouse -h** command to view the command help of ClickHouse.

The command output is as follows:

```
Use one of the following commands:
clickhouse local [args]
clickhouse client [args]
clickhouse benchmark [args]
clickhouse server [args]
clickhouse performance-test [args]
clickhouse extract-from-config [args]
clickhouse compressor [args]
clickhouse format [args]
clickhouse copier [args]
clickhouse obfuscator [args]
...
```

For MRS 3.1.0, run the **clickhouse client** command to connect to the ClickHouse server.

- Command for using a non-SSL mode to log in to a ClickHouse cluster with Kerberos authentication disabled

  clickhouse client --host *IP address of the ClickHouse instance* **--port 9000 --user** *Username* **--password**

  Enter the user password.

- Using SSL for login when Kerberos authentication is enabled for the current cluster:

There are no default users in clusters with Kerberos authentication enabled. You must create a user on FusionInsight Manager.

After the user authentication is successful, you do not need to carry the **--user** and **--password** parameters when logging in to the client as the authenticated user.

clickhouse client --host *IP address of the ClickHouse instance* **--port 9440 --secure**

For MRS 3.1.2 or later, run the **clickhouse client** command to connect to the ClickHouse server.

- Command for using a non-SSL mode to log in to a ClickHouse cluster with Kerberos authentication disabled

  clickhouse client --host *IP address of the ClickHouse instance* **--port 9000 --user** *Username* **--password**

  Enter the user password.

- Using SSL for login when Kerberos authentication is enabled for the current cluster:

  There are no default users in clusters with Kerberos authentication enabled. You must create a user on FusionInsight Manager.

  clickhouse client --host *IP address of the ClickHouse instance* **--port 9440 --user** *Username* **--password --secure**

  Enter the user password.

Run the **quit;** command to exit the ClickHouse server connection.

Table 6-4 describes related parameters.

Table 6-4 Parameters of the **clickhouse client** command

Parameter	Description
--host	Host name of the server. The default value is **localhost**. You can use the host name or IP address of the node where the ClickHouse instance is located. **NOTE** You can log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse** > **Instance** to obtain the service IP address of the ClickHouseServer instance.
--port	Port for connection. • If the SSL security connection is used, the default port number is **9440**, the parameter **--secure** must be carried. For details about the port number, search for the **tcp_port_secure** parameter in the ClickHouseServer instance configuration. • If non-SSL security connection is used, the default port number is **9000**, the parameter **--secure** does not need to be carried. For details about the port number, search for the **tcp_port** parameter in the ClickHouseServer instance configuration.

Parameter	Description
--user	Username. You can create a user on FusionInsight Manager and bind roles to it. ● If Kerberos authentication has been enabled for the current cluster (the cluster is in security mode) and the user authentication is successful, you do not need to carry the **--user** and **--password** parameters during your login to the client as the authenticated user. You must create a user with this name on Manager because there is no default user in the Kerberos cluster scenario. ● If Kerberos authentication has not been enabled for the current cluster (the cluster is in normal mode), you cannot use the ClickHouse user created on FusionInsight Manager if you need to specify the username and password when you log in to the client. You need to execute the **create user SQL** statement on the client to create a ClickHouse user. If you do not need to specify the username and password during your login to the client, the default user is used by default.
--password	Password. The default password is an empty string. This parameter is used together with the **--user** parameter. You can set a password when creating a user on Manager.
--query	Query to process when using non-interactive mode.
--database	Current default database. The default value is **default**, which is the default configuration on the server.
--multiline	If this parameter is specified, multiline queries are allowed. (**Enter** only indicates line feed and does not indicate that the query statement is complete.)
--multiquery	If this parameter is specified, multiple queries separated with semicolons (;) can be processed. This parameter is valid only in non-interactive mode.
--format	Specified default format used to output the result.
--vertical	If this parameter is specified, the result is output in vertical format by default. In this format, each value is printed on a separate line, which helps to display a wide table.
--time	If this parameter is specified, the query execution time is printed to **stderr** in non-interactive mode.
--stacktrace	If this parameter is specified, stack trace information will be printed when an exception occurs.
--config-file	Name of the configuration file.
--secure	If this parameter is specified, the server will be connected in SSL mode.

Parameter	Description
--history_file	Path of files that record command history.
--param_<name>	Query with parameters. Pass values from the client to the server.

----End

6.3.2 Using a Flink Client

This section describes how to use Flink to run wordcount jobs.

Prerequisites

- Flink has been installed in an MRS cluster.
- The cluster runs properly and the client has been correctly installed, for example, in the **/opt/hadoopclient** directory. The client directory in the following operations is only an example. Change it to the actual installation directory.

Using the Flink Client-

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/hadoopclient

Step 3 Run the following command to initialize environment variables:

source /opt/hadoopclient/bigdata_env

Step 4 Perform the following operations if Kerberos authentication is enabled for the cluster. Otherwise, skip these operations.

1. Prepare a user for submitting Flink jobs.

   Log in to FusionInsight Manager and choose **System** > **Permission** > **Role**. Click **Create Role** and configure **Role Name** and **Description**. In **Configure Resource Permission**, choose *Name of the desired cluster* > **Flink** and select **FlinkServer Admin Privilege**. Then click **OK**.

   Choose **System** > **Permission** > **User** and click **Create User**. Configure **Username**, set **User Type** to **Human-Machine**, configure **Password** and **Confirm Passowrd**, click **Add** next to **User Group** to add the **hadoop**, **yarnviewgroup**, and **hadooppmanager** user groups as needed, click **Add** next to **Role** to add the **System_administrator**, **default**, and the created role, and click **OK**. (If you create a Flink job user for the first time, log in to FusionInsight Manager as the user and change the password.)

2. Log in to Manager and download the authentication credential.

   Log in to FusionInsight Manager. Choose **System** > **Permission** > **User**. In the **Operation** column of the created user, click **More** and select **Download Authentication Credential**.

3. Decompress the downloaded authentication credential package and copy the obtained file to a directory on the client node, for example, **/opt/hadoopclient/Flink/flink/conf**. If the client is installed on a node outside the cluster, copy the obtained file to the **/etc/** directory on this node.
4. Add the service IP address of the node where the client is installed and IP addresses of all master nodes to the **jobmanager.web.access-control-allow-origin** and **jobmanager.web.allow-access-address** configuration items in the **/opt/hadoopclient/Flink/flink/conf/flink-conf.yaml** file. Use commas (,) to separate the IP addresses.

   ```
   jobmanager.web.access-control-allow-origin: xx.xx.xxx.xxx,xx.xx.xxx.xxx,xx.xx.xxx.xxx
   jobmanager.web.allow-access-address: xx.xx.xxx.xxx,xx.xx.xxx.xxx,xx.xx.xxx.xxx
   ```

   NOTE

   To obtain the service IP address of the node where the client is installed, perform the following operations:

   - Node inside the cluster:

     In the navigation tree of the MRS management console, choose **Clusters > Active Clusters**, select a cluster, and click its name to switch to the cluster details page.

     On the **Nodes** tab page, view the IP address of the node where the client is installed.
   - Node outside the cluster: IP address of the ECS where the client is installed.
5. Configure security authentication by adding the **keytab** path and username in the **/opt/hadoopclient/Flink/flink/conf/flink-conf.yaml** configuration file.

   security.kerberos.login.keytab: *<user.keytab file path>*
   security.kerberos.login.principal: *<Username>*

   Example:

   ```
   security.kerberos.login.keytab: /opt/hadoopclient/Flink/flink/conf/user.keytab
   security.kerberos.login.principal: test
   ```
6. In the **bin** directory of the Flink client, run the following command to perform security hardening and configure a password used for submitting jobs:

   cd /opt/hadoopclient/Flink/flink/bin

   sh generate_keystore.sh

   The script automatically replaces the SSL value in the **/opt/hadoopclient/Flink/flink/conf/flink-conf.yaml** file.

NOTE

After authentication and encryption, the **flink.keystore** and **flink.truststore** files are generated in the **conf** directory on the Flink client and the following configuration items are set to the default values in the **flink-conf.yaml** file:

- Set **security.ssl.keystore** to the absolute path of the **flink.keystore** file.
- Set **security.ssl.truststore** to the absolute path of the **flink.truststore** file.
- Set **security.cookie** to a random password automatically generated by the **generate_keystore.sh** script.
- By default, **security.ssl.encrypt.enabled** is set to **false** in the **flink-conf.yaml** file by default. The **generate_keystore.sh** script sets **security.ssl.key-password**, **security.ssl.keystore-password**, and **security.ssl.truststore-password** to the password entered when the **generate_keystore.sh** script is called. There can be security risks if a configuration file contains the authentication password. You are advised to delete the configuration file or use other secure methods to keep the password.
- For MRS 3.*x* or later, if ciphertext is required and **security.ssl.encrypt.enabled** is set to **true** in the **flink-conf.yaml** file, the **generate_keystore.sh** script does not set **security.ssl.key-password**, **security.ssl.keystore-password**, and **security.ssl.truststore-password**. To obtain the values, use the Manager plaintext encryption API by running **curl -k -i -u** *Username*:*Password* **-X POST -HContent-type:application/json -d '{"plainText":"***Password***"}' 'https://***x.x.x.x***:28443/web/api/v2/tools/encrypt'**.

  In the preceding command, *Username*:*Password* indicates the user name and password for logging in to the system. The password of **"plainText"** indicates the one used to call the **generate_keystore.sh** script. *x.x.x.x* indicates the floating IP address of Manager. There can be security risks if a command contains the authentication password. You are advised to disable the command recording function (history) before running the command.

7. Configure paths for the client to access the **flink.keystore** and **flink.truststore** files.
   - Relative path (recommended):

     Perform the following steps to set the file path of **flink.keystore** and **flink.truststore** to the relative path and ensure that the directory where the Flink client command is executed can directly access the relative paths.

     i. Create a directory, for example, **ssl**, in **/opt/hadoopclient/Flink/flink/conf/**.

     cd /opt/hadoopclient/Flink/flink/conf/

     mkdir ssl

     ii. Move the **flink.keystore** and **flink.truststore** files to the **/opt/hadoopclient/Flink/flink/conf/ssl/** directory.

     mv flink.keystore ssl/

     mv flink.truststore ssl/

     iii. Change the values of the following parameters to relative paths in the **flink-conf.yaml** file:

     ```
     security.ssl.keystore: ssl/flink.keystore
     security.ssl.truststore: ssl/flink.truststore
     ```

   - Absolute path:

     After the **generate_keystore.sh** script is executed, the file path of **flink.keystore** and **flink.truststore** is automatically set to the absolute path **/opt/hadoopclient/Flink/flink/conf/** in the **flink-conf.yaml** file. In

this case, you need to move the **flink.keystore** and **flink.truststore** files from the **conf** directory to this absolute path on the Flink client and YARN nodes.

Step 5 Run a wordcount job.

NOTICE

When a user submits or runs a job in Flink, the user must have the following permissions based on whether Ranger authentication is enabled for related services (such as HDFS and Kafka):

- If Ranger authentication is enabled, the current user must belong to the **hadoop** group or the user has been granted the **/flink** read and write permissions in Ranger.
- If Ranger authentication is disabled, the current user must belong to the **hadoop** group.

- For a normal cluster (Kerberos authentication disabled), you can submit jobs in either of the following ways:
  - Run the following commands to start a session and submit a job in the session:

    yarn-session.sh -nm "*session-name***" -d**

    flink run /opt/hadoopclient/Flink/flink/examples/streaming/WordCount.jar
  - Run the following command to submit a single job on Yarn:

    flink run -m yarn-cluster /opt/hadoopclient/Flink/flink/examples/streaming/WordCount.jar
- For a security cluster (Kerberos authentication enabled), you can submit jobs in either of the following ways based on the paths of the **flink.keystore** and **flink.truststore** files:
  - If the **flink.keystore** and **flink.truststore** files are stored in the relative path:
    - Run the following command in the directory at the same level as **ssl** to start the session and submit the job in the session:

      ssl is a relative path. For example, if **ssl** is in **opt/hadoopclient/Flink/flink/conf/**, run the command in the **opt/hadoopclient/Flink/flink/conf/** directory.

      cd /opt/hadoopclient/Flink/flink/conf

      yarn-session.sh -t ssl/ -nm "*session-name***" -d**

      flink run /opt/hadoopclient/Flink/flink/examples/streaming/WordCount.jar
    - Run the following command to submit a single job on Yarn:

      cd /opt/hadoopclient/Flink/flink/conf

      flink run -m yarn-cluster -yt ssl/ /opt/hadoopclient/Flink/flink/examples/streaming/WordCount.jar

  - If the **flink.keystore** and **flink.truststore** files are stored in the absolute path:
    - Run the following commands to start a session and submit a job in the session:

      cd /opt/hadoopclient/Flink/flink/conf

      yarn-session.sh -nm "*session-name***" -d**

      flink run /opt/hadoopclient/Flink/flink/examples/streaming/WordCount.jar

    - Run the following command to submit a single job on Yarn:

      flink run -m yarn-cluster /opt/hadoopclient/Flink/flink/examples/streaming/WordCount.jar

Step 6 After the job has been successfully submitted, the following information is displayed on the client:

Figure 6-2 Job submitted successfully on Yarn

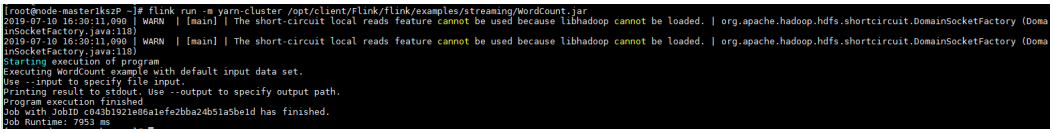


Figure 6-3 Session started successfully

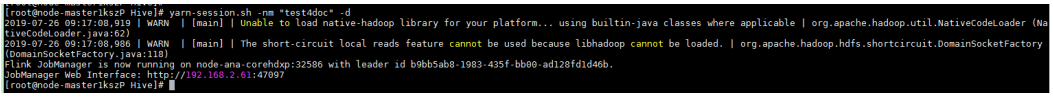

Figure 6-4 Job submitted successfully in the session

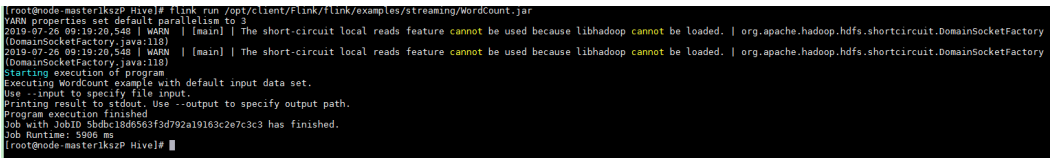
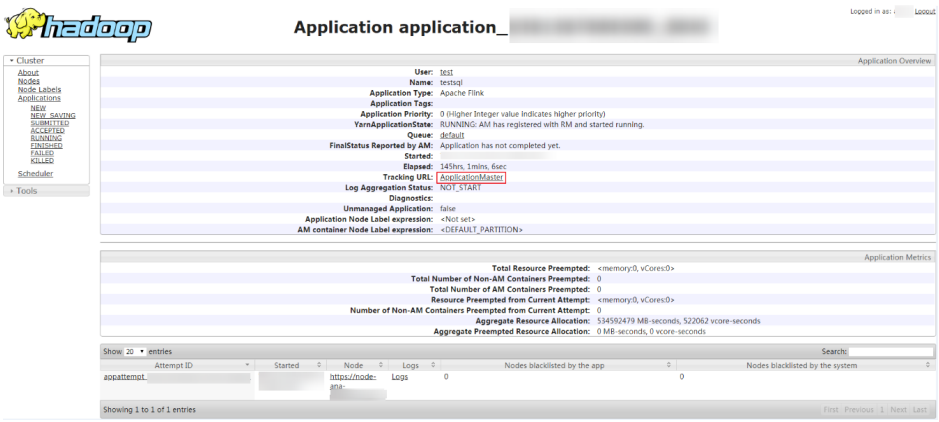


Step 7 Go to the native Yarn service page, find the application of the job, and click the application name to go to the job details page.

- If the job is not completed, click **Tracking URL** to go to the native Flink page and view the job running information.
- If the job submitted in a session has been completed, you can click **Tracking URL** to log in to the native Flink service page to view job information.

Figure 6-5 application



----End

6.3.3 Using a Flume Client

Scenario

You can use Flume to import collected log information to Kafka.

Prerequisites

- A streaming cluster that contains components such as Flume and Kafka and has Kerberos authentication enabled has been created.
- The streaming cluster can properly communicate with the node where logs are generated.

Using the Flume Client

NOTE

You do not need to perform **Step 2** to **Step 6** for a normal cluster.

Step 1 Install the Flume client.

Install the Flume client in a directory, for example, **/opt/Flumeclient**, on the node where logs are generated by referring to **Installing the Flume Client**. The Flume client installation directories in the following steps are only examples. Change them to the actual installation directories.

Step 2 Copy the configuration file of the authentication server from the Master1 node to the *Flume client installation directory*/**fusioninsight-flume-***Flume component version number*/**conf** directory on the node where the Flume client is installed.

The full file path is **${BIGDATA_HOME}/FusionInsight_BASE_***XXX*/**1_***X*_KerberosClient/etc/kdc.conf**. In the preceding path, **XXX** indicates the product version number. **X** indicates a random number. Replace them based on site requirements. The file must be saved by the user who installs the Flume client, for example, user **root**.

Step 3 Check the service IP address of any node where the Flume role is deployed.

Log in to FusionInsight Manager, click **Cluster**, click **Services**, and click Flume. On the displayed page, click **Instance**. Check the service IP address of any node where the Flume role is deployed.

NOTE

If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Step 4 Copy the user authentication file from this node to the *Flume client installation directory*/**fusioninsight-flume-Flume component version number/conf** directory on the Flume client node.

The full file path is **${BIGDATA_HOME}/FusionInsight_Porter_***XXX*/**install/FusionInsight-Flume-***Flume component version number*/**flume/conf/flume.keytab**.

In the preceding paths, **XXX** indicates the product version number. Change it based on the site requirements. The file must be saved by the user who installs the Flume client, for example, user **root**.

Step 5 Copy the **jaas.conf** file from this node to the **conf** directory on the Flume client node.

The full file path is **${BIGDATA_HOME}/FusionInsight_Current/1_***X*_**Flume/etc/jaas.conf**.

In the preceding path, **X** indicates a random number. Change it based on the site requirements. The file must be saved by the user who installs the Flume client, for example, user **root**.

Step 6 Log in to the Flume client node and go to the client installation directory. Run the following command to modify the file:

vi conf/jaas.conf

Change the full path of the user authentication file defined by **keyTab** to the **Flume client installation directory/fusioninsight-flume-*Flume component version number*/conf** saved in **Step 4**, and save the modification and exit.

Step 7 Run the following command to modify the **flume-env.sh** configuration file of the Flume client:

vi *Flume client installation directory*/**fusioninsight-flume-***Flume component version number*/**conf/flume-env.sh**

Add the following information after **-XX:+UseCMSCompactAtFullCollection**:

```
-Djava.security.krb5.conf=Flume client installation directory/fusioninsight-flume-1.9.0/conf/kdc.conf -Djava.security.auth.login.config=Flume client installation directory/fusioninsight-flume-1.9.0/conf/jaas.conf -Dzookeeper.request.timeout=120000
```

Example: **"-XX:+UseCMSCompactAtFullCollection -Djava.security.krb5.conf=/opt/FlumeClient/fusioninsight-flume-***Flume component version number*/**conf/kdc.conf -Djava.security.auth.login.config=/opt/FlumeClient/fusioninsight-flume-***Flume component version number*/**conf/jaas.conf -Dzookeeper.request.timeout=120000"**

Change *Flume client installation directory* to the actual installation directory. Then save and exit.

Step 8 Run the following command to restart the Flume client:

cd *Flume client installation directory*/**fusioninsight-flume-**_Flume component version number_/**bin**

./flume-manage.sh restart

Example:

cd /opt/FlumeClient/fusioninsight-flume-_Flume component version number_/**bin**

./flume-manage.sh restart

Step 9 Configure jobs based on actual service scenarios.

- Some parameters, for MRS 3.*x* or later, can be configured on Manager.
- Set the parameters in the **properties.properties** file. The following uses SpoolDir Source+File Channel+Kafka Sink as an example.

  Run the following command on the node where the Flume client is installed. Configure and save jobs in the Flume client configuration file **properties.properties** based on actual service requirements.

  vi *Flume client installation directory*/**fusioninsight-flume-**_Flume component version number_/**conf/properties.properties**

```
################################################################################
####################
client.sources = static_log_source
client.channels = static_log_channel
client.sinks = kafka_sink
################################################################################
####################
#LOG_TO_HDFS_ONLINE_1

client.sources.static_log_source.type = spooldir
client.sources.static_log_source.spoolDir = Monitoring directory
client.sources.static_log_source.fileSuffix = .COMPLETED
client.sources.static_log_source.ignorePattern = ^$
client.sources.static_log_source.trackerDir = Metadata storage path during transmission
client.sources.static_log_source.maxBlobLength = 16384
client.sources.static_log_source.batchSize = 51200
client.sources.static_log_source.inputCharset = UTF-8
client.sources.static_log_source.deserializer = LINE
client.sources.static_log_source.selector.type = replicating
client.sources.static_log_source.fileHeaderKey = file
client.sources.static_log_source.fileHeader = false
client.sources.static_log_source.basenameHeader = true
client.sources.static_log_source.basenameHeaderKey = basename
client.sources.static_log_source.deletePolicy = never

client.channels.static_log_channel.type = file
client.channels.static_log_channel.dataDirs = Data cache path. Multiple paths, separated by commas (,), can be configured to improve performance.
client.channels.static_log_channel.checkpointDir = Checkpoint storage path
client.channels.static_log_channel.maxFileSize = 2146435071
client.channels.static_log_channel.capacity = 1000000
client.channels.static_log_channel.transactionCapacity = 612000
client.channels.static_log_channel.minimumRequiredSpace = 524288000

client.sinks.kafka_sink.type = org.apache.flume.sink.kafka.KafkaSink
client.sinks.kafka_sink.kafka.topic = Topic to which data is written, for example, flume_test
client.sinks.kafka_sink.kafka.bootstrap.servers = XXX.XXX.XXX.XXX:Kafka port number,XXX.XXX.XXX.XXX:Kafka port number,XXX.XXX.XXX.XXX:Kafka port number
```

```
client.sinks.kafka_sink.flumeBatchSize = 1000
client.sinks.kafka_sink.kafka.producer.type = sync
client.sinks.kafka_sink.kafka.security.protocol = SASL_PLAINTEXT
client.sinks.kafka_sink.kafka.kerberos.domain.name = Kafka domain name. This parameter is mandatory for a security cluster, for example, hadoop.xxx.com.
client.sinks.kafka_sink.requiredAcks = 0

client.sources.static_log_source.channels = static_log_channel
client.sinks.kafka_sink.channel = static_log_channel
```

NOTE

- **client.sinks.kafka_sink.kafka.topic**: Topic to which data is written. If the topic does not exist in Kafka, it is automatically created by default.
- **client.sinks.kafka_sink.kafka.bootstrap.servers**: List of Kafka Brokers, which are separated by commas (,). By default, the port is **21007** for a security cluster and **9092** for a normal cluster.
- **client.sinks.kafka_sink.kafka.security.protocol**: The value is **SASL_PLAINTEXT** for a security cluster and **PLAINTEXT** for a normal cluster.
- **client.sinks.kafka_sink.kafka.kerberos.domain.name**:

  You do not need to set this parameter for a normal cluster. For a security cluster, the value of this parameter is the value of **kerberos.domain.name** in the Kafka cluster.

  Obtain the value by checking **${BIGDATA_HOME}/MRS_Current/1_*X*_Broker/etc/server.properties** on the node where the broker instance resides.

  In the preceding paths, **X** indicates a random number. Change it based on site requirements. The file must be saved by the user who installs the Flume client, for example, user **root**.

  Obtain the value by checking **${BIGDATA_HOME}/FusionInsight_Current/1_*X*_Broker/etc/server.properties** on the node where the broker instance resides.

Step 10 After the parameters are set and saved, the Flume client automatically loads the content configured in **properties.properties**. When new log files are generated by spoolDir, the files are sent to Kafka producers and can be consumed by Kafka consumers.

----End

6.3.4 Using an HBase Client

Scenario

This section describes how to use the HBase client in an O&M scenario or a service scenario.

Prerequisites

- The client has been installed. For example, the installation directory is **/opt/hadoopclient**. The client directory in the following operations is only an example. Change it to the actual installation directory.
- Service component users have been created by the MRS cluster administrator.

  A machine-machine user needs to download the **keytab** file and a human-machine user needs to change the password upon the first login.
- If a non-**root** user uses the HBase client, ensure that the owner of the HBase client directory is this user. Otherwise, run the following command to change the owner.

chown user:group -R *Client installation directory*/**HBase**

Using the HBase Client

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client directory:

cd /opt/hadoopclient

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If Kerberos authentication has been enabled for the current cluster, run the following command to authenticate the current user. The current user must have the permission to create HBase tables. If Kerberos authentication is disabled for the current cluster, skip this step.

kinit *Component service user*

For example, **kinit hbaseuser**.

Step 5 Run the following HBase client command:

hbase shell

----End

Common HBase client commands

The following table lists common HBase client commands.

Table 6-5 HBase client commands

Command	Description
create	Used to create a table, for example, **create 'test', 'f1', 'f2', 'f3'**.
disable	Used to disable a specified table, for example, **disable 'test'**.
enable	Used to enable a specified table, for example, **enable 'test'**.
alter	Used to alter the table structure. You can run the **alter** command to add, modify, or delete column family information and table-related parameter values, for example, **alter 'test', {NAME => 'f3', METHOD => 'delete'}**.
describe	Used to obtain the table description, for example, **describe 'test'**.
drop	Used to delete a specified table, for example, **drop 'test'**. Before deleting a table, you must stop it.
put	Used to write the value of a specified cell, for example, **put 'test','r1','f1:c1','myvalue1'**. The cell location is unique and determined by the table, row, and column.

Command	Description
get	Used to get the value of a row or the value of a specified cell in a row, for example, **get 'test','r1'**.
scan	Used to query table data, for example, **scan 'test'**. The table name and scanner must be specified in the command.

6.3.5 Using an HDFS Client

Scenario

This section describes how to use the HDFS client in an O&M scenario or service scenario.

Prerequisites

- The client has been installed.

  For example, the installation directory is **/opt/client**. The client directory in the following operations is only an example. Change it based on the actual installation directory onsite.
- Service component users have been created by the MRS cluster administrator. In security mode, machine-machine users need to download the keytab file. A human-machine user needs to change the password upon the first login. (This operation is not required in normal mode.)

Using the HDFS Client

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If the cluster is in security mode, run the following command to authenticate the user. In normal mode, user authentication is not required.

kinit *Component service user*

Step 5 Run the HDFS Shell command. Example:

hdfs dfs -ls /

----End

Common HDFS Client Commands

The following table lists common HDFS client commands.

Table 6-6 Common HDFS client commands

Command	Description	Example
hdfs dfs -mkdir *Folder name*	Used to create a folder.	**hdfs dfs -mkdir /tmp/mydir**
hdfs dfs -ls *Folder name*	Used to view a folder.	**hdfs dfs -ls /tmp**
hdfs dfs -put *Local file on the client node Specified HDFS path*	Used to upload a local file to a specified HDFS path.	**hdfs dfs -put /opt/test.txt /tmp** Upload the **/opt/test.txt** file on the client node to the **/tmp** directory of HDFS.
hdfs dfs -get *Specified file on HDFS Specified path on the client node*	Used to download the HDFS file to the specified local path.	**hdfs dfs -get /tmp/test.txt /opt/** Download the **/tmp/test.txt** file on HDFS to the **/opt** path on the client node.
hdfs dfs -rm -r -f *Specified folder on HDFS*	Used to delete a folder.	**hdfs dfs -rm -r -f /tmp/mydir**
hdfs dfs -chmod *Permission parameter File directory*	Used to configure the HDFS directory permission for a user.	**hdfs dfs -chmod 700 /tmp/test**

Client-related FAQs

1. What do I do when the HDFS client exits abnormally and error message "java.lang.OutOfMemoryError" is displayed after the HDFS client command is running?

   This problem occurs because the memory required for running the HDFS client exceeds the preset upper limit (128 MB by default). You can change the memory upper limit of the client by modifying **CLIENT_GC_OPTS** in *<Client installation path>***/HDFS/component_env**. For example, if you want to set the upper limit to 1 GB, run the following command:

   ```
   CLIENT_GC_OPTS="-Xmx1G"
   ```

   After the modification, run the following command to make the modification take effect:

   source <*Client installation path*>/**/bigdata_env**

2. How do I set the log level when the HDFS client is running?

   By default, the logs generated during the running of the HDFS client are printed to the console. The default log level is INFO. To enable the DEBUG log level for fault locating, run the following command to export an environment variable:

   export HADOOP_ROOT_LOGGER=DEBUG,console

   Then run the HDFS Shell command to generate the DEBUG logs.

If you want to print INFO logs again, run the following command:

export HADOOP_ROOT_LOGGER=INFO,console

3. How do I delete HDFS files permanently?

   HDFS provides a recycle bin mechanism. Typically, after an HDFS file is deleted, the file is moved to the recycle bin of HDFS. If the file is no longer needed and the storage space needs to be released, clear the corresponding recycle bin directory, for example, **hdfs://hacluster/user/xxx/.Trash/Current/***xxx*.

6.3.6 Using a Hive Client

Scenario

This section guides users to use a Hive client in an O&M or service scenario.

Prerequisites

- The client has been installed. For example, the client is installed in the **/opt/hadoopclient** directory. The client directory in the following operations is only an example. Change it to the actual installation directory.
- Service component users have been created by the MRS cluster administrator. In security mode, machine-machine users need to download the keytab file. A human-machine user must change the password upon the first login.

Using the Hive Client

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/hadoopclient

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Log in to the Hive client based on the cluster authentication mode.

- In security mode, run the following command to complete user authentication and log in to the Hive client:

  kinit *Component service user*

  beeline

- In common mode, run the following command to log in to the Hive client. If no component service user is specified, the current OS user is used to log in to the Hive client.

  beeline -n *component service user*

Step 5 Run the following command to execute the HCatalog client command:

hcat -e *"cmd"*

cmd must be a Hive DDL statement, for example, **hcat -e "show tables"**.

NOTE

- To use the HCatalog client, choose **More** > **Download Client** on the service page to download the clients of all services. This restriction does not apply to the beeline client.
- Due to permission model incompatibility, tables created using the HCatalog client cannot be accessed on the HiveServer client. However, the tables can be accessed on the WebHCat client.
- If you use the HCatalog client in Normal mode, the system performs DDL commands using the current user who has logged in to the operating system.
- Exit the beeline client by running the **!q** command instead of by pressing **Ctrl + C**. Otherwise, the temporary files generated by the connection cannot be deleted and a large number of junk files will be generated as a result.
- If multiple statements need to be entered during the use of beeline clients, separate the statements from each other using semicolons (**;**) and set the value of **entireLineAsCommand** to **false**.

  Setting method: If beeline has not been started, run the **beeline --entireLineAsCommand=false** command. If the beeline has been started, run the **!set entireLineAsCommand false** command.

  After the setting, if a statement contains semicolons (**;**) that do not indicate the end of the statement, escape characters must be added, for example, **select concat_ws('\;', collect_set(col1)) from tbl**.

----End

Common Hive Client Commands

The following table lists common Hive Beeline commands.

Table 6-7 Common Hive Beeline commands

Command	Description
set <key>=<value>	Sets the value of a specific configuration variable (key). **NOTE** If the variable name is incorrectly spelled, the Beeline does not display an error.
set	Prints the list of configuration variables overwritten by users or Hive.
set -v	Prints all configuration variables of Hadoop and Hive.
add FILE[S] <filepath> <filepath>* add JAR[S] <filepath> <filepath>* add ARCHIVE[S] <filepath> <filepath>*	Adds one or more files, JAR files, or ARCHIVE files to the resource list of the distributed cache.

Command	Description
add FILE[S] <ivyurl> <ivyurl>* add JAR[S] <ivyurl> <ivyurl>* add ARCHIVE[S] <ivyurl> <ivyurl>*	Adds one or more files, JAR files, or ARCHIVE files to the resource list of the distributed cache using the lvy URL in the **ivy://goup:module:version?query_string** format.
list FILE[S] list JAR[S] list ARCHIVE[S]	Lists the resources that have been added to the distributed cache.
list FILE[S] <filepath>* list JAR[S] <filepath>* list ARCHIVE[S] <filepath>*	Checks whether given resources have been added to the distributed cache.
delete FILE[S] <filepath>* delete JAR[S] <filepath>* delete ARCHIVE[S] <filepath>*	Deletes resources from the distributed cache.
delete FILE[S] <ivyurl> <ivyurl>* delete JAR[S] <ivyurl> <ivyurl>* delete ARCHIVE[S] <ivyurl> <ivyurl>*	Delete the resource added using **<ivyurl>** from the distributed cache.
reload	Enable HiveServer2 to discover the change of the JAR file **hive.reloadable.aux.jars.path** in the specified path. (You do not need to restart HiveServer2.) Change actions include adding, deleting, or updating JAR files.
dfs <dfs command>	Runs the **dfs** command.
<query string>	Executes the Hive query and prints the result to the standard output.

6.3.7 Using a Kafka Client

Scenario

You can create, query, and delete topics on a cluster client.

Prerequisites

The client has been installed in a directory, for example, **/opt/client**. The client directory in the following operations is only an example. Change it based on site requirements.

Using the Kafka Client

Step 1 Access the ZooKeeper instance page.

Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager**. Choose **Cluster** > *Name of the desired cluster* > **Services** > **ZooKeeper** > **Instance**.

Step 2 View the IP addresses of the ZooKeeper role instance.

Record any IP address of the ZooKeeper instance.

Step 3 Log in to the node where the client is installed.

Step 4 Run the following command to switch to the client installation directory, for example, **/opt/client/Kafka/kafka/bin**.

cd /opt/client/Kafka/kafka/bin

Step 5 Run the following command to configure environment variables:

source /opt/client/bigdata_env

Step 6 If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user. If Kerberos authentication is disabled for the current cluster, skip this step.

kinit *Kafka user*

Step 7 Log in to FusionInsight Manager, choose **Cluster** > **Name of the desired cluster** > **Services** > **ZooKeeper**, and click the **Configurations** tab and then **All Configurations**. On the displayed page, search for the **clientPort** parameter and record its value.

Step 8 Create a topic.

sh kafka-topics.sh --create --topic *Topic name* **--partitions** *Number of partitions occupied by the topic* **--replication-factor** *Number of replicas of the topic* **--zookeeper** *IP address of the node where the ZooKeeper instance resides:clientPort*/**kafka**

Example: **sh kafka-topics.sh --create --topic TopicTest --partitions 3 --replication-factor 3 --zookeeper 10.10.10.100:2181/kafka**

Step 9 Run the following command to view the topic information in the cluster:

sh kafka-topics.sh --list --zookeeper *IP address of the node where the ZooKeeper instance resides:clientPort*/**kafka**

Example: **sh kafka-topics.sh --list --zookeeper 10.10.10.100:2181/kafka**

Step 10 Delete the topic created in **Step 8**.

sh kafka-topics.sh --delete --topic *Topic name* **--zookeeper** *IP address of the node where the ZooKeeper instance resides*:*clientPort*/**kafka**

Example: **sh kafka-topics.sh --delete --topic TopicTest --zookeeper 10.10.10.100:2181/kafka**

----End

6.3.8 Using the Oozie Client

Scenario

This section describes how to use the Oozie client in an O&M scenario or service scenario.

Prerequisites

- The client has been installed in a directory, for example, **/opt/client**. The client directory in the following operations is only an example. Change it based on site requirements.
- Service component users have been created by the MRS cluster administrator. In security mode, machine-machine users need to download the keytab file. A human-machine user must change the password upon the first login.

Using the Oozie Client

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to switch to the client installation directory (change it to the actual installation directory):

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Check the cluster authentication mode.

- If the cluster is in security mode, run the following command to authenticate the user: *exampleUser* indicates the name of the user who submits tasks.

  kinit *exampleUser*

- If the cluster is in normal mode, go to **Step 5**.

Step 5 Perform the following operations to configure Hue:

1. Configure the Spark2x environment (skip this step if the Spark2x task is not involved):

   hdfs dfs -put /opt/client/Spark2x/spark/jars/*.jar /user/oozie/share/lib/spark2x/

   When the JAR package in the HDFS directory **/user/oozie/share** changes, you need to restart the Oozie service.

2. Upload the Oozie configuration file and JAR package to HDFS.

   hdfs dfs -mkdir /user/*exampleUser*

   hdfs dfs -put -f /opt/client/Oozie/oozie-client-*/examples /user/*exampleUser*/

NOTE

- *exampleUser* indicates the name of the user who submits tasks.
- If the user who submits the task and other files except **job.properties** are not changed, client installation directory **Oozie/oozie-client-*/examples** can be repeatedly used after being uploaded to HDFS.
- Resolve the JAR file conflict between Spark and Yarn about Jetty.

  hdfs dfs -rm -f /user/oozie/share/lib/spark/jetty-all-9.2.22.v20170606.jar
- In normal mode, if **Permission denied** is displayed during the upload, run the following commands:

  su - omm

  source /opt/client/bigdata_env

  hdfs dfs -chmod -R 777 /user/oozie

  exit

----End

6.3.9 Using a Storm Client

Scenario

This section describes how to use the Storm client in an O&M scenario or service scenario.

Prerequisites

- You have installed the client. For example, the installation directory is **/opt/hadoopclient**.
- Service component users have been created by the MRS cluster administrator. In security mode, machine-machine users have downloaded the keytab file. A human-machine user must change the password upon the first login. (Not involved in normal mode)

Procedure

Step 1 Prepare the client based on service requirements. Log in to the node where the client is installed.

Step 2 Run the following command to go to the client installation directory:

cd /opt/hadoopclient

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If multiple Storm instances are installed, run the following command to load the environment variables of a specific instance when running the Storm command to submit the topology. Otherwise, skip this step. The following command uses the instance Storm-2 as an example.

source Storm-2/component_env

Step 5 Run the following command to perform user authentication (skip this step in normal mode):

kinit *Component service user*

Step 6 Run the following command to perform operations on the client:

For example, run the following command:

- **cql**
- **storm**

NOTE

A Storm client cannot be connected to secure and non-secure ZooKeepers at the same time.

----End

6.3.10 Using a Yarn Client

Scenario

This section guides users to use a Yarn client in an O&M or service scenario.

Prerequisites

- The client has been installed.

  For example, the installation directory is **/opt/client**. The client directory in the following operations is only an example. Change it based on the actual installation directory onsite.
- Service component users have been created by the MRS cluster administrator. In security mode, machine-machine users need to download the keytab file. A human-machine user must change the password upon the first login. In common mode, you do not need to download the keytab file or change the password.

Using the Yarn Client

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If the cluster is in security mode, run the following command to authenticate the user. In normal mode, user authentication is not required.

kinit *Component service user*

Step 5 Run the Yarn command. The following provides an example:

yarn application -list

----End

Client-related FAQs

1. What Do I Do When the Yarn Client Exits Abnormally and Error Message "java.lang.OutOfMemoryError" Is Displayed After the Yarn Client Command Is Run?

   This problem occurs because the memory required for running the Yarn client exceeds the upper limit (128 MB by default) set on the Yarn client. You can modify **CLIENT_GC_OPTS** in *<Client installation path>***/HDFS/component_env** to change the memory upper limit of the Yarn client. For example, if you want to set the maximum memory to 1 GB, run the following command:

   ```
   export CLIENT_GC_OPTS="-Xmx1G"
   ```

   After the modification, run the following command to make the modification take effect:

   source *<Client installation path>*/**/bigdata_env**

2. How Can I Set the Log Level When the Yarn Client Is Running?

   By default, the logs generated during the running of the Yarn client are printed to the console. The default log level is INFO. To enable the DEBUG log level for fault locating, run the following command to export an environment variable:

   export YARN_ROOT_LOGGER=DEBUG,console

   Then run the Yarn Shell command to print DEBUG logs.

   If you want to print INFO logs again, run the following command:

   export YARN_ROOT_LOGGER=INFO,console

7 Configuring a Cluster with Decoupled Storage and Compute

7.1 MRS Storage-Compute Decoupling

In scenarios that require large storage capacity and elastic compute resources, MRS enables you to store data in OBS and use an MRS cluster for data computing only. In this way, storage and compute are separated.

NOTE

In the big data storage-compute decoupling scenario, the OBS parallel file system must be used to configure a cluster. Using common object buckets will greatly affect the cluster performance.

Perform the following steps to use the storage-compute decoupling function:

1. Configure a cluster with decoupled storage and compute.

   Select one of the following configurations (Using an agency is recommended.):

   - Bind an agency of the ECS type to an MRS cluster to access OBS, preventing the AK/SK from being exposed in the configuration file. For details, see **Configuring a Storage-Compute Decoupled Cluster (Agency)**.
   - Configure the AK/SK in an MRS cluster. The AK/SK will be exposed in the configuration file in plaintext. Exercise caution when performing this operation. For details, see **Configuring a Storage-Compute Decoupled Cluster (AK/SK)**.
   - MRS uses the Guardian component to connect to OBS, providing other components with the capabilities of obtaining temporary authentication credentials and fine-grained permission control for accessing OBS. For details, see **Interconnecting the Guardian Service with OBS**.

NOTE

- Currently, using Guardian components to connect to OBS is supported only in MRS 3.3.0-LTS or later versions. For details about configurations in clusters of other versions, see **Interconnecting MRS with OBS Using an Agency**.
- Job submission based on the Guardian storage and compute decoupling management plane depends on JobGateway instead of Executor.

2. Use the cluster.

   After the required permissions for accessing OBS are obtained, components in the MRS cluster can access the corresponding files through the client.

   For details about how to configure components to access OBS, see the following content:

   - **Interconnecting MRS with OBS Using an Agency**
   - **Interconnecting Components with OBS Using Guardian**

7.2 Interconnecting with OBS Using the Cluster Agency Mechanism

7.2.1 Configuring a Storage-Compute Decoupled Cluster (Agency)

MRS allows you to store data in OBS and use an MRS cluster for data computing only. In this way, storage and compute are separated. You can create an IAM agency, which enables ECS to automatically obtain the temporary AK/SK to access OBS. This prevents the AK/SK from being exposed in the configuration file.

By binding an agency, ECSs or BMSs can manage some of your resources. Determine whether to configure an agency based on the actual service scenario.

MRS provides the following configuration modes for accessing OBS. You can select one of them. The agency mode is recommended.

- Bind an agency of the ECS type to an MRS cluster to access OBS, preventing the AK/SK from being exposed in the configuration file. For details, see the following part in this section.
- Configure the AK/SK in an MRS cluster. The AK/SK will be exposed in the configuration file in plaintext. Exercise caution when performing this operation. For details, see **Configuring a Storage-Compute Decoupled Cluster (AK/SK)**.

  This function is available for components Hadoop, Hive, Spark, Presto, and Flink in clusters of .

(Optional) Step 1: Create an ECS Agency with OBS Access Permissions

NOTE

- MRS presets **MRS_ECS_DEFAULT_AGENCY** in the agency list of IAM so that you can select this agency when creating a cluster. This agency has the **OBSOperateAccess** permission and the **CESFullAccess** (only available for users who have enabled fine-grained policies), **CES Administrator**, and **KMS Administrator** permissions in the region where the cluster is located. Do not modify **MRS_ECS_DEFAULT_AGENCY** on IAM.
- If you want to use the preset agency, skip the step for creating an agency. If you want to use a custom agency, perform the following steps to create an agency. (To create or modify an agency, you must have the Security Administrator permission.) If you need fine-grained permission control on specified paths in the OBS file system, see **Configuring Fine-Grained Permissions for MRS Multi-User Access to OBS** and create custom role policies.

1. Log in to the management console.
2. Choose **Service List** > **Management & Governance** > **Identity and Access Management**.
3. Choose **Agencies**. On the displayed page, click **Create Agency**.
4. Enter an agency name, for example, **mrs_ecs_obs**.
5. Set **Agency Type** to **Cloud service** and select **ECS BMS** to authorize ECS or BMS to invoke OBS.
6. Set **Validity Period** to **Unlimited** and click **Next**.
7. On the displayed page, search for the **OBS OperateAccess** and select it.
8. Click **Next**. On the page that is displayed, select the desired scope for the permissions you selected. By default, **All resources** is selected. Click **Show More**, select **Global resources**, and click **OK**.
9. In the dialog box that is displayed, click **OK** to start authorization. After the message "**Authorization successful.**" is displayed, click **Finish**. The agency is successfully created.

Step 2: Create a Cluster with Storage and Compute Separated

You can configure an agency when creating a cluster or bind an agency to an existing cluster to separate storage and compute. This section uses a cluster with Kerberos authentication enabled as an example.

Configuring an agency when creating a cluster:

1. Click the **Custom Config** tab.
2. On the **Custom Config** tab page, set software parameters.
   - **Region**: Select a region as required.
   - **Cluster Name**: You can use the default name. However, you are advised to include a project name abbreviation or date for consolidated memory and easy distinguishing.
   - Cluster Version: Select a cluster version.
   - **Cluster Type**: Select **Analysis cluster** or **Hybrid cluster** and select all components.
   - **Metadata**: Select **Local**.
3. Click **Next** and set hardware parameters.

- **AZ**: Use the default value.
- **VPC**: Use the default value.
- **Subnet**: Use the default value.
- **Security Group**: Use the default value.
- **EIP**: Use the default value.
- **Cluster Node**: Select the number of cluster nodes and node specifications based on site requirements.

4. Click **Next** and set related parameters.
   - **Kerberos Authentication**: This function is enabled by default. You can enable or disable it.
   - **Username**: The default username is **admin**, which is used to log in to MRS Manager.
   - **Password**: Set a password for user **admin**.
   - **Confirm Password**: Enter the password of user **admin** again.
   - **Login Mode**: Select a method for logging in to ECSs. In this example, select **Password**.
   - **Username**: The default username is **root**, which is used to remotely log in to ECSs.
   - **Password**: Set a password for user **root**.
   - **Confirm Password**: Enter the password of user **root** again.
5. In this example, configure an agency and leave other parameters blank. For details about how to configure other parameters, see **Advanced Options**.

   Agency: Select the agency created in **(Optional) Step 1: Create an ECS Agency with OBS Access Permissions** or **MRS_ECS_DEFAULT_AGENCY** preset in IAM.
6. Select the check box for secure communications. For details, see **Communication Security Authorization**.
7. Click **Apply Now** and wait until the cluster is created.

   If Kerberos authentication is enabled for a cluster, check whether Kerberos authentication is required. If yes, click **Continue**. If no, click **Back** to disable Kerberos authentication and then create a cluster.

Configuring an agency for an existing cluster:

1. Log in to the MRS management console. In the left navigation pane, choose **Clusters** > **Active Clusters**.
2. Click the name of the cluster to enter its details page.
3. On the **Dashboard** page, click **Synchronize** on the right of **IAM User Sync** to synchronize IAM users.
4. On the **Dashboard** tab page, click **Manage Agency** on the right side of **Agency** to select an agency and click **OK** to bind it. Alternatively, click **Create Agency** to go to the IAM console to create an agency and select it.

Step 3: Create an OBS File System for Storing Data

NOTE

In storage-compute decoupled scenarios, the OBS parallel file system must be used to store data. The cluster performance will be significantly affected if common object buckets are used.

1. Log in to the OBS Console.
2. Choose **Parallel File System** > **Create Parallel File System**.
3. Enter the file system name, for example, **mrs-word001**.

   Set other parameters as required.
4. Click **Create Now**.
5. In the parallel file system list on the OBS console, click the file system name to go to the details page.
6. In the navigation pane, choose **Files** and create the **program** and **input** folders.
   - **program**: Upload the program package to this folder.
   - **input**: Upload the input data to this folder.

Step 4: Access the OBS File System

1. Log in to a Master node as user **root**. For details, see **Logging In to an ECS**.
2. Run the following command to set the environment variables:

   source /opt/Bigdata/client/bigdata_env
3. Verify that Hadoop can access OBS.
   a. View the list of files in the file system **mrs-word001**.

      hadoop fs -ls obs://mrs-word001/

   b. Check whether the file list is returned. If it is returned, OBS access is successful.

      Figure 7-1 Returned file list

      ```
      Found 2 items
      drwxrwxrwx   - root root          0 2019-12-21 11:04 obs://mrs-word001/input
      drwxrwxrwx   - root root          0 2019-12-21 11:04 obs://mrs-word001/program
      ```
4. Verify that Hive can access OBS.
   a. If Kerberos authentication has been enabled for the cluster, run the following command to authenticate the current user. The current user must have a permission to create Hive tables. If Kerberos authentication is disabled for the current cluster, skip this step.

      kinit *MRS cluster user*

      Example: **kinit hiveuser**

   b. Run the client command of the Hive component.

      beeline

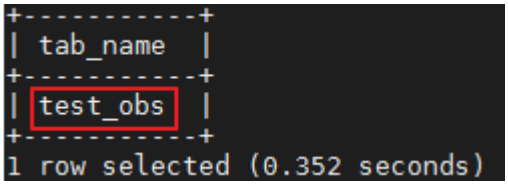
   c. Access the OBS directory in the beeline. For example, run the following command to create a Hive table and specify that data is stored in the **test_obs** directory of the file system **mrs-word001**:

create table test_obs(a int, b string) row format delimited fields terminated by ',' stored as textfile location "obs://mrs-word001/test_obs";

d. Run the following command to query all tables. If table **test_obs** is displayed in the command output, OBS access is successful.

show tables;

Figure 7-2 Returned table name



e. Press **Ctrl+C** to exit the Hive beeline.

5. Verify that Spark can access OBS.

a. Run the client command of the Spark component.

spark-beeline

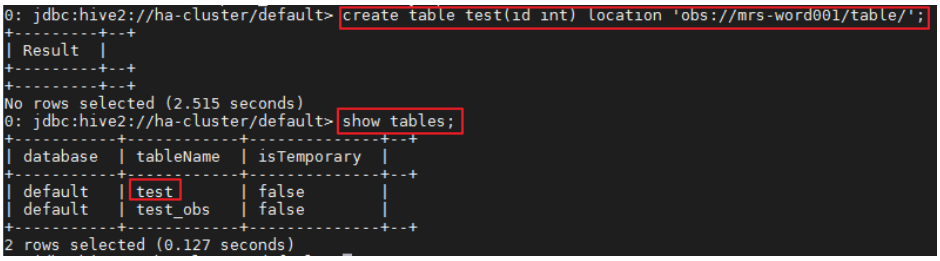
b. Access OBS in spark-beeline. For example, create table **test** in the **obs://mrs-word001/table/** directory.

create table test(id int) location 'obs://mrs-word001/table/';

c. Run the following command to query all tables. If table **test** is displayed in the command output, OBS access is successful.

show tables;

Figure 7-3 Returned table name



d. Press **Ctrl+C** to exit the Spark beeline.

6. Verify that Presto can access OBS.

– For normal clusters with Kerberos authentication disabled

i. Run the following command to connect to the client:

presto_cli.sh

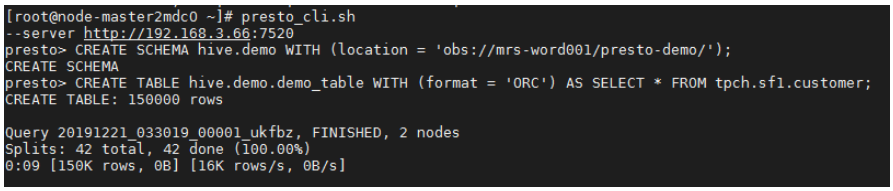
ii. On the Presto client, run the following statement to create a schema and set **location** to an OBS path:

CREATE SCHEMA hive.demo WITH (location = 'obs://mrs-word001/presto-demo002/');

iii. Create a table in the schema. The table data is stored in the OBS file system. The following is an example.

CREATE TABLE hive.demo.demo_table WITH (format = 'ORC') AS SELECT * FROM tpch.sf1.customer;

Figure 7-4 Return result



iv. Run **exit** to exit the client.

- For security clusters with Kerberos authentication enabled

  i. Log in to MRS Manager and create a role with the Hive Admin Privilege permissions, for example, **prestorole**. For details about how to create a role, see **Managing Roles**.

  ii. Create a user that belongs to the Presto and Hive groups and bind the role created in **6.i** to the user, for example, **presto001**. For details about how to create a user, see **Creating a User**.

  iii. Authenticate the current user.

  kinit presto001

  iv. Download the user credential.

  1) On FusionInsight Manager, choose **System > Permission > User**. In the row that contains the newly added user, click **More > Download Authentication Credential**.

  v. Decompress the downloaded user credential file, and save the obtained **krb5.conf** and **user.keytab** files to the client directory, for example, **/opt/Bigdata/client/Presto/**.

  vi. Run the following command to obtain a user principal:

  klist -kt /opt/Bigdata/client/Presto/user.keytab

  vii. For clusters with Kerberos authentication enabled, run the following command to connect to the Presto Server of the cluster:

  presto_cli.sh --krb5-config-path {krb5.conf file path} --krb5-principal {user principal} --krb5-keytab-path {user.keytab file path} --user {presto username}

  - **krb5.conf** file path: Replace it with the file path set in **6.v**, for example, **/opt/Bigdata/client/Presto/krb5.conf**.
  - **user.keytab** file path: Replace it with the file path set in **6.v**, for example, **/opt/Bigdata/client/Presto/user.keytab**.
  - **user principal**: Replace it with the result returned in **6.vi**.
  - **presto username**: Replace it with the name of the user created in **6.ii**, for example, **presto001**.

  Example: presto_cli.sh --krb5-config-path /opt/Bigdata/client/Presto/krb5.conf --krb5-principal prest001@xxx_xxx_xxx_xxx.COM --krb5-keytab-path /opt/Bigdata/client/Presto/user.keytab --user presto001

  viii. On the Presto client, run the following statement to create a schema and set **location** to an OBS path:

  CREATE SCHEMA hive.demo01 WITH (location = 'obs://mrs-word001/presto-demo002/');

  ix. Create a table in the schema. The table data is stored in the OBS file system. The following is an example.

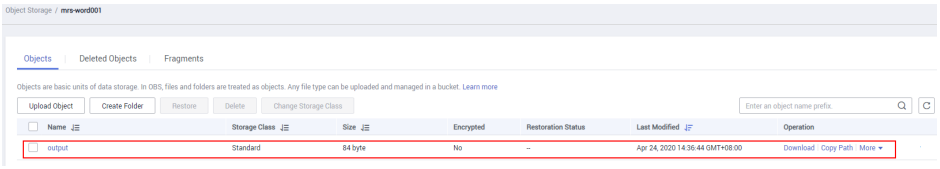
CREATE TABLE hive.demo01.demo_table WITH (format = 'ORC') AS SELECT * FROM tpch.sf1.customer;

Figure 7-5 Return result

x. Run **exit** to exit the client.

7. Verify that Flink can access OBS.
   a. On the **Dashboard** page, click **Synchronize** on the right of **IAM User Sync** to synchronize IAM users.
   b. After user synchronization is complete, choose **Jobs** > **Create** on the cluster details page to create a Flink job. In **Parameters**, enter parameters in **--input <Job input path> --output <Job output path>** format. You can click **OBS** to select a job input path, and enter a job output path that does not exist, for example, **obs://mrs-word001/output/**.
   c. On OBS Console, go to the output path specified during job creation. If the output directory is automatically created and contains the job execution results, OBS access is successful.

Figure 7-6 Flink job execution result



Step 5: Configure a Lifecycle Rule

In MRS 3.2.0-LTS.1 and later versions, components prevent mis-deletion by default. That is, file data deleted by component users is not directly deleted but stored in the recycle bin directory in the OBS file system.

To save OBS space, you need to enable periodical deletion of file data from the OBS recycle bin by referring to **Configuring the Policy for Clearing Component Data in the Recycle Bin**.

Reference

For details about how to control permissions to access OBS, see **Configuring Fine-Grained Permissions for MRS Multi-User Access to OBS**.

7.2.2 Configuring a Storage-Compute Decoupled Cluster (AK/SK)

In or later, OBS can be interconnected with MRS using **obs://**. Currently, Hadoop, Hive, Spark, Presto, and Flink are supported. HBase cannot use **obs://** to interconnect with OBS.

MRS provides the following configuration modes for accessing OBS. You can select one of them. The agency mode is recommended.

- Bind an agency of the ECS type to an MRS cluster to access OBS, preventing the AK/SK from being exposed in the configuration file. For details, see **Configuring a Storage-Compute Decoupled Cluster (Agency)**.
- Configure the AK/SK in an MRS cluster. The AK/SK will be exposed in the configuration file in plaintext. Exercise caution when performing this operation. For details, see the following part in this section.

NOTICE

- To improve data write performance, log in to the Manager and choose **Cluster** > **Services** > *Name of the service to be modified* > **Configurations**. Change the value of **fs.obs.buffer.dir** to the data disk directory.
- In the storage-compute decoupled scenario, the OBS parallel file system must be used to configure a cluster. For details, see . Using common object buckets will greatly affect the cluster performance.
- **In MRS 3.2.0-LTS.1 and later versions, components prevent mis-deletion by default. That is, file data deleted by component users is not directly deleted but stored in the recycle bin directory in the OBS file system.**

  To save OBS space, you need to enable periodical deletion of file data from the OBS recycle bin by referring to **Configuring the Policy for Clearing Component Data in the Recycle Bin**.
- Configuration files containing authentication passwords pose security risks. Delete such files after configuration or store them securely.
- Commands carrying authentication passwords pose security risks. Disable historical command recording before running such commands to prevent information leakage.

Using Hadoop to Access OBS

- Add the following content to the **core-site.xml** file in the *Client installation directory*/**HDFS/hadoop/etc/hadoop** directory on the HDFS client.

```
<property>
   <name>fs.obs.access.key</name>
   <value>ak</value>
</property>
<property>
   <name>fs.obs.secret.key</name>
   <value>sk</value>
</property>
<property>
   <name>fs.obs.endpoint</name>
   <value>obs endpoint</value>
</property>
```

  If you use commands that need to submit jobs to Yarn, such as **distcp**, you need to add the preceding content to the **core-site.xml** file in the Yarn directory (**$client_home/Yarn/config**) on the MRS client.

NOTICE

AK and SK will be displayed as plaintext in the configuration file. Exercise caution when setting AK and SK in the file.

After the configuration is added, you can directly access data on OBS without manually adding the AK/SK and endpoint. For example, run the following command to view the file list of the **test_obs_orc** directory in the **obs-test** file system:

hadoop fs -ls "obs://obs-test/test_obs_orc"

- Add AK/SK and endpoint to the command line to access data on OBS.

  hadoop fs -Dfs.obs.endpoint=xxx -Dfs.obs.access.key=xx -Dfs.obs.secret.key=xx -ls "obs://obs-test/ test_obs_orc"

Using Hive to Access OBS

Step 1 Log in to the service configuration page.

Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager**. Choose **Cluster > Services > Hive > Configurations**.

Step 2 In the configuration type drop-down box, switch **Basic Configurations** to **All Configurations**.

Step 3 Search for **fs.obs.access.key** and **fs.obs.secret.key** and set them to the AK and SK of OBS respectively.

If the preceding two parameters cannot be found in the current cluster, choose **Hive > Customization** in the navigation tree on the left and add the two parameters to the customized parameter **core.site.customized.configs**.

Step 4 Save the configurations and restart Hive.

Step 5 Access the OBS directory in Beeline. For example, run the following command to create a Hive table and specify that data is stored in the **test_obs** directory in the **test-bucket** file system:

create table test_obs(a int, b string) row format delimited fields terminated by "," stored as textfile location "obs://test-bucket/test_obs";

----End

Using Spark to Access OBS

NOTE

- SparkSQL depends on Hive. Therefore, when configuring OBS on Spark, you need to modify the OBS configuration used in **Using Hive to Access OBS**.
- In MRS 3.3.0-LTS and later versions, the Spark2x component is renamed Spark, and the role names in the component are also changed. For example, JobHistory2x is changed to JobHistory. Refer to the descriptions and operations related to the component name and role names in the document based on your MRS version.

- spark-beeline and spark-sql

You can use spark-beeline or spark-sql to log in to the Spark client and run the following commands to configure AK and SK information for accessing OBS:

set fs.obs.access.key=*AK*

set fs.obs.secret.key=*SK*

set fs.obs.endpoint=*OBS Endpoint*

- spark-beeline

  The spark-beeline can access OBS by configuring service parameters on Manager. The procedure is as follows:

  a. Log in to the service configuration page.

     Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager**. Choose **Cluster** > **Services** > **Spark2x** > **Configurations**.

  b. In the configuration type drop-down box, switch **Basic Configurations** to **All Configurations**.

  c. Choose **JDBCServer** > **OBS**, and set values for **fs.obs.access.key** and **fs.obs.secret.key**.

     If the preceding two parameters cannot be found in the current cluster, choose **JDBCServer** > **Customization** in the navigation tree on the left and add the two parameters to the customized parameter **spark.core-site.customized.configs**.

     Figure 7-7 Parameters for adding an OBS

     
  d. Save the configurations and restart Spark.

  e. Access OBS in **spark-beeline**. For example, access the **obs://obs-demo-input/table/** directory.

     create table test(id int) location 'obs://obs-demo-input/table/';

- spark-sql and spark-submit

  Both spark-sql and spark-submit can access OBS if you add the following content to the **core-site.xml** configuration file in the *Client installation directory*/**Spark/spark/conf** directory:

```
<property>
   <name>fs.obs.access.key</name>
   <value>ak</value>
</property>
<property>
   <name>fs.obs.secret.key</name>
   <value>sk</value>
</property>
<property>
   <name>fs.obs.endpoint</name>
   <value>obs endpoint</value>
</property>
```

Using Flink to Access OBS

Add the following configuration to the Flink configuration file of the MRS client in ***Client installation path*/Flink/flink/conf/flink-conf.yaml**:

```
fs.obs.access.key: ak
fs.obs.secret.key: sk
fs.obs.endpoint: OBS Endpoint
```

NOTICE

AK and SK will be displayed as plaintext in the configuration file. Exercise caution when setting AK and SK in the file.

After the configuration is added, you can directly access data on OBS without manually adding the AK/SK and endpoint.

7.2.3 Configuring the Policy for Clearing Component Data in the Recycle Bin

Scenario

By default, components in an MRS 3.2.0-LTS.1 or later cluster support prevention against accidental data deletion. Native HDFS garbage collection can be used in the Hadoop big data systems that use OBS.

The file data deleted by a component user is not directly deleted, but is stored in the recycle bin of the OBS file system instead. This section describes how to set a lifecycle rule for the recycle bin directory to periodically clear related data.

CAUTION

- **For clusters that use decoupled storage and compute, configure a lifecycle policy for the related directories by referring to this chapter. Otherwise, the storage space may be used up and storage fees may increase.**
- The recycle bin directory is created per user. When a user is created in the MRS cluster and the user has the permission to delete component data, you need to configure the recycle bin clearing rule for this new user.
- For HBase components that use decoupled storage and compute in MRS 3.1.2 or later versions, refer to this topic to set a policy for clearing component data in the recycle bin.

You need to configure lifecycle policies for the recycle bin directories of preset users in the MRS cluster and the recycle bin directories of new users who need accidental deletion prevention. If a low privileged agency is used or only the permission for MRS users to access OBS file system directories is configured by referring to **Configuring Fine-Grained Permissions for MRS Multi-User Access to OBS**, you will need the operation permission for the recycle bin directory.

Table 7-1 Directories for which a lifecycle policy needs to be configured

Cluster Version	Directory Type	Component	Directory	How to Create
Versions earlier than MRS 3.3.0-LTS	Recycle bin directories that must be configured by default for each component in an MRS cluster	Hive	• user/omm/.Trash • user/hive/.Trash	If the **.Trash** folder does not exist, create it on the cluster client as user **omm**. Run the following command: **hdfs dfs -mkdir -p obs://***Name of the OBS parallel file system where the table is stored***/***Folder path*
		Spark	• user/omm/.Trash • user/root/.Trash • user/spark2x/.Trash	
		HetuEngine	• user/omm/.Trash • user/hetuserver/.Trash	
		HBase	• user/hbase/.Trash • user/omm/.Trash • /hbase/archive	
	Recycle bin directories of users who need accidental deletion prevention	Hive/Spark/HetuEngine	user/*<New service user>*/.Trash	
MRS 3.3.0-LTS or later	Default recycle bin directories configured for each component in an MRS cluster	Hive/Spark/HetuEngine	/user/.Trash	

For example, if a new user in the cluster has the following permissions, you need to create a recycle bin directory clearing rule for the user in the parallel file system:

- Permissions to delete the HDFS files
- **DROP**, **INSERT OVERWRITE**, and **TRUNCATE** permissions on Hive tables

- **DROP**, **TRUNCATE**, **DELETE**, **INSERT OVERWRITE**, and **LOAD OVERWRITE** permissions on HetuEngine

Configuring the Lifecycle Rule of an OBS Directory

Step 1 Log in to the OBS console.

Step 2 Click **Parallel File Systems** and click the name of the file system used by the current MRS cluster.

Step 3 In the navigation pane on the left, choose **Basic Configurations** > **Lifecycle Rules**. Click **Create** to create a lifecycle rule for a specified directory..

Table 7-2 Parameters for creating a lifecycle rule

Name	Description	Example Value
Status	Whether to enable the lifecycle rule.	Enable
Rule Name	Rule name that identifies different lifecycle configurations.	rule-test
Prefix	Prefix of the objects to which the lifecycle rule applies. Objects that have the specified prefix will be managed by the lifecycle rule. The prefix cannot start with a slash (/), have consecutive slashes (/), or contain the following special characters: **\:*?"<>|** If this parameter is not specified, the rule will take effect for the entire file system. **NOTE** To prevent other service data from being deleted by mistake, you are not advised to use the lifecycle rule configured for the entire file system or high-level directories. Generally, the recycle bin directory of MRS components is in the following format. If the folder does not exist, create it. user/*<Username>*/.Trash	user/omm/.Trash
Delete Files After (Days)	The object within the rule configuration scope expires and is automatically deleted by OBS if the number of days since its last update reaches this parameter value.	30 days

Step 4 Click **OK** to complete the lifecycle rule configuration.

You can click **Edit** in the **Operation** column of a lifecycle rule to edit it. You can also click **Disable** or **Enable** to disable or enable it.

Step 5 Repeat the preceding steps to create recycle bin directory clearing rules for all users who have the data deletion permission in the current MRS cluster one by one until all recycle bin directories in the OBS file system are configured.

----End

7.2.4 Interconnecting MRS with OBS Using an Agency

7.2.4.1 Interconnecting Flink with OBS

Before performing the following operations, ensure that you have configured a storage-compute decoupled cluster by referring to **Configuring a Storage-Compute Decoupled Cluster (Agency)**.

Step 1 Log in to the Flink client installation node as the client installation user.

Step 2 Run the following command to initialize environment variables:

source *Client installation directory*/**bigdata_env**

Step 3 Configure the Flink client.

Step 4 Start a session.

- Normal cluster (Kerberos authentication disabled)

  yarn-session.sh -nm "*session-name***" -d**

- Security cluster (Kerberos authentication enabled)
  - If the **flink.keystore** and **flink.truststore** file paths are relative paths:

    Run the following command in the directory at the same level as **ssl** to start the session. **ssl/** is a relative path.

    cd /opt/hadoopclient/Flink/flink/conf/

    yarn-session.sh -t ssl/ -nm "*session-name***" -d**

    ```
    ...
    Cluster started: Yarn cluster with application id application_1624937999496_0017
    JobManager Web Interface: http://192.168.1.150:32261
    ```

  - If the **flink.keystore** and **flink.truststore** file paths are absolute paths:

    Run the following command to start a session:

    cd /opt/hadoopclient/Flink/flink/conf/

    yarn-session.sh -nm "*session-name***" -d**

Step 5 For a security cluster, run the following command to perform user authentication. If Kerberos authentication is not enabled for the current cluster, you do not need to run this command.

kinit *Username*

Step 6 Explicitly add the OBS file system to be accessed in the Flink command line.

echo -e 'test' >/tmp/test

hdfs dfs -mkdir -p obs://*Parallel file system name***/tmp/flinkjob**

hdfs dfs -put /tmp/test/ obs://*Parallel file system name***/tmp/flinkjob/**

flink run Client installation directory**/Flink/flink/examples/batch/WordCount.jar -input obs://***Parallel file system name***/tmp/flinkjob/test -output obs://***Parallel file system name***/tmp/flinkjob/output**

----End

NOTE

Flink jobs are running on Yarn. Before configuring Flink to interconnect with the OBS file system, ensure that the interconnection between Yarn and the OBS file system is normal.

7.2.4.2 Interconnecting Flume with OBS

This section applies to MRS 3.x or later.

Before performing the following operations, ensure that you have configured a storage-compute decoupled cluster by referring to **Configuring a Storage-Compute Decoupled Cluster (Agency)** or **Configuring a Storage-Compute Decoupled Cluster (AK/SK)**.

Step 1 Configure an agency.

1. Log in to the MRS console. In the navigation pane on the left, choose **Clusters** > **Active Clusters**.
2. Click the name of a cluster to go to the cluster details page.
3. On the **Dashboard** page, click **Synchronize** on the right of **IAM User Sync** to synchronize IAM users.
4. Click **Manage Agency** on the right of **Agency**, select the target agency, and click **OK**.

Step 2 Create an OBS file system for storing data.

1. Log in to the OBS console.
2. In the navigation pane on the left, choose **Parallel File Systems**. On the displayed page, click **Create Parallel File System**.
3. Enter the file system name, for example, **esdk-c-test-pfs1**, and set other parameters as required. Click **Create Now**.
4. In the parallel file system list on the OBS console, click the created file system name to go to its details page.
5. In the navigation pane on the left, choose **Files** and click **Create Folder** to create the **testFlumeOutput** folder.

Step 3 Prepare the **properties.properties** file and upload it to the **/opt/flumeInput** directory.

1. Prepare the **properties.properties** file on the local host. Its content is as follows:

```
# source
server.sources = r1
# channels
server.channels = c1
# sink
server.sinks = obs_sink
# ----- define net source -----
server.sources.r1.type = seq
server.sources.r1.spooldir = /opt/flumeInput
# ---- define OBS sink ----
server.sinks.obs_sink.type = hdfs
server.sinks.obs_sink.hdfs.path = obs://esdk-c-test-pfs1/testFlumeOutput
server.sinks.obs_sink.hdfs.filePrefix = %[localhost]
server.sinks.obs_sink.hdfs.useLocalTimeStamp = true
# set file size to trigger roll
server.sinks.obs_sink.hdfs.rollSize = 0
server.sinks.obs_sink.hdfs.rollCount = 0
```

```
server.sinks.obs_sink.hdfs.rollInterval = 5
#server.sinks.obs_sink.hdfs.threadsPoolSize = 30
server.sinks.obs_sink.hdfs.fileType = DataStream
server.sinks.obs_sink.hdfs.writeFormat = Text
server.sinks.obs_sink.hdfs.fileCloseByEndEvent = false

# define channel
server.channels.c1.type = memory
server.channels.c1.capacity = 1000
# transaction size
server.channels.c1.transactionCapacity = 1000
server.channels.c1.byteCapacity = 800000
server.channels.c1.byteCapacityBufferPercentage = 20
server.channels.c1.keep-alive = 60
server.sources.r1.channels = c1
server.sinks.obs_sink.channel = c1
```

NOTE

The value of **server.sinks.obs_sink.hdfs.path** is the OBS file system created in **Step 2**.

2. Log in to the node where the Flume client is installed as user **root**.
3. Create the **/opt/flumeInput** directory and create a customized **.txt** file in this directory.
4. Log in to FusionInsight Manager.
5. Choose **Cluster** > *Name of the target cluster* > **Services** > **Flume**. On the displayed page, click **Configurations** and then **Upload File** in the **Value** column corresponding to the **flume.config.file** parameter, upload the **properties.properties** file prepared in **Step 3.1**, and click **Save**.

Step 4 View the result in the OBS system.

1. Log in to the OBS console.
2. Click **Parallel File Systems** and go to the folder created in **Step 2** to view the result.

----End

7.2.4.3 Interconnecting HDFS with OBS

Before performing the following operations, ensure that you have configured a storage-compute decoupled cluster by referring to **Configuring a Storage-Compute Decoupled Cluster (Agency)** or **Configuring a Storage-Compute Decoupled Cluster (AK/SK)**.

Step 1 Log in to the node on which the HDFS client is installed as a client installation user.

Step 2 Run the following command to switch to the client installation directory.

cd *Client installation directory*

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If the cluster is in security mode, authenticate the user. In normal mode, skip user authentication.

kinit *Component service user*

Step 5 Explicitly add the OBS file system to be accessed in the HDFS command line.

For example:

- Run the following command to access the OBS file system:

  hdfs dfs -ls obs://*OBS parallel file system name***/***Path*

- Run the following command to upload the **/opt/test.txt** file from the client node to the OBS file system path:

  hdfs dfs -put /opt/test.txt obs://*OBS parallel file system name/Path*

----End

NOTE

If a large number of logs are printed in the OBS file system, the read and write performance may be affected. You can adjust the log level of the OBS client as follows:

cd *Client installation directory***/HDFS/hadoop/etc/hadoop**

vi log4j.properties

Add the OBS log level configuration to the file as follows:

log4j.logger.org.apache.hadoop.fs.obs=WARN

log4j.logger.com.obs=WARN

Figure 7-8 Adding an OBS log level

```
[root@node-master1AuKK hadoop]# tail -4 log4j.properties
log4j.logger.org.apache.commons.beanutils=WARN

log4j.logger.org.apache.hadoop.fs.obs=WARN
log4j.logger.com.obs=WARN
[root@node-master1AuKK hadoop]#
```

7.2.4.4 Interconnecting Hive with OBS

Before performing the following operations, ensure that you have configured a storage-compute decoupled cluster by referring to **Configuring a Storage-Compute Decoupled Cluster (Agency)** or **Configuring a Storage-Compute Decoupled Cluster (AK/SK)**.

Setting the Location to an OBS Path When Creating a Table

Step 1 Log in to the client installation node as the client installation user.

Step 2 Run the following command to initialize environment variables:

source *Client installation directory***/bigdata_env**

Step 3 For a security cluster, run the following command to perform user authentication (the user must have the permission to perform Hive operations). If Kerberos authentication is not enabled for the current cluster, you do not need to run this command.

kinit *User performing Hive operations*

Step 4 Click **Save** to save the configuration. On the **Dashboard** page, click **More** and select **Restart Service**. Enter the password of the current user, click **OK**, and select **Restart upper-layer services**. Click **OK** to restart Hive.

Step 5 Log in to the beeline client and set **Location** to the OBS file system path when creating a table.

beeline

For example, run the following command to create the table **test** in **obs://***OBS parallel file system name*/**user/hive/warehouse/***Database name*/*Table name*:

create table test(name string) location "obs://*OBS parallel file system name*/**user/hive/warehouse/***Database name*/*Table name*";

NOTE

You need to add the component operator to the URL policy in the Ranger policy. Set the URL to the complete path of the object on OBS. Select the Read and Write permissions.

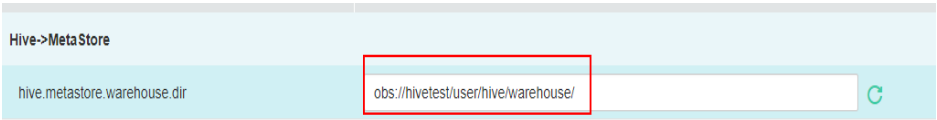
----End

Interconnecting Hive with OBS Through MetaStore

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Hive** > **Configurations** > **All Configurations**.

Search for **hive.metastore.warehouse.dir** in the search box and change the parameter value to an OBS path, for example, **obs://hivetest/user/hive/warehouse/**. **hivetest** indicates the OBS file system name.

Figure 7-9 Configuring **hive.metastore.warehouse.dir**



Step 2 Save the change and restart Hive.

Step 3 (Optional) Install the client by referring to **Installing a Client**. If the client has been installed in the cluster, go to **Step 4**.

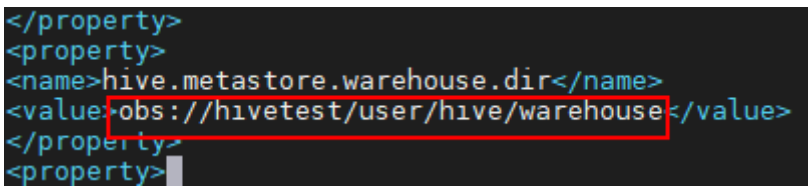
Step 4 Update the client configuration file.

1. Run the following command to open **hivemetastore-site.xml** in the Hive configuration file directory on the client:

   vim *Client installation directory*/**Hive/config/hivemetastore-site.xml**

2. Change the value of **hive.metastore.warehouse.dir** to the corresponding OBS path, for example, **obs://hivetest/user/hive/warehouse/**, where **hivetest** is the OBS bucket name.

Figure 7-10 Configuring the OBS Path



3. Change the value of **hive.metastore.warehouse.dir** in **hivemetastore-site.xml** to the corresponding OBS path, for example, **obs://hivetest/user/hive/warehouse/**. The XML file is stored in the HCatalog client configuration file directory.

   vi *Client installation directory*/**Hive/HCatalog/conf/hivemetastore-site.xml**

Step 5 Log in to the beeline client, create a table, and check whether the location is the OBS path.

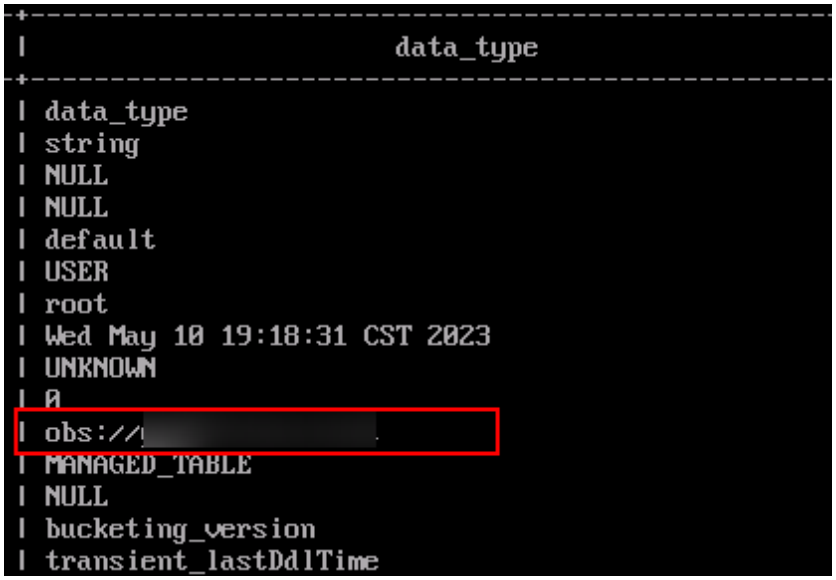
beeline

create table test(name string);

desc formatted test;

Location of the table is the OBS path.

Figure 7-11 Location of the Hive table



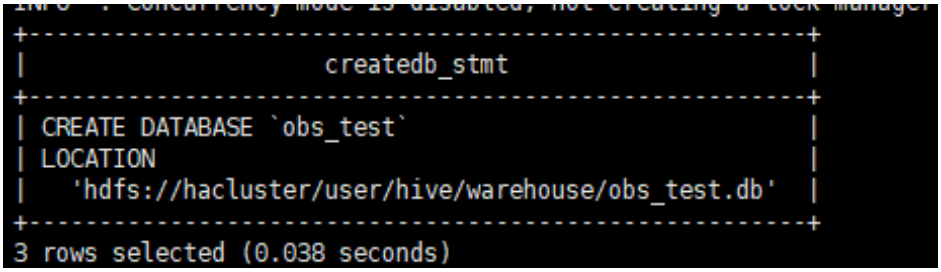
NOTE

If the location of the current database points to HDFS, tables created in the database also point to HDFS by default. You do not need to specify the location. To modify the default table creation policy, modify the location of the database to point to OBS. Perform the following steps to modify the parameters:

1. Run the following command to query the location of the database:

   show create database *obs_test*;

   Figure 7-12 Viewing the location of the Hive Table

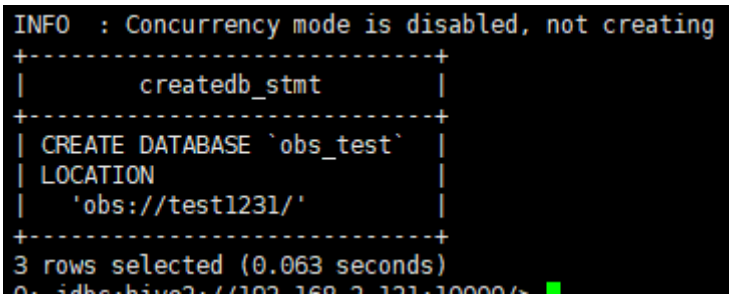
   


2. Run the following command to change the database location:

   alter database *obs_test* **set location** '**obs://***OBS parallel file system name*/**user/hive/warehouse/***Database name*'

   Run the **show create database** *obs_test* command to check whether the database location points to OBS.

   Figure 7-13 Check the location of the modified Hive table.

3. Run the following command to modify the table location:

   alter table *user_info* **set location** '**obs://***OBS parallel file system name*/**user/hive/warehouse/***Database name*/*Table name*'

   If the table contains data, migrate the original data file to the new location.

----End

7.2.4.5 Interconnecting MapReduce with OBS

Before performing the following operations, ensure that you have configured a storage-compute decoupled cluster by referring to **Configuring a Storage-Compute Decoupled Cluster (Agency)** or **Configuring a Storage-Compute Decoupled Cluster (AK/SK)**.

Step 1 Log in to the MRS management console and click the cluster name to go to the cluster details page.

Step 2 Choose **Components > MapReduce**. The **All Configurations** page is displayed. In the navigation tree on the left, choose **MapReduce > Customization**. In the

customized configuration items, add the configuration item **mapreduce.jobhistory.always-scan-user-dir** to **core-site.xml** and set its value to **true**.

Figure 7-14 Adding a custom parameter

Step 3 Save the configurations and restart the MapReduce service.

----End

7.2.4.6 Interconnecting Spark2x with OBS

The OBS file system can be interconnected with Spark2x after an MRS cluster is installed.

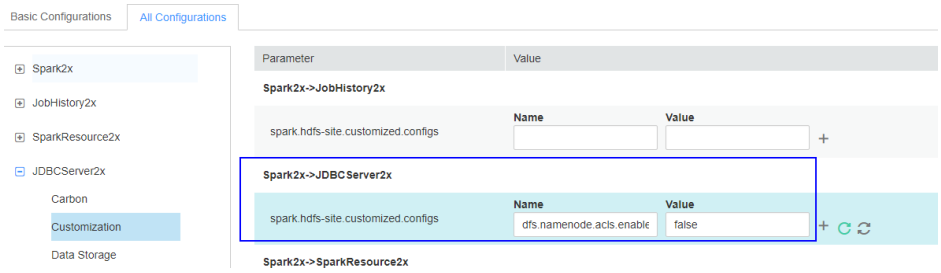
Before performing the following operations, ensure that you have configured a storage-compute decoupled cluster by referring to **Configuring a Storage-Compute Decoupled Cluster (Agency)** or **Configuring a Storage-Compute Decoupled Cluster (AK/SK)**.

Verifying OBS Access with Spark Beeline

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Spark2x** > **Configurations** > **All Configurations**.

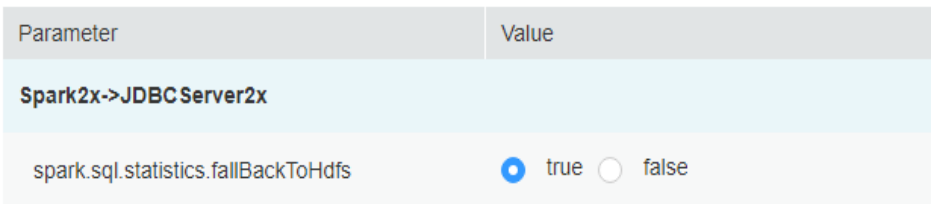
In the left navigation tree, choose **JDBCServer2x** > **Customization**. Add **dfs.namenode.acls.enabled** to the **spark.hdfs-site.customized.configs** parameter and set its value to **false**.

Figure 7-15 Adding Spark custom parameters



Step 2 Search for the **spark.sql.statistics.fallBackToHdfs** parameter and set its value to **false**.

Figure 7-16 Setting **spark.sql.statistics.fallBackToHdfs**



Step 3 Save the configurations and restart the JDBCServer2x instance.

Step 4 Log in to the client installation node as the client installation user.

Step 5 Run the following commands to configure environment variables:

source *Client installation directory*/**bigdata_env**

Step 6 For a security cluster, run the following command to perform user authentication. If Kerberos authentication is not enabled for the current cluster, you do not need to run this command.

kinit *Username*

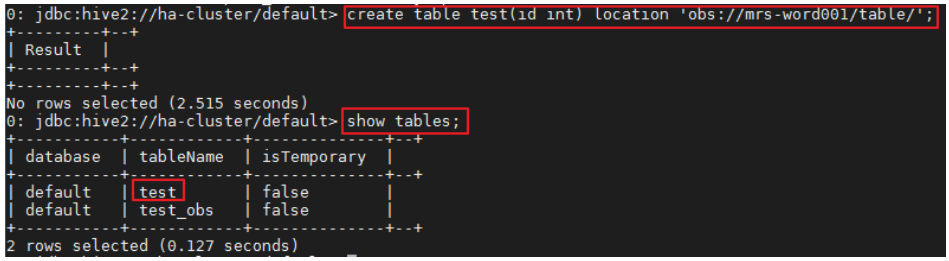
Step 7 Access OBS using Spark beeline. The following example creates a table named **test** in the **obs://mrs-word001/table/** directory.

create table test(id int) location '*obs://mrs-word001/table/*';

Step 8 Run the following command to query all tables. If table **test** is returned, OBS access is successful.

show tables;

Figure 7-17 Returned table names



Step 9 Press **Ctrl+C** to exit Spark beeline.

----End

Verifying OBS Access with Spark SQL

Step 1 Log in to the client installation node as the client installation user.

Step 2 Run the following commands to configure environment variables:

source *Client installation directory*/**bigdata_env**

Step 3 Modify the configuration file:

vim *Client installation directory*/**Spark2x/spark/conf/hdfs-site.xml**

```
<property>
<name>dfs.namenode.acls.enabled</name>
<value>false</value>
</property>
```

Step 4 For a security cluster, run the following command to perform user authentication. If Kerberos authentication is not enabled for the current cluster, you do not need to run this command.

kinit *Username*

Step 5 Access OBS using Spark SQL CLI. For example, create a table named **test** in the **obs://mrs-word001/table/** directory.

1. Go to the **cd** *Client installation directory*/**Spark2x/spark/bin** directory and run the **./spark-sql** command to log in to the Spark SQL CLI.
2. Run the following command in the Spark SQL CLI:

   create table test(id int) location '*obs://mrs-word001/table/*';

Step 6 Run the **show tables;** command to confirm that the table is created successfully.

Step 7 Run **exit;** to exit the Spark SQL CLI.

NOTE

If a large number of logs are printed in the OBS file system, read and write performance may be affected. You can adjust the log level of the OBS client as follows:

cd *Client installation directory*/**Spark2x/spark/conf**

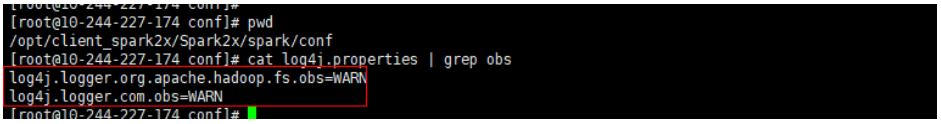
vi log4j.properties

Add the OBS log level configuration to the file as follows:

log4j.logger.org.apache.hadoop.fs.obs=WARN

log4j.logger.com.obs=WARN

Figure 7-18 Adding an OBS log level



----End

Using Spark Shell to Read OBS Files

Step 1 Log in to the client installation node as the client installation user.

Step 2 Run the following commands to configure environment variables:

source *Client installation directory*/**bigdata_env**

Step 3 Modify the configuration file:

vim *Client installation directory*/**Spark2x/spark/conf/hdfs-site.xml**

```
<property>
<name>dfs.namenode.acls.enabled</name>
<value>false</value>
</property>
```

Step 4 For a security cluster, run the following command to perform user authentication. If Kerberos authentication is not enabled for the current cluster, you do not need to run this command.

kinit *Username*

Step 5 Create an OBS file.

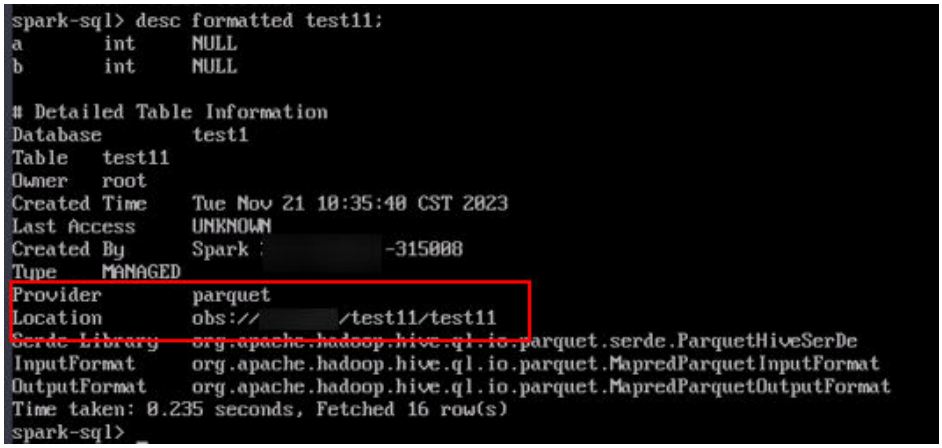
1. Run the following commands to log in to the Spark SQL CLI:

   cd *Client installation directory*/**Spark2x/spark/conf**

   ./spark-sql

2. Run the following commands to create a table and import data to the table:
   create database *test* **location "obs://***Parallel file system path/test***";**
   use *test*;
   create table *test1*(a int,b int) **using parquet;**
   insert into *test1* **values(1,2);**
   desc formatted *test1*;

   Figure 7-19 Checking the location of the table



Step 6 Run the following command to go to the Spark **bin** directory:

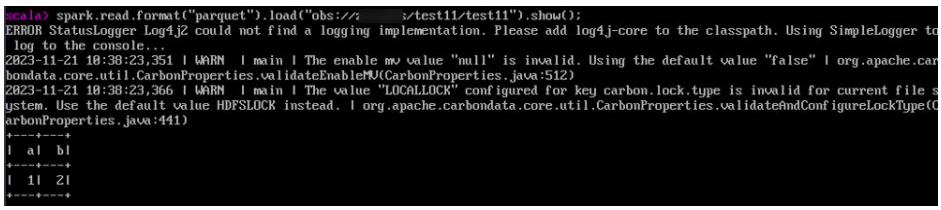
cd *Client installation directory*/**Spark2x/spark/conf**

Run **./spark-sql** to log in to the Spark SQL CLI.

Step 7 In the Spark Shell CLI, run the following command to query the table created in **Step 5.2**:

spark.read.format("parquet").load ("obs://*Parallel file system path/test1***").show();**

Figure 7-20 Viewing table data



Step 8 Run the **:quit** command to exit the Spark Shell CLI.

----End

7.2.4.7 Interconnecting Sqoop with External Storage Systems

Before you start operations in this section, you have interconnected the HDFS client with OBS by referring to **Configuring a Storage-Compute Decoupled Cluster (Agency)**. You also need to download the MySQL driver package of the required version from the MySQL official website **https://downloads.mysql.com/**

archives/c-j/, decompress the package, and upload it to *Client installation directory*/**Sqoop/sqoop/lib** directory on the node where the Sqoop client is installed.

Exporting Data from HDFS to MySQL

Step 1 Log in to the node where the client is located.

Step 2 Run the following command to initialize environment variables:

source /opt/client/bigdata_env

Step 3 Run the following command to operate the Sqoop client:

sqoop export --connect jdbc:mysql://10.100.*xxx.xxx***:***3306/test* **--username root --password** *xxx* **--table** *component13* **-export-dir hdfs://hacluster/***user/hive/warehouse/component_test3* **--fields-terminated-by ',' -m 1**

Table 7-3 Parameter description

Parameter	Description
--connect	Specifies the URL for connecting to JDBC. The value is in **jdbc:mysql://***IP address of the MySQL database*:*MySQL Port*/*Database name* format.
--username	Specifies the username for connecting to the MySQL database.
-password	Specifies the password for connecting to the MySQL database. There can be security risks if a command contains the authentication password. You are advised to disable the command recording function (history) before running the command.
-table <table-name>	Specifies the name of the MySQL table used to store exported data.
-export-dir <dir>	Specifies the HDFS path of the Sqoop table to be exported.
--fields-terminated-by	Specifies the delimiter of the exported data, which must be the same as that in the HDFS data table to be exported.
-m or -num-mappers <n>	Starts *n* (4 by default) maps to import data concurrently. The value cannot be greater than the maximum number of maps in a cluster.
-direct	Imports data to a relational database using a database import tool, for example, mysqlimport of MySQL, more efficient than the JDBC connection mode.
-update-key <col-name>	Specifies the column used for updating the existing data in a relational database.

Parameter	Description
-update-mode <mode>	Specifies how updates are performed. The value can be **updateonly** or **allowinsert**. This parameter is used only when the relational data table does not contain the data record to be imported. For example, if the HDFS data to be imported to the destination table contains a data record **id=1** and the table contains an existing data record **id=2**, the update will fail.
-input-null-string <null-string>	This parameter is optional. If it is not specified, **null** will be used.
-input-null-non-string <null-string>	This parameter is optional. If it is not specified, **null** will be used.
-staging-table <staging-table-name>	Creates a table with the same data structure as the destination table for storing data before it is imported to the destination table. This parameter ensures the transaction security when data is imported to a relational database table. Due to multiple transactions during an import, this parameter can prevent other transactions from being affected when one transaction fails. For example, the imported data is incorrect or duplicate records exist.
-clear-staging-table	Clears data in the staging table before data is imported if the staging-table is not empty.

----End

Importing Data from MySQL to Hive

Step 1 Log in to the node where the client is located.

Step 2 Run the following command to initialize environment variables:

source /opt/client/bigdata_env

Step 3 Run the following command to operate the Sqoop client:

sqoop import --connect jdbc:mysql://10.100.*xxx.xxx***:3306/***test* **--username root --password** *xxx* **--table component --hive-import --hive-table** *component_test2* **--delete-target-dir --fields-terminated-by "," -m 1 --as-textfile**

Table 7-4 Parameter description

Parameter	Description
--hive-import	Imports data from a relational database to MRS Hive.
--delete-target-dir	Deletes the existing target file (if any) from Hive and imports again.

Parameter	Description
-append	Appends data to an existing dataset in the HDFS. Once this parameter is used, Sqoop imports data to a temporary directory, renames the temporary file where the data is stored, and moves the file to a formal directory to avoid duplicate file names in the directory.
-as-avrodatafile	Imports data to a data file in the Avro format.
-as-sequencefile	Imports data to a sequence file.
-as-textfile	Import data to a text file. After the text file is generated, you can run SQL statements in Hive to query the result.
-boundary-query <statement>	Specifies the SQL statement for performing boundary query. Before importing data, use a SQL statement to obtain a result set and import the data in the result set. The data format can be **-boundary-query 'select id,creationdate from person where id = 3'** (indicating a data record whose ID is 3) or **select min(<split-by>), max(<split-by>) from <table name>**. The fields to be queried cannot contain fields whose data type is string. Otherwise, the error message "java.sql.SQLException: Invalid value for getLong()" is displayed.
-columns<col,col,col...>	Specifies the fields to be imported. The format is ***-Column id,Username***.
-direct	Imports data to a relational database using a database import tool, for example, mysqlimport of MySQL, more efficient than the JDBC connection mode.
-direct-split-size	Splits the imported streams by byte. Especially when data is imported from PostgreSQL using the direct mode, a file that reaches the specified size can be divided into several independent files.
-inline-lob-limit	Sets the maximum value of an inline LOB.
-m or -num-mappers	Starts *n* (4 by default) maps to import data concurrently. The value cannot be greater than the maximum number of maps in a cluster.
-query, -e<statement>	Imports data from the query result. To use this parameter, you must specify the **-target-dir** and **-hive-table** parameters and use the query statement containing the WHERE clause as well as $CONDITIONS. Example: **-query'select * from person where $CONDITIONS' -target-dir /user/hive/warehouse/person -hive-table person**

Parameter	Description
-split-by<column-name>	Specifies the column of a table used to split work units. Generally, the column name is followed by the primary key ID.
-table <table-name>	Specifies the relational database table from which data is obtained.
-target-dir <dir>	Specifies the HDFS path.
-warehouse-dir <dir>	Specifies the directory for storing data to be imported. This parameter is applicable when data is imported to HDFS but cannot be used when you import data to Hive directories. This parameter cannot be used together with **-target-dir**.
-where	Specifies the WHERE clause when data is imported from a relational database, for example, **-where 'id = 2'**.
-z,-compress	Compresses sequence, text, and Avro data files using the GZIP compression algorithm. Data is not compressed by default.
–compression-codec	Specifies the Hadoop compression codec. GZIP is used by default.
–null-string <null-string>	Specifies the string to be interpreted as **NULL** for string columns.
–null-non-string<null-string>	Specifies the string to be interpreted as null for non-string columns. If this parameter is not specified, **NULL** will be used.
-check-column (col)	Specifies the column for checking incremental data import, for example, **id**.
-incremental (mode) append or last modified	Incrementally imports data. **append**: appends records, for example, appending records that are greater than the value specified by **last-value**. **lastmodified**: appends data that is modified after the date specified by **last-value**.
-last-value (value)	Specifies the maximum value (greater than the specified value) of the column after the last import. This parameter can be set as required.

----End

Sqoop Usage Example

- Importing data from MySQL to HDFS using the **sqoop import** command

sqoop import --connect jdbc:mysql://10.100.231.134:3306/test --username root --password *xxx* --query 'SELECT * FROM component where $CONDITIONS and component_id ="MRS 1.0_002"' --target-dir /tmp/component_test --delete-target-dir --fields-terminated-by "," -m 1 --as-textfile

- Exporting data from OBS to MySQL using the **sqoop export** command

  sqoop export --connect jdbc:mysql://10.100.231.134:3306/test --username root --password *xxx* --table component14 -export-dir obs://obs-file-bucket/xx/part-m-00000 --fields-terminated-by ',' -m 1

- Importing data from MySQL to OBS using the **sqoop import** command

  sqoop import --connect jdbc:mysql://10.100.231.134:3306/test --username root --password *xxx* --table component --target-dir obs://obs-file-bucket/xx --delete-target-dir --fields-terminated-by "," -m 1 --as-textfile

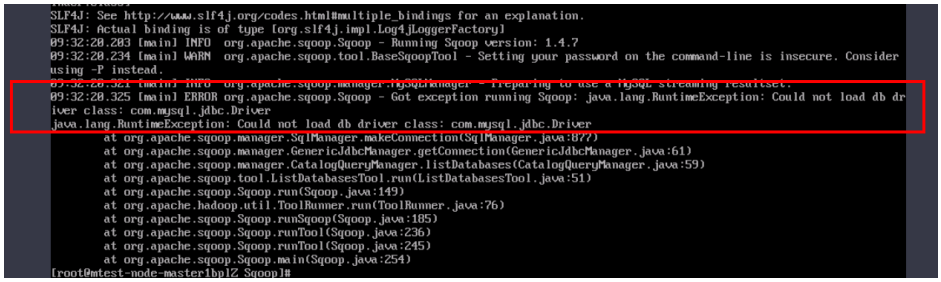
- Importing data from MySQL to OBS tables outside Hive

  sqoop import --connect jdbc:mysql://10.100.231.134:3306/test --username root --password *xxx* --table component --hive-import --hive-table component_test01 --fields-terminated-by "," -m 1 --as-textfile

MySQL Driver Package Is Missing During Data Import or Export

If the error "Could not load db driver class: com.mysql.jdbc.Driver" is reported when you run the **sqoop import** or **sqoop export** command, the MySQL driver package is missing. Download the MySQL driver package from the MySQL official website, decompress it, upload it to the *Client installation directory*/**Sqoop/sqoop/lib**, and run the command again.

Figure 7-21 An error indicating that the MySQL driver package is missing



7.2.4.8 Interconnecting Hudi with OBS

Step 1 Log in to the client installation node as the client installation user.

Step 2 Run the following commands to configure environment variables:

source *Client installation directory*/**bigdata_env**

source *Client installation directory*/**Hudi/component_env**

Step 3 Modify the configuration file:

vim *Client installation directory*/**Hudi/hudi/conf/hdfs-site.xml**

```
<property>
<name>dfs.namenode.acls.enabled</name>
<value>false</value>
</property>
```

Step 4 For a security cluster, run the following command to perform user authentication. If Kerberos authentication is not enabled for the current cluster, you do not need to run this command.

kinit *Username*

Step 5 Start spark-shell and run the following commands to create a COW table and save it in OBS:

```
import org.apache.hudi.QuickstartUtils._
import scala.collection.JavaConversions._
import org.apache.spark.sql.SaveMode._
import org.apache.hudi.DataSourceReadOptions._
import org.apache.hudi.DataSourceWriteOptions._
import org.apache.hudi.config.HoodieWriteConfig._
val tableName = "hudi_cow_table"
val basePath = "obs://testhudi/cow_table/"
val dataGen = new DataGenerator
val inserts = convertToStringList(dataGen.generateInserts(10))
val df = spark.read.json(spark.sparkContext.parallelize(inserts, 2))
df.write.format("org.apache.hudi").
options(getQuickstartWriteConfigs).
option(PRECOMBINE_FIELD_OPT_KEY, "ts").
option(RECORDKEY_FIELD_OPT_KEY, "uuid").
option(PARTITIONPATH_FIELD_OPT_KEY, "partitionpath").
option(TABLE_NAME, tableName).
mode(Overwrite).
save(basePath);
```

NOTE

obs://testhudi/cow_table/ is the OBS path, and **testhudi** is the bucket name. Change them based on site requirements.

Step 6 Use DataSource to check whether the table is successfully created and whether the data is normal.

```
val roViewDF = spark.
read.
format("org.apache.hudi").
load(basePath + "/*/*/*/*")
roViewDF.createOrReplaceTempView("hudi_ro_table")
```

spark.sql("select * from hudi_ro_table").show()

Step 7 Run the **:q** command to exit the spark-shell CLI.

----End

7.2.5 Configuring Fine-Grained Permissions for MRS Multi-User Access to OBS

When fine-grained permission control is enabled, you can configure OBS access permissions to implement access control on directories in OBS file systems.

This function enables you to control MRS users' access to OBS resources. For example, if you allow user group A to only access log files in a specified OBS file system, perform the following operations:

1. Configure an agency with OBS access permissions for an MRS cluster so that OBS can be accessed using the temporary AK/SK automatically obtained by the ECS. This prevents the AK/SK from being exposed in the configuration file.
2. Create a policy on the IAM console to allow access to log files in a specified OBS file system, and create an agency bound to the policy permission.
3. In the MRS cluster, bind the new agency to user group A so that user group A only has the permission to access log files in the specified OBS file system.

In the following scenarios, the username used for submitting jobs is an internal username so that MRS multi-user access to OBS is not supported.

- For spark-beeline, the internal username used for submitting jobs is **spark** in a security cluster and **omm** in a normal cluster.
- For the HBase shell, the internal username used for submitting jobs is **hbase** in a security cluster and **omm** in a normal cluster.
- For Presto, the internal username used for submitting jobs in the security cluster is **omm** or **hive**, and that in the normal cluster is **omm**. (Choose **Components** > **Presto** > **Service Configuration**. Change **Basic** to **All** in the parameter type drop-down box.) Then, search for and change the value of **hive.hdfs.impersonation.enabled** to **true** to enable MRS multi-user to access OBS with fine-grained permissions.

Prerequisites

- Fine-grained permission control has been enabled. For details about permissions management, see **Creating an MRS User**.
- You have a basic knowledge of **IAM Agencies** (see section "Agencies" in the *IAM User Guide*) and OBS fine-grained policies.

Step 1: Configuring an Agency with OBS Access Permission for a Cluster

Follow instructions in **Configuring a Storage-Compute Decoupled Cluster (Agency)** to configure an agency with OBS access permissions.

The agency takes effect for all users (including internal users) and user groups in the cluster. To control the permissions of users and user groups in the cluster to access OBS, perform the following operations.

NOTE

When you configure permissions on an OBS path, if the write permission is configured, you need to configure the corresponding recycle bin path.

The default recycle bin path is **/user/${current.user}/.Trash/**, in which **${current.user}** indicates the current user.

Step 2: Creating a Policy and an Agency on IAM

Create policies with different access permissions and bind the policies to the agency. For details, see **Creating a Policy and an Agency on IAM**.

Step 3: Configuring OBS Permission Control Mappings on the MRS Cluster Details Page

Step 1 On the MRS management console, choose **Clusters** > **Active Clusters** and click the cluster name.

Step 2 In the **Basic Information** area on the **Dashboard** tab page, click **Manage** next to **OBS Permission Control**.

Step 3 Click **Add Mapping** and set parameters according to **Table 7-5**.

Table 7-5 OBS permission control parameters

Parameter	Description
IAM Agency	Select the agency created in **Step 2**.
Type	• **User**: User-level mapping • **Group**: User group-level mapping **NOTE** • User-level mapping takes priority over user group-level mapping. If you select **Group**, you are advised to enter the primary group name in **MRS User (User Group)**. • Do not use the same username (user group) for multiple mapping records.

Parameter	Description
MRS User (User Group)	Use commas (,) to separate multiple names of users or user groups. **NOTE** • If OBS permission control is not configured for a user and no AK and SK are configured, the OBS Operator permission in **MRS_ECS_DEFAULT_AGENCY** will be used for accessing OBS. You are advised not to bind the internal user of a component to an agency. • If you need to configure an agency for the internal user of a component when submitting a job in the following scenarios, the requirements are as follows: – To control permissions on spark-beeline operations, set the username to **spark** for a security cluster and **omm** for a normal cluster. – To control permissions on HBase shell operations, set the username to **hbase** for a security cluster and **omm** for a normal cluster. – To control permissions on Presto, set the username to **omm**, **hive**, and the username used for logging in to the client for a security cluster and **omm** and the username used for logging in to the client for a normal cluster. – If you want to use Hive to create tables in beeline mode, set the username to the internal user **hive**.

Step 4 Click **OK**.

Step 5 Select **I agree to authorize the trust relationships between MRS Users (Groups) and IAM agencies**, and click **OK**. The mapping between the MRS user and OBS permission is added.

If appears next to **OBS Permission Control** on the **Dashboard** tab page or the mapping table has been updated for OBS permission control, the mapping takes effect. It takes about 1 minute to for the mapping to take effect.

In the **Operation** column of the mapping list, you can edit or delete the added mapping.

NOTE

- If OBS permission control is not configured for a user and no AK and SK are configured, the permissions owned by the agency configured for the cluster in the **Object Storage Service (OBS)** project will be used to access OBS.
- Regardless of whether OBS permission control is configured, AK/SK permission is used for accessing OBS once it is configured.
- Security Administrator permission is required to modify, create, or delete a mapping.
- To apply the mapping changes in spark-beeline, hive beeline, and Presto, you need to restart Spark, exit beeline and enter again, and restart Presto, respectively.

----End

Component Access to OBS When OBS Permission Control Is Enabled

Step 1 Log in to any node in a cluster as user **root** using the password set during cluster creation.

Step 2 Set environment variables (The default client installation path is /opt/Bigdata/client. Configure the path based on site requirements.).

source /opt/Bigdata/client/bigdata_env

Step 3 If the Kerberos authentication is enabled for the current cluster, run the following command to authenticate the user. If the Kerberos authentication is disabled for the current cluster, skip this step:

kinit *MRS cluster user*

Example: **kinit admin**

Step 4 If the Kerberos authentication is disabled for the current cluster, run the following commands to log in. Note that you should create a user that belongs to the **supergroup** group by referring to **Creating a User** and replace *XXXX* with the username:

mkdir /home/XXXX

chown XXXX /home/XXXX

su - XXXX

Step 5 Access OBS. You do not need to configure the AK, SK, and endpoint. The OBS path format is **obs://buck_name/*XXX***.

Example: **hadoop fs -ls "obs://obs-example/job/hadoop-mapreduce-examples-3.1.2.jar"**

NOTE

- If you want to use **hadoop fs** to delete files on OBS, use **hadoop fs -rm -skipTrash** to delete the files.
- If data import is not involved when a table is created using spark-sql and spark-beeline, OBS will not be accessed. That is, if you create a table in an OBS directory on which you do not have permission, the **CREATE TABLE** operation will still be successful, but the error message "**403 AccessDeniedException**" is displayed when you insert data.

----End

Creating a Policy and an Agency on IAM

Step 1 Create a policy on IAM.

1. Log in to the IAM console.
2. Choose **Permissions**. On the displayed page, click **Create Custom Policy**.
3. Set parameters according to **Table 7-6**.

Table 7-6 Policy parameters

Parameter	Description
Policy Name	Only letters, digits, spaces, and special characters (-_.,) are allowed.
Scope	Select **Global services**, because OBS is a global service.
Policy View	Select **Visual editor**.
Policy Content	1. **Allow**: Select **Allow**. 2. **Select service**: Select **Object Storage Service (OBS)**. 3. **Select action**: Select **WriteOnly**, **ReadOnly**, and **ListOnly**. 4. **Specific resources**: a. Set **object** to **Specify resource path**, click **Add Resource Path**, and enter *obs_bucket_name*/**tmp/** and *obs_bucket_name*/**tmp/***. The **/tmp** directory is used as an example. If you need to add permissions for other directories, perform the following steps to add the directories and resource paths of all objects in the directories. b. Set **bucket** to **Specify resource path**, click **Add Resource Path**, and enter *obs_bucket_name*. 5. (Optional) Add request condition, which does not need to be added currently.
Description	(Optional) Brief description about the policy.

NOTE

If the data write operation of each component is implemented in **rename** mode, the permission to delete objects must be configured when data is written.

4. Click **OK** to save the policy.

Step 2 Create an agency on IAM.

1. Log in to the IAM console.
2. Choose **Agencies**. On the displayed page, click **Create Agency**.
3. Set parameters according to **Table 7-7**.

Table 7-7 Agency parameters

Parameter	Description
Agency Name	Only letters, digits, spaces, and special characters (-_.,) are allowed.
Agency Type	Select **Common account**.
Delegated Account	Enter your cloud account, that is, the account you register using your mobile phone number. It cannot be a federated user or an IAM user created using your cloud account.
Validity Period	Set this parameter as required.
Description	(Optional) Brief description about the agency.
Permissions	1. In the **Project [Region]** column, locate the row where **OBS** is, click **Attach Policy**. 2. Select the policy created in **Step 1** to display it in **Selected Policies**. 3. Click **OK**.

4. Click **OK** to save the agency.

NOTE

If you modify an agency and policies bound to it after using the agency to access OBS, the modification will take effect within 15 minutes.

----End

7.3 Interconnecting with OBS Using the Guardian Service

7.3.1 Scenarios

Configuring Storage and Compute Decoupling

1. Create an MRS cluster.

   The MRS cluster must contain basic components such as Guardian, Ranger, and Hadoop.

   NOTE

   Currently, only MRS 3.3.0-LTS and later versions support interconnection with OBS using the Guardian component.

2. Create an OBS agency.

   Create an agency with OBS access permissions, which is used for interconnecting Guardian with OBS.

3. Enable the interconnection between Guardian and OBS and configure parameters.

   Modify the configuration parameters for the Guardian service and configure the IAM agency authentication information.

4. Configure the policy for clearing component data in the recycle bin directory.

   In the storage-compute decoupling scenario, the prevention against accidental deletion is enabled by default for components connected to OBS. When a user deletes data, the deleted object is moved to the corresponding recycle bin directory. You need to configure a lifecycle rule for the corresponding directory in the OBS file system to prevent the storage space from being used up.

5. Interconnect components with OBS.

   Components in the MRS cluster can directly access the corresponding path after the required permissions for accessing OBS buckets are obtained. You can use the component client to directly access resources in the OBS file system in absolute path mode.

Configuring OBS Permissions

If Guardian is deployed with decoupled storage and compute and Ranger authentication is enabled for MRS clusters, Ranger administrators can configure read and write permissions on OBS directories or files for cluster users.

With the Guardian permission model, storage and compute decoupling, and Hive cascading authorization, authorization is not required after the first permission service table authorization on the Ranger page and the system automatically associates the permissions of OBS data storage source in a fine-grained manner. The storage path of the table does not need to be sensed.

NOTE

- On the Ranger page, OBS permission authorization only support Manager custom user groups (built-in user groups are not supported). The user group contains a maximum of 52 characters, including digits 0 to 9, letters A to Z, underscores (_), and number signs (#). Otherwise, the policy fails to be added.
- For clusters with Kerberos authentication enabled, permissions need to be granted based on Ranger. For clusters with Kerberos authentication disabled, OBS permissions are granted by default, and no additional configuration is required.
- If Kerberos authentication is not enabled for the current cluster, the user who accesses OBS must belong to the **supergroup** group.

7.3.2 Interconnecting the Guardian Service with OBS

Scenario

This section describes how to enable storage and compute decoupling for the Guardian component. After this feature is enabled, Guardian can provide temporary authentication credentials for services such as HDFS, Hive, Spark, Loader, and HetuEngine to access OBS when decoupled storage and compute are used.

Perform the following steps to interconnect Guardian with OBS:

1. **Creating an OBS Parallel File System**
2. **Creating a Cloud Service Agency and Binding It to a Cluster**
3. **Creating an Agency for a Regular Account**
4. **Configuring a Cloud Service Agency**
5. **Granting OBS Access Permission to Guardian**
6. **Enabling Cascading Authorization for Hive Tables**
7. **Configuring the Recycle Bin Cleanup Policy**

Prerequisites

- Components such as Guardian, Ranger, and Hadoop have been installed in the cluster.
- If Guardian is installed after components such as Hadoop, HetuEngine, Hive, and Spark are installed, the Guardian client must be downloaded again and the default client for job submission on the management plane must be refreshed.

Impact on the System

- After the configuration is complete, you need to refresh the configuration of the original client or reinstall the client.
- To submit a job on console, log in to the active OMS node as user **omm** and run the **sh /opt/executor/bin/refresh-client-config.sh** command to refresh the built-in client of the cluster.

Creating an OBS Parallel File System

1. Log in to the OBS console.

2. Choose **Parallel File Systems** > **Create Parallel File System**.
3. Enter a file system name, for example, **guardian-obs**.

   The name of an enterprise project must be the same as that of the MRS cluster. Set other parameters.
4. Click **Create Now**.

Creating a Cloud Service Agency and Binding It to a Cluster

1. Log in to the management console.
2. In the service list, choose **Management & Governance** > **Identity and Access Management**.
3. Choose **Agencies**. On the displayed page, click **Create Agency**.
4. Set the agency name, for example, **mrs_ecs_obs**.
5. Set **Agency Type** to **Cloud service** and select **Elastic Cloud Server (ECS) and Bare Metal Server (BMS)** to authorize ECS or BMS to invoke OBS.
6. Set **Validity Period** to **Unlimited** and click **Next**.
7. On the displayed page, search for the **OBS OperateAccess** policy and enable it.
8. Click **Next**, select **All resources**, click **Show More**, select **Global resources**, and click **OK**.
9. In the dialog box that is displayed, click **OK** to start authorization. After "**Authorization successful.**" is displayed, click **Finish**. The agency is successfully created.
10. Log in to the MRS console. In the navigation pane on the left, choose **Clusters** > **Active Clusters**.
11. Click the name of the target cluster to go to details page.
12. In the **Dashboard** tab, click **Synchronize** on the right of **IAM User Sync** to synchronize the IAM user.
13. In the **Dashboard** tab, click **Manage Agency** on the right of **Agency**, select the created agency, for example, **mrs_ecs_obs**, and click **OK** to bind the agency to the cluster.

Creating an Agency for a Regular Account

1. Log in to the management console.
2. In the service list, choose **Management & Governance** > **Identity and Access Management**.
3. Choose **Agencies**. On the displayed page, click **Create Agency**.
4. Enter an agency name, for example, **agency-MRS-to-OBS**.
5. Set **Agency Type** to **Account**.
6. Enter your cloud account for **Delegated Account**, that is, the account you register using your mobile phone number. It cannot be a federated user or an IAM user created using your cloud account.
7. Set **Validity Period** to **Unlimited** and click **Next**.
8. In the search box on the displayed page, search for **OBS Administrator** and select the policy.

9. Click **Next**. Select **All resources**, click **Show More**, select **Global resources**, and click **OK**.
10. After the agency is created, check and record the agency ID.

Configuring a Cloud Service Agency

1. Log in to the management console.
2. In the service list, choose **Management & Governance** > **Identity and Access Management**.
3. Select **Agencies** and click the agency **mrs_ecs_obs** created in **Creating a Cloud Service Agency and Binding It to a Cluster**
4. Choose **Permissions** > **Authorize**, click **Create Policy** in the upper right corner, and set the parameters as follows:
   - **Policy Name**: Enter a policy name, for example, **guardian-assume-policy**.
   - **Policy View**: Select **JSON**.
   - **Policy Content**: Configure the policy as follows. *{Agency ID}* indicates the ID recorded in **10**.

```
{
    "Version": "1.1",
    "Statement": [
        {
            "Action": [
                "iam:agencies:assume"
            ],
            "Resource": {
                "uri": [
                    "/iam/agencies/{Agency ID}"
                ]
            },
            "Effect": "Allow"
        }
    ]
}
```

5. Click **Next**. On the **Select Policy/Role** page, select the policy created in **4**.
6. Click **Next**, select **All resources**, click **Show More**, select **Global resources**, and click **OK**.

Granting OBS Access Permission to Guardian

1. Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Guardian**, click **Configurations**, and then **All Configurations**. On the displayed page, search for and modify the following parameters.

Parameter	Description	Value
fs.obs.guardian.accesslabel.enabled	Whether to enable **access label** for using Guardian to connect to OBS.	true
fs.obs.guardian.enabled	Whether to enable Guardian.	true

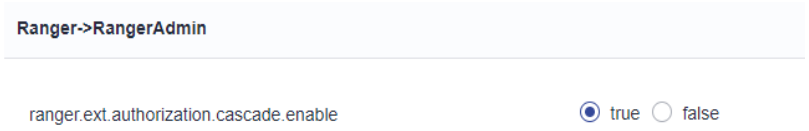
Parameter	Description	Value
fs.obs.delegation.token.providers	Delegation token generator. If **fs.obs.guardian.enabled** is set to **true**, configure both **com.xxx.mrs.dt.MRSDelegationTokenProvider** and **com.xxx.mrs.dt.GuardianDTProvider**.	com.xxx.mrs.dt.MRSDelegationTokenProvider and com.xxx.mrs.dt.GuardianDTProvider
token.server.access.label.agency.name	Name of the specified IAM agency, which is the agency created in **Creating an Agency for a Regular Account**.	agency-MRS-to-OBS

2. Save the service configuration, choose **More** > **Restart Configuration-Expired Instances** on the FusionInsight Manager home page, and restart all service instances whose configurations have expired as prompted.
3. To submit jobs on the MRS console, log in to the active OMS node as user **omm** and run the following command to refresh the built-in client configuration:

   sh /opt/executor/bin/refresh-client-config.sh

Enabling Cascading Authorization for Hive Tables

1. Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Ranger** and click **Configurations**.
2. Search for the **ranger.ext.authorization.cascade.enable** parameter and set it to **true**.



3. Click **Save**.
4. Click **Instance** and select all RangerAdmin instances. Click **More** and select **Restart Instance**. Enter the password, and click **OK** to restart all RangerAdmin instances.

Configuring the Recycle Bin Cleanup Policy

1. Log in to the OBS Console.
2. Select **Parallel File Systems** and click the file system created in **Creating an OBS Parallel File System**.
3. Choose **Basic Configurations** > **Lifecycle Rules** and click **Create** to create a lifecycle rule for the **/user/.Trash** directory.

CAUTION

For clusters that use decoupled storage and compute, configure a lifecycle policy for the related directories by referring to this chapter. Otherwise, the storage space may be used up and storage fees may increase.

Table 7-8 Parameters for creating a lifecycle rule

Parameter	Description	Example
Status	Whether to enable the lifecycle rule.	Enable
Rule Name	User-defined rule name, which is used to identify different lifecycle configurations.	rule-test
Prefix	Prefix of the objects to which the lifecycle rule applies. Generally, the recycle bin directory of MRS components is **/user/.Trash**.	user/.Trash
Transition to Infrequent Access After (Days)	Number of days before transitioning to infrequent access after the object is last updated. The value of this parameter must be at least **30**.	30 days
Transition to Archive After (Days)	Number of days before transitioning to archive after the object is last updated. If **Transition to Infrequent Access After (Days)** is also configured, after the lifecycle is transitioned to infrequent access, wait at least 30 days before transitioning it to archive. If only **Transition to Archive After (Days)** is configured, there is no time limit.	31 days
Delete Files After (Days)	Number of days before being deleted by OBS after the object is last updated. This parameter must be larger than the above two parameters.	32 days
Delete Fragments After (Days)	Number of days before fragments are expired and deleted by OBS automatically.	30 days

4. Click **OK** to complete the lifecycle rule configuration.

   To modify the lifecycle configuration, locate the lifecycle rule, click **Edit** or **Disable** on the right. Click **Enable** to enable the lifecycle rule.

7.3.3 Interconnecting Components with OBS Using Guardian

7.3.3.1 Interconnecting Hive with OBS

Interconnecting with OBS

MRS clusters allow Hive to connect to OBS through Metastore.

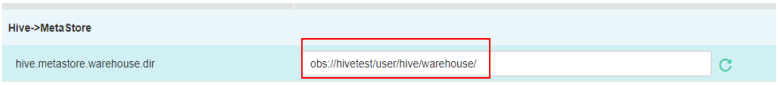
Interconnecting Hive with OBS through Metastore

Step 1 You have configured storage and compute decoupling by referring to **Interconnecting the Guardian Service with OBS**.

Step 2 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Hive**, and click **Configurations**.

Step 3 Search for **hive.metastore.warehouse.dir** in the search box and change the parameter value to an OBS path, for example, **obs://hivetest/user/hive/warehouse/**. **hivetest** indicates the OBS file system name.

Figure 7-22 hive.metastore.warehouse.dir configuration



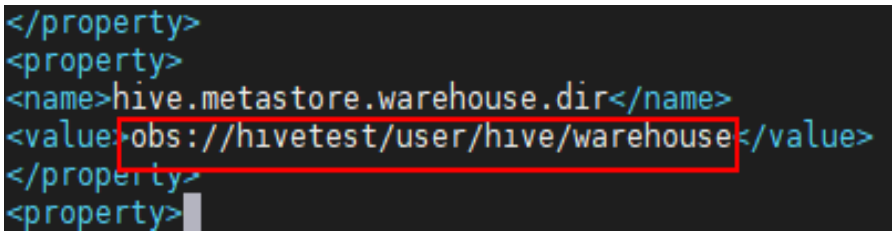
Step 4 Save the configuration, choose **Cluster** > **Services**, and restart the Hive service in the service list.

Step 5 Update the client configuration file.

1. Log in to the node where the Hive client is located and run the following command to modify **hivemetastore-site.xml** in the Hive client configuration file directory:

   vi *Client installation directory*/**Hive/config/hivemetastore-site.xml**

2. Change the value of **hive.metastore.warehouse.dir** to the corresponding OBS path, for example, **obs://hivetest/user/hive/warehouse/**.

3. Change the value of **hive.metastore.warehouse.dir** of **hivemetastore-site.xml** in the HCatalog client configuration file directory to the corresponding OBS path, for example, **obs://hivetest/user/hive/warehouse/**.

   vi *Client installation directory*/**Hive/HCatalog/conf/hivemetastore-site.xml**

Step 6 Go to the Hive Beeline CLI, create a database, and ensure that the location is an OBS path.

cd *Client installation directory*

kinit *Component operation user*

beeline

create database testdb1;

show create database testdb1;

```
+----------------------------------------------------+
|                   createdb_stmt                    |
+----------------------------------------------------+
| CREATE DATABASE `testdb1`                          |
| LOCATION                                           |
|   'obs://0417x86/user/hive/warehouse/testdb1.db'   |
+----------------------------------------------------+
```

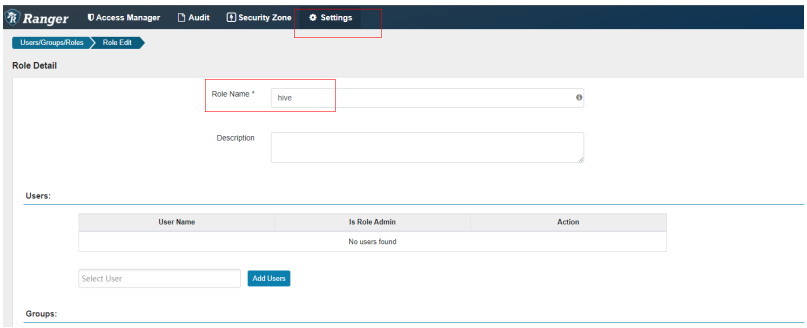
----End

Configuring Ranger Permissions

- Granting the read and write permissions on OBS paths to the **hive** user group
  a. Log in to the Ranger web UI as the Ranger administrator. On the home page, click component plug-in name **OBS** in the **EXTERNAL AUTHORIZATION** area, and assign the **Read** and **Write** permissions on the OBS storage path to the **hive** user group. If this operation is successful, all users in the **hive** group can access the Hive data warehouse path.

     For example, assign the **Read** and **Write** permissions on the **obs://hivetest/user/hive/warehouse/** directory to the **hive** user group:

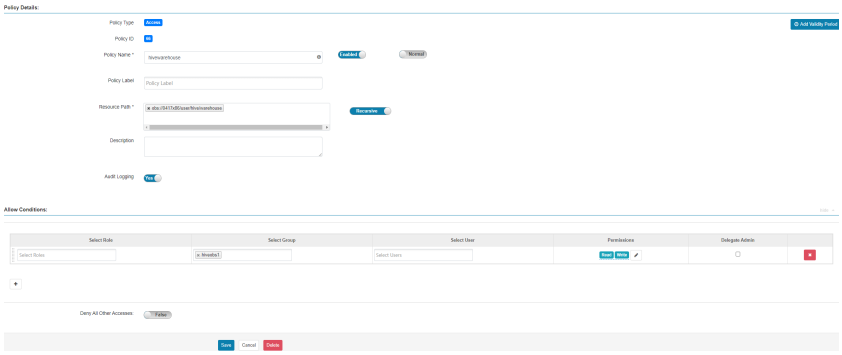
     
  b. Choose **Settings** > **Roles**, click **Add New Role**, and create a role whose **Role Name** is **hive**.

- Granting the read and write permissions on OBS paths to a custom user group
  a. Log in to FusionInsight Manager and choose **System** > **Permission** > **User Group**. On the displayed page, click **Create User Group**.
  b. Create a user group without a role, for example, **hiveobs1**, and bind the user group to the corresponding user.
  c. Log in to the Ranger management page as the **rangeradmin** user.

d. On the home page, click component plug-in name **OBS** in the **EXTERNAL AUTHORIZATION** area.

e. Grant the **Read** and **Write** permissions on the OBS storage path to the **hiveobs1** user group. In this case, all users bound to the **hiveobs1** user group can access the Hive data warehouse path.

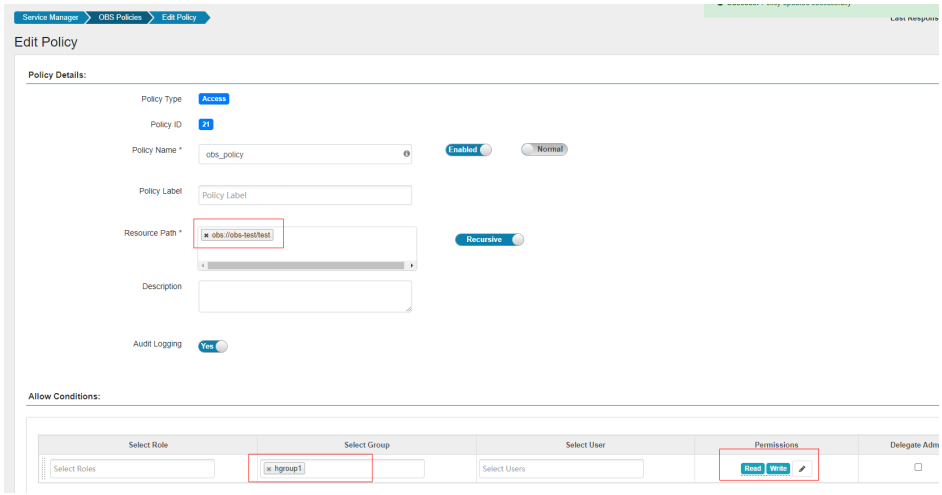


- Creating a database,table, or partition in a custom location and granting read and write permissions on OBS paths

a. Log in to the Ranger web UI as the Ranger administrator.

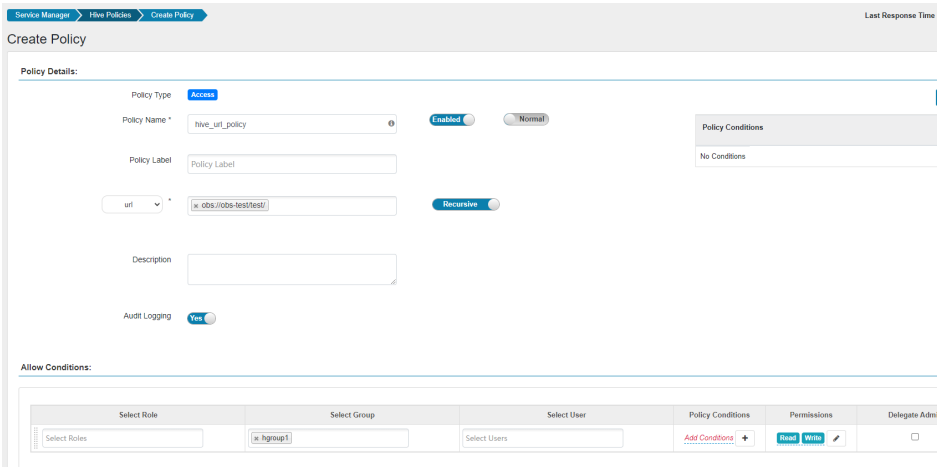
b. On the home page, click component plug-in name **OBS** in the **EXTERNAL AUTHORIZATION** area, and assign the **Read** and **Write** permissions on the OBS storage path to the user group of the corresponding user.

For example, assign the **Read** and **Write** permissions on the **obs://obs-test/test/** directory to the **hgroup1** user group, as shown in the following figure.



c. On the home page, click the component plug-in name **Hive** in the **HADOOP SQL** area, and add a URL policy that grants the **Read** and **Write** permissions on the OBS path to the user group of the corresponding user.

For example, create the **hive_url_policy URL** policy for the **hgroup1** user group and assign the **Read** and **Write** permissions on the **obs://obs-test/test/** directory to the user group, as shown in the following figure.



d. Log in to the beeline client and set **Location** to the OBS file system path when creating a table.

cd *Client installation directory*

kinit *Component operation user*

beeline

For example, to create a table named **test** whose **Location** is **obs://obs-test/test/***Database name*/*Table name*, run the following command:

create external table test(name string) location "obs://obs-test/test/*Database name*/*Table name*"**;**

NOTE

- To authorize a view chart, you need to grant the view chart permission and the physical table path permission corresponding to the view chart.
- Cascading authorization can be performed only on databases and tables, and cannot be on partitions. If a partition path is not in the table path, you need to manually authorize the partition path.
- Cascading authorization for **Deny Conditions** in the Hive Ranger policy is not supported. That is, the Deny Conditions permission only restricts the table permission and cannot generate the permission of the HDFS/OBS storage source.
- The permission of the HDFS Ranger policy is prior to that of the HDFS/OBS storage source generated by cascading authorization. If the HDFS Ranger permission has been set for the HDFS storage source of the table, the cascading permission does not take effect.
- **alter** operations cannot be performed on tables whose storage source is OBS after cascading authorization. To perform the **alter** operation, you need to grant the **Read** and **Write** permissions of the parent directory of the OBS table path to the corresponding user group.

7.3.3.2 Interconnecting Flink with OBS

Interconnecting with OBS

Step 1 Log in to the Flink client installation node as the client installation user.

Step 2 Run the following command to initialize environment variables:

source *Client installation directory*/**bigdata_env**

Step 3 Configure the Flink client.

Step 4 Start a session.

- Normal cluster (Kerberos authentication disabled)

  yarn-session.sh -nm "*session-name***" -d**

- Security cluster (Kerberos authentication enabled)
  - If the **flink.keystore** and **flink.truststore** file paths are relative paths:

    Run the following command in the directory at the same level as **ssl** to start the session. **ssl/** is a relative path.

    cd /opt/hadoopclient/Flink/flink/conf/

    yarn-session.sh -t ssl/ -nm "*session-name***" -d**

    ```
    ...
    Cluster started: Yarn cluster with application id application_1624937999496_0017
    JobManager Web Interface: http://192.168.1.150:32261
    ```

  - If the **flink.keystore** and **flink.truststore** file paths are absolute paths:

    Run the following command to start a session:

    cd /opt/hadoopclient/Flink/flink/conf/

    yarn-session.sh -nm "*session-name***" -d**

Step 5 For a security cluster, run the following command to perform user authentication. If Kerberos authentication is not enabled for the current cluster, you do not need to run this command.

kinit *Username*

Step 6 Explicitly add the OBS file system to be accessed in the Flink command line.

echo -e 'test' >/tmp/test

hdfs dfs -mkdir -p obs://*Parallel file system name***/tmp/flinkjob**

hdfs dfs -put /tmp/test/ obs://*Parallel file system name***/tmp/flinkjob/**

flink run Client installation directory**/Flink/flink/examples/batch/WordCount.jar -input obs://***Parallel file system name***/tmp/flinkjob/test -output obs://***Parallel file system name***/tmp/flinkjob/output**

----End

NOTE

- Flink jobs are running on Yarn. Before configuring Flink to interconnect with the OBS file system, ensure that the interconnection between Yarn and the OBS file system is normal.
- *Name of the OBS parallel file system/File name*: The OBS file path must be written to the directory level.
- If Kerberos authentication has been enabled (security mode) for the cluster, grant the **Read** and **Write** permissions on OBS paths to component users in Ranger by referring to **Ranger Permission Configuration**.

Ranger Permission Configuration

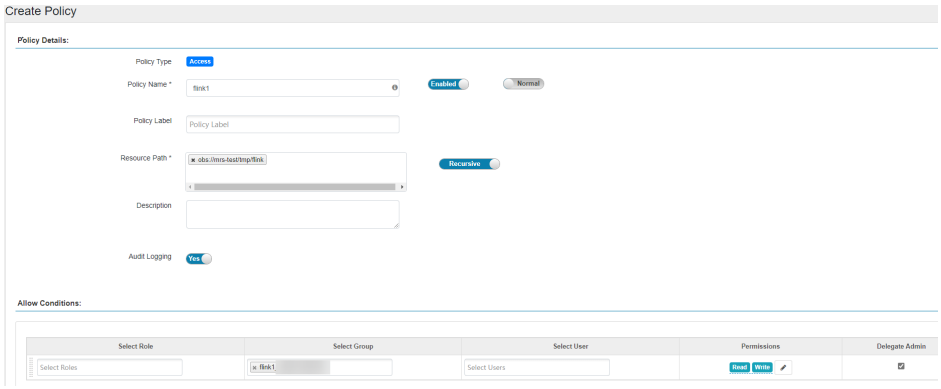
Step 1 Log in to FusionInsight Manager and choose **System** > **Permission** > **User Group**. On the displayed page, click **Create User Group**.

Step 2 Create a user group without a role, for example, **obs_flink**, and bind the user group to the corresponding user.

Step 3 Log in to the Ranger management page as the **rangeradmin** user.

Step 4 On the home page, click component plug-in name **OBS** in the **EXTERNAL AUTHORIZATION** area.

Step 5 Click **Add New Policy** to add the **Read** and **Write** permissions on OBS paths to the user group created in **Step 2**. If there are no OBS paths, create one in advance (wildcard character * is not allowed).



----End

7.3.3.3 Interconnecting Spark with OBS

Interconnecting with OBS

In an MRS cluster, **Location** can be set to an OBS file system path during Spark table creation and Spark can connect to OBS through Hive Metastore.

- Setting the location to an OBS path during table creation:
  a. Log in to the node where the client is installed as the client installation user and access the **spark-sql** client.

     cd *Client installation directory*

     kinit *Component operation user*

     spark-sql --master yarn

  b. Set **Location** to the OBS file system path when creating a table.

     For example, to create a table named **test** whose **Location** is **obs://obs-test/test/***Database name***/***Table name*, run the following command:

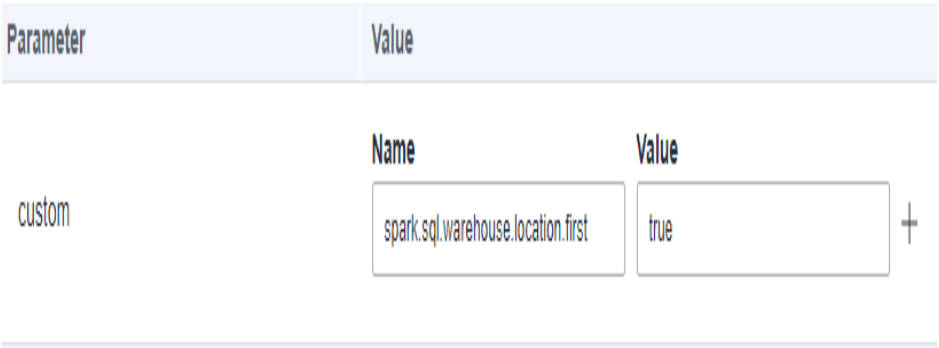
     create external table testspark(name string) location "obs://obs-test/test/*Database name***/***Table name***";**
- Interconnecting Spark with OBS through Hive Metastore:
  a. Complete the configurations by referring to **Interconnecting Hive with OBS using MetaStore**.
  b. Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Spark** and choose **Configurations** > **All Configurations**.

c. In the navigation pane on the left, choose **SparkResource** > **Customization**. In the custom configuration items, add **spark.sql.warehouse.location.first** to the **custom** parameter and set its value to **true**.

Figure 7-23 spark.sql.warehouse.location.first configuration

d. In the navigation pane on the left, choose **JDBCServer** > **Customization**. In the custom configuration items, add **spark.sql.warehouse.location.first** to the **custom** parameter and set its value to **true**.

Figure 7-24 spark.sql.warehouse.location.first configuration



e. Click **Save** to save the configuration. Click the **Dashboard** tab choose **More** > **Restart Service**, enter the password, click **OK**, and click **OK** again to restart Spark.

f. After Spark is restarted, choose **More** > **Download Client** to download and install the Spark client again. Then, go to **g**.

If you do not download and install the client again, you can perform the following steps to update the Spark client configuration file (assume that the client directory is **/opt/client**):

i. Log in to the node where the Spark client is deployed as user **root** and switch to the client installation directory.

cd /opt/client

ii. Run the following command to modify **hive-site.xml** in the configuration file directory of the Spark client:

vi Spark/spark/conf/hive-site.xml

Change the value of **hive.metastore.warehouse.dir** to the corresponding OBS path, for example, **obs://hivetest/user/hive/warehouse/**.

```
<property>
<name>hive.metastore.warehouse.dir</name>
<value>obs://hivetest/user/hive/warehouse/<value>
</property>
```

iii. Run the following command to modify the **spark-defaults.conf** file in the configuration file directory of the Spark client and set **spark.sql.warehouse.location.first** to **true**:

vi Spark/spark/conf/spark-defaults.conf

g. Configure the OBS directory permission for the component operation user in clusters with Kerberos authentication enabled by referring to **Configuring Ranger Permissions**.

h. Go to the SparkSQL CLI and spark-beeline, create a table, and check whether the location of the table is an OBS path.

source bigdata_env

kinit *Service user* (skip this step for normal clusters)

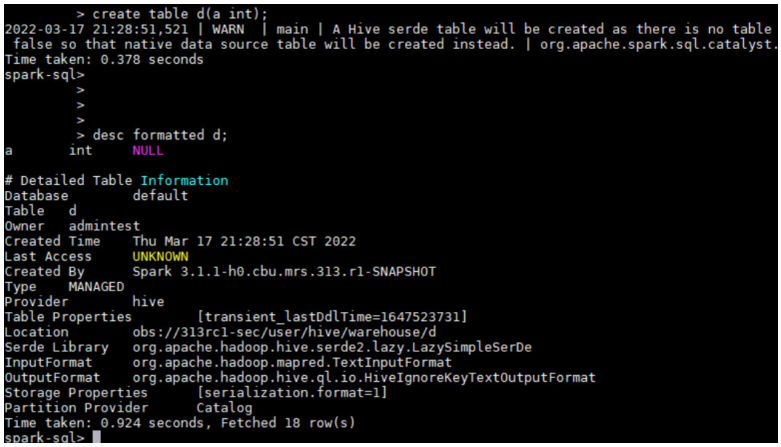
- Go to the SparkSQL CLI.

  spark-sql

  create table *d*(**a int**);

  desc formatted *d*;

  As shown in the following figure, the location of table **d** is in the specified OBS path.



- Go to spark-beeline.

  spark-beeline

  create table *e*(**a int**);

  desc formatted *e*;

  As shown in the following figure, the location of table **e** is in the specified OBS path.

```
0: jdbc:hive2://BMS-ARM-node-master3Xxky:22550/> create table e(a int) ;
+---------+
| Result  |
+---------+
+---------+
No rows selected (0.763 seconds)
0: jdbc:hive2://BMS-ARM-node-master3Xxky:22550/> desc formatted e;
+-------------------------------+----------------------------------------------------+----------+
|           col_name            |                     data_type                      | comment  |
+-------------------------------+----------------------------------------------------+----------+
| a                             | int                                                | NULL     |
|                               |                                                    |          |
| # Detailed Table Information  |                                                    |          |
| Database                      | default                                            |          |
| Table                         | e                                                  |          |
| Owner                         | admintest                                          |          |

18 rows selected (1.418 seconds)
```

Configuring Ranger Permissions

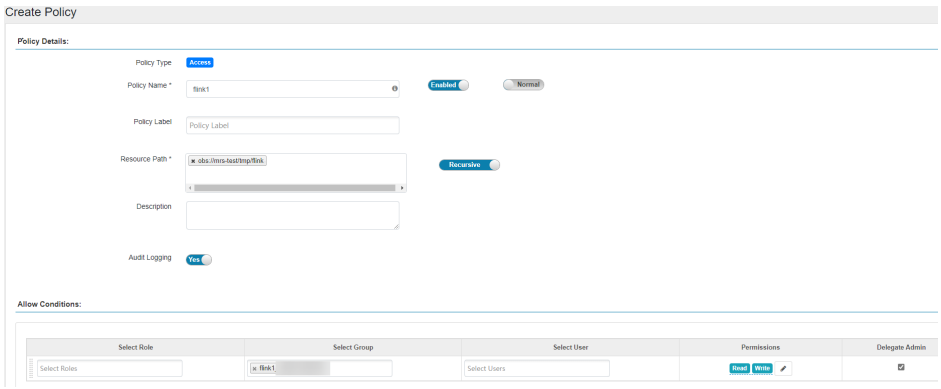
Step 1 Log in to FusionInsight Manager and choose **System** > **Permission** > **User Group**. On the displayed page, click **Create User Group**.

Step 2 Create a user group without a role, for example, **obs_spark**, and bind the user group to the corresponding user.

Step 3 Log in to the Ranger management page as the **rangeradmin** user.

Step 4 On the home page, click component plug-in name **OBS** in the **EXTERNAL AUTHORIZATION** area.

Step 5 Click **Add New Policy** to add the **Read** and **Write** permissions on OBS paths to the user group created in **Step 2**. If there are no OBS paths, create one in advance (wildcard character * is not allowed).



----End

NOTE

- Cascading authorization is not supported for view tables.
- Cascading authorization can be performed only on databases and tables, and cannot be on partitions. If a partition path is not in the table path, you need to manually authorize the partition path.
- Cascading authorization for Deny Conditions in the Hive Ranger policy is not supported. That is, the Deny Conditions permission only restricts the table permission and cannot generate the permission of the HDFS storage source.
- The permission of the HDFS Ranger policy is prior to that of the HDFS storage source generated by cascading authorization. If the HDFS Ranger permission has been set for the HDFS storage source of the table, the cascading permission does not take effect.

Configuring Permissions for CDL Service Users

If Kerberos authentication is enabled for the cluster (the cluster is in security mode) and you need to store real-time data to OBS after the interconnection, perform the following operations to grant the **Read** and **Write** permissions on the corresponding OBS path to the specific user:

Step 1 Log in to FusionInsight Manager and choose **System** > **Permission** > **User Group**. On the displayed page, click **Create User Group**.

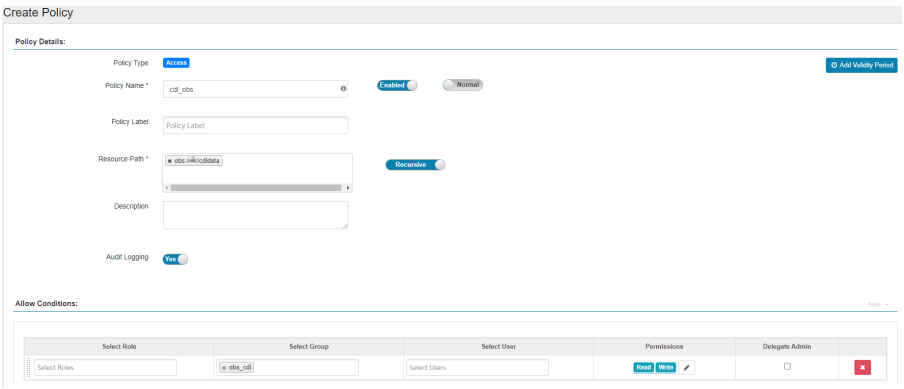
Step 2 Create a user group without a role, for example, **obs_cdl**, and bind the user group to the corresponding CDL service user, for example, **cdluser**.

Step 3 Log in to the Ranger management page as the **rangeradmin** user.

Step 4 On the home page, click component plug-in name **OBS** in the **EXTERNAL AUTHORIZATION** area.

Step 5 Click **Add New Policy** to add the **Read** and **Write** permissions on OBS paths to the created user group. If there are no OBS paths, create one in advance (wildcard character * is not allowed).

The following figure shows the configurations needed for adding the **Read** and **Write** permissions on **obs://***OBS parallel file system name***/cdldata** to user group **obs_cdl**.



----End

7.3.3.4 Interconnecting Hudi with OBS

Interconnecting with OBS

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following commands to configure environment variables:

source*Client installation directory***/bigdata_env**

source *Client installation directory***/Hudi/component_env**

Step 3 Modify the configuration file.

vim *Client installation directory***/Hudi/hudi/conf/hdfs-site.xml**

```
<property>
<name>dfs.namenode.acls.enabled</name>
<value>false</value>
</property>
```

Step 4 If Kerberos authentication has been enabled(security mode) for the cluster, run the following command to perform authentication as a user who has the Read and Write permissions on the corresponding OBS path. If Kerberos authentication has not been enabled (normal mode) for the cluster, you do not need to run this command.

kinit *Username*

Step 5 Start **spark-shell** and run the following commands to create a COW table and store it to OBS:

spark-shell --master yarn

import org.apache.hudi.QuickstartUtils._

import scala.collection.JavaConversions._

import org.apache.spark.sql.SaveMode._

import org.apache.hudi.DataSourceReadOptions._

import org.apache.hudi.DataSourceWriteOptions._

import org.apache.hudi.config.HoodieWriteConfig._

val tableName = "hudi_cow_table"

val basePath = "obs://testhudi/cow_table/"

val dataGen = new DataGenerator

val inserts = convertToStringList(dataGen.generateInserts(10))

val df = spark.read.json(spark.sparkContext.parallelize(inserts, 2))

df.write.format("org.apache.hudi").

options(getQuickstartWriteConfigs).

option(PRECOMBINE_FIELD_OPT_KEY, "ts").

option(RECORDKEY_FIELD_OPT_KEY, "uuid").

option(PARTITIONPATH_FIELD_OPT_KEY, "partitionpath").

option(TABLE_NAME, tableName).

mode(Overwrite).

save(basePath);

NOTE

"obs://testhudi/cow_table/" is the OBS path, and **testhudi** is the name of the OBS parallel system file. Change them based on site requirements.

Step 6 Use DataSource to check whether the table is created and whether the data is normal.

val roViewDF = spark.

read.

format("org.apache.hudi").

load(basePath + "/*/*/*/*")

roViewDF.createOrReplaceTempView("hudi_ro_table")

spark.sql("select * from hudi_ro_table").show()

Step 7 Run the **:q** command to exit the **spark-shell** CLI.

----End

Configuring Ranger Permissions

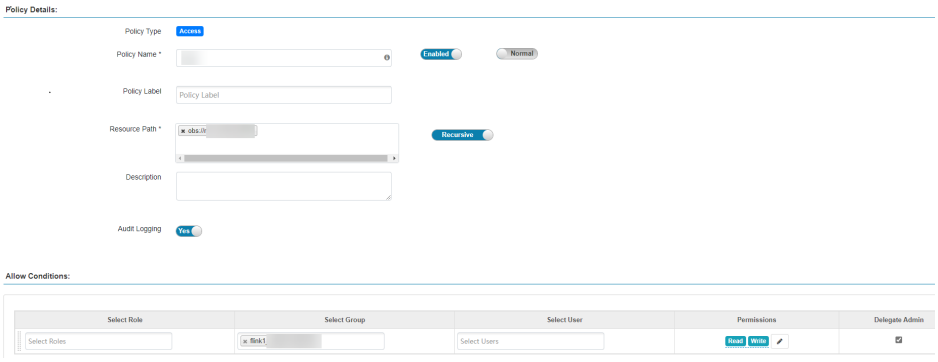
Step 1 Log in to FusionInsight Manager and choose **System** > **Permission** > **User Group**. On the displayed page, click **Create User Group**.

Step 2 Create a user group without a role, for example, **obs_hudi**, and bind the user group to the corresponding user.

Step 3 Log in to the Ranger management page as the **rangeradmin** user.

Step 4 On the home page, click component plug-in name **OBS** in the **EXTERNAL AUTHORIZATION** area.

Step 5 Click **Add New Policy** to add the **Read** and **Write** permissions on OBS paths to the user group created in **Step 2**. If there are no OBS paths, create one in advance (wildcard character * is not allowed).



----End

7.3.3.5 Interconnecting HetuEngine with OBS

Interconnecting with OBS

In an MRS cluster, **Location** can be set to an OBS file system path during HetuEngine table creation and HetuEngine can connect to OBS through Hive Metastore.

- Setting **Location** to the OBS file system path when creating a table
  a. If a HetuEngine compute instance is running, restart it.

     Log in to FusionInsight Manager as a user who has permission to access the HetuEngine web UI. Choose **Cluster** > **Services** > **HetuEngine**. In the **Basic Information** area in the Dashboard tab, click the link next to **HSConsole WebUI**. On the displayed HSConsole page, click **Compute Instance**. In the instance list, click **Restart** in the **Operation** column and operate as prompted.

  b. Log in to the node where the HetuEngine service client is located as the client installation user and run the following command:

     source *Client installation directory*/**bigdata_env**

  c. Log in to the HetuEngine client based on the cluster authentication mode.

     - Kerberos authentication has been enabled for the cluster (security mode): Run the following command to complete user authentication and log in to the HetuEngine client:

       kinit *User performing HetuEngine operations*

       hetu-cli --catalog hive --tenant default --schema default

       For details about how to assign permissions to users in the Ranger, see **Configuring Ranger Permissions**.

     - Kerberos authentication is not enabled for the cluster (normal mode): Run the following command to log in to the HetuEngine client:

       hetu-cli --catalog hive --tenant default --schema default --user *User performing HetuEngine operations*

  d. Set **Location** to the OBS file system path when creating a table.

create table test(name string) with (location = 'obs://*Name of the OBS parallel file system***/user/hive/warehouse/test');**

- Interconnecting with OBS through Hive Metastore
  a. Complete the configurations by referring to **Interconnecting Hive with OBS using MetaStore**.
  b. Log in to FusionInsight Manager, choose **Cluster** > **Services** > **HetuEngine**. On the displayed page, choose **More** > **Synchronize Configuration**. After the synchronization is complete, choose **More** > **Synchronize Configuration** again and then restart the HetuEngine service as prompted.

  NOTICE

  If a HetuEngine compute instance is running, stop it before restarting the service. After the service is restarted, start this compute instance.

  c. No location needs to be specified when you log in to the HetuEngine client to create a schema or table. The schema or table is stored on OBS by default.

Configuring Ranger Permissions

For HetuEngine clusters with Kerberos authentication enabled (security mode), the methods to grant Ranger permission are the same for both storage-compute decoupled architecture and and storage-compute coupled architecture.

7.3.3.6 Interconnecting HDFS with OBS

Interconnecting with OBS

Step 1 Log in to the node on which the HDFS client is installed as a client installation user.

Step 2 Run the following command to switch to the client installation directory:

cd *Client installation directory*

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If the cluster is in security mode, run the following command to authenticate the user. The user must have the read and write permissions on the OBS directory. Skip user authentication for normal clusters.

kinit *User performing HDFS operations*

Step 5 Explicitly add the OBS file system to be accessed in the HDFS command line.

The following commands are examples.

- Access the OBS file system.
  hdfs dfs -ls obs://*OBS parallel file system name*/*Path*

- Create a directory in the OBS file system.

  hdfs dfs -mkdir obs://*OBS parallel file system name/hadoop*
- Upload the **/opt/test.txt** file on the client node to the **obs://***OBS parallel file system name***/hadoop** directory.

  hdfs dfs -put /opt/test.txt obs://*OBS parallel file system name***/hadoop**

----End

NOTE

If a large number of logs are printed in the OBS file system, the read and write performance may be affected. You can adjust the log level of the OBS client as follows:

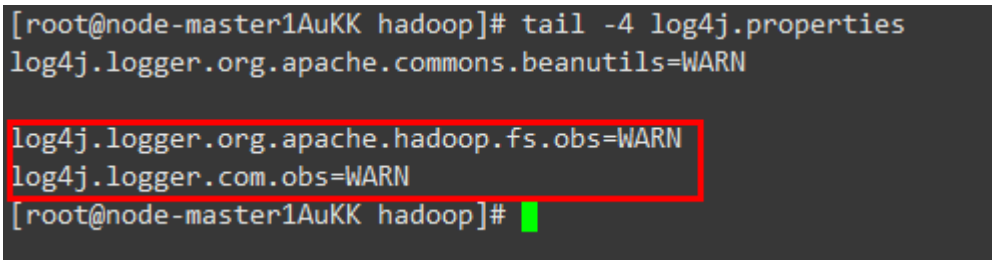
cd *Client installation directory***/HDFS/hadoop/etc/hadoop**

vi log4j.properties

Add the OBS log level configuration to the file as follows:

log4j.logger.org.apache.hadoop.fs.obs=WARN

log4j.logger.com.obs=WARN



Configuring Ranger Permissions

Step 1 Log in to FusionInsight Manager and choose **System** > **Permission** > **User Group**. On the displayed page, click **Create User Group** to create a user group without any roles, for example, **obs_hadoop**.

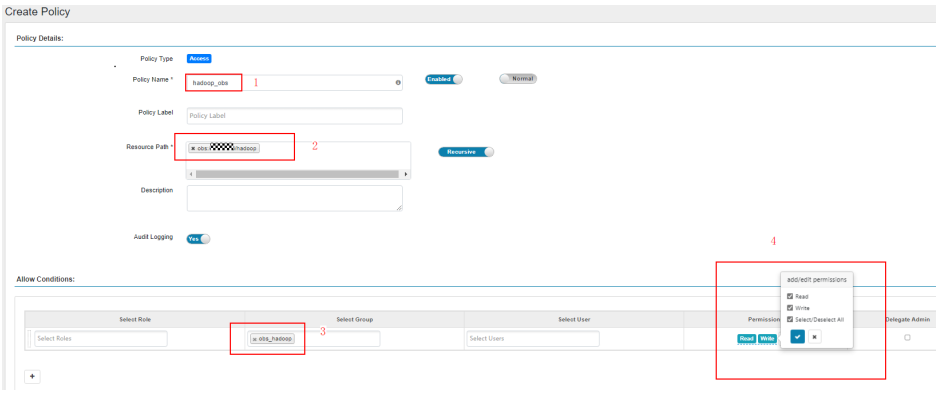
Step 2 Back to FusionInsight Manager and choose **System** > **Permission** > **User**. On the displayed page, click **Create User** to create a user that is associated only with the **obs_hadoop** user group, for example, **hadoopuser**.

Step 3 Log in to the Ranger management page as the **rangeradmin** user.

Step 4 On the home page, click component plug-in name **OBS** in the **EXTERNAL AUTHORIZATION** area.

Step 5 Click **Add New Policy** and add the **Read** and **Write** permissions on the desired OBS paths to the created user group.

The following figure shows the configurations needed for adding the **Read** and **Write** permissions on **obs://***OBS parallel file system name***/hadoop** to user group **obs_hadoop**.



----End

7.3.3.7 Interconnecting Yarn with OBS

Interconnecting with OBS

Step 1 Log in to the node on which the Yarn client is installed as a client installation user.

Step 2 Run the following command to switch to the client installation directory.

cd *Client installation directory*

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If the cluster is in security mode, run the following command to authenticate the user. The user must have the read and write permissions on the OBS directory. Skip user authentication for normal clusters.

kinit *User performing HDFS operations*

Step 5 Explicitly add the OBS file system to be accessed in the Yarn command line.

- Access the OBS file system.

  hdfs dfs -ls obs://*OBS parallel file system name***/***Path*

- Create a directory in the OBS file system.

  hdfs dfs -mkdir obs://*OBS parallel file system name/hadoop1*

- Execute the Yarn task to access OBS.

  yarn jar *Client installation directory***/HDFS/hadoop/share/hadoop/mapreduce/hadoop-mapreduce-examples-*.jar pi -Dmapreduce.job.hdfs-servers=NAMESERVICE -fs obs://***OBS parallel file system name* **1 1**

NAMESERVICE indicates the NameService in HDFS. The default value is **hdfs://hacluster**. If there are multiple NameServices, separate them with **,**.

The following command is an example:

yarn jar /opt/hadoopclient/HDFS/hadoop/share/hadoop/mapreduce/hadoop-mapreduce-examples-*.jar pi -Dmapreduce.job.hdfs-servers=hdfs://hacluster -fs obs://bucketname 1 1

- Run the following command to write data to OBS:

yarn jar *Client installation directory*/**HDFS/hadoop/share/hadoop/mapreduce/hadoop-mapreduce-examples-*.jar teragen 100 obs://***OBS parallel file system name***/hadoop1/teragen1**

- Run the following command to copy data from OBS to HDFS:

  hadoop distcp obs://*OBS parallel file system name***/hadoop1/teragen1 /tmp**

----End

NOTE

If a large number of logs are printed in the OBS file system, the read and write performance may be affected. You can adjust the log level of the OBS client as follows:

cd *Client installation directory*/**Yarn/config**

vi log4j.properties

Add the OBS log level configuration to the file. (If an application uses the built-in **log4j.properties** file, add the same configuration.)

log4j.logger.org.apache.hadoop.fs.obs=WARN

log4j.logger.com.obs=WARN

```
[root@node-master1AuKK config]# tail -4 log4j.properties
log4j.logger.org.apache.commons.beanutils=WARN

log4j.logger.org.apache.hadoop.fs.obs=WARN
log4j.logger.com.obs=WARN
[root@node-master1AuKK config]#
```

Configuring Ranger Permissions

Step 1 Log in to FusionInsight Manager and choose **System** > **Permission** > **User Group**. On the displayed page, click **Create User Group** to create a user group without any roles, for example, **obs_hadoop1**.

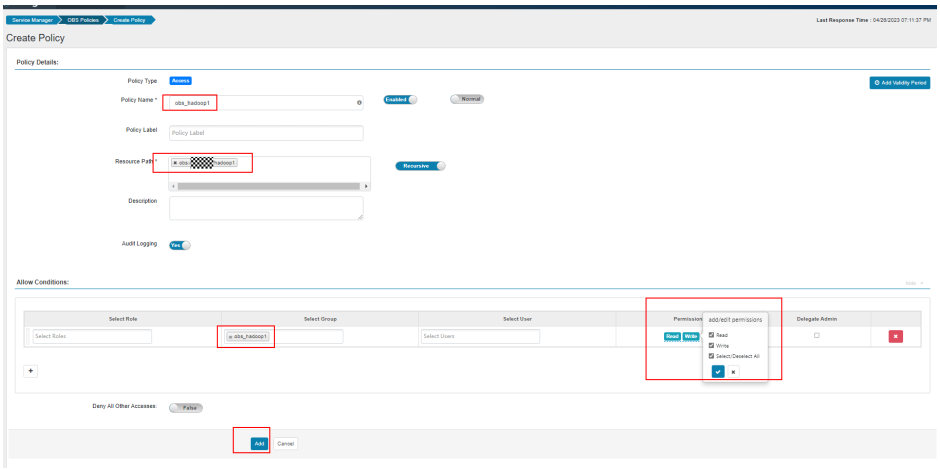
Step 2 Back to FusionInsight Manager and choose **System** > **Permission** > **User**. On the displayed page, click **Create User** to create a user that is associated with the **obs_hadoop1** user group and the **default** role, for example, **hadoopuser1**.

Step 3 Log in to the Ranger management page as the **rangeradmin** user.

Step 4 On the home page, click component plug-in name **OBS** in the **EXTERNAL AUTHORIZATION** area.

Step 5 Click **Add New Policy** and add the **Read** and **Write** permissions on the desired OBS paths to the user group created in **Step 1**.

The following figure shows the configurations needed for adding the **Read** and **Write** permissions on **obs://***OBS parallel file system name***/hadoop1** to user group **obs_hadoop1**.



----End

7.3.3.8 Interconnecting MapReduce with OBS

Interconnecting with OBS

Step 1 Log in to FusionInsight Manager, choose **Cluster** > **Services** > **MapReduce** and choose **Configurations** > **All Configurations**. In the navigation tree, choose **MapReduce** > **Customization**. In the customized configuration items, add the configuration item **mapreduce.jobhistory.always-scan-user-dir** to **core-site.xml** and set the parameter to **true**.

Step 2 Save the configurations and restart the MapReduce service.

----End

8 Accessing Web Pages of Open Source Components Managed in MRS Clusters

8.1 Web UIs of Open Source Components

Scenario

Web UIs of different components are created and hosted on the Master or Core nodes in the MRS cluster by default. You can view information about the components on these web UIs.

Procedure for accessing the web UIs of open-source component:

1. Select an access method.

   MRS provides the following methods for accessing the web UIs of open-source components:

   - **EIP-based Access**: This method is recommended because it is easy to bind an EIP to a cluster.
   - **Access Using a Windows ECS**: Independent ECSs need to be created and configured.
   - **Creating an SSH Channel for Connecting to an MRS Cluster and Configuring the Browser**: Use this method when the user and the MRS cluster are on different networks.

2. Access the web UIs. For details, see **Table 8-1**.

Web UIs

NOTE

For clusters with Kerberos authentication enabled, user **admin** does not have the management permission on each component. To access the web UI of each component, create a user who has the management permission on the corresponding component.

Table 8-1 Web UI addresses of open-source components

Cluster Type	Web UI Type	Web UI Address
All Types	Manager	For details, see **Accessing FusionInsight Manager**.
Custom	HDFS NameNode	On the Manager homepage, choose **Cluster** > **Services** > **HDFS** > **NameNode Web UI** > **NameNode (*Host name*, Active)**.
	HBase HMaster	On the Manager homepage, choose **Cluster** > **Services** > **HBase** > **HMaster Web UI** > **HMaster (*Host name*, Active)**.
	MapReduce JobHistoryServer	On the Manager homepage, choose **Cluster** > **Services** > **MapReduce** > **JobHistoryServer Web UI** > **JobHistoryServer (*Host name*, Active)**.
	YARN ResourceManager	On the Manager homepage, choose **Cluster** > **Services** > **Yarn** > **ResourceManager Web UI** > **ResourceManager (*Host name*, Active)**.
	Spark2x JobHistory	On the Manager homepage, choose **Cluster** > **Services** > **Spark2x** > **Spark2x Web UI** > **JobHistory2x (*Host name*)**.
	Hue	On the Manager homepage, choose **Cluster** > **Services** > **Hue** > **Hue Web UI** > **Hue (*Host name*, Active)**. Loader is a graphical data migration management tool based on the open-source Sqoop web UI, and its interface is hosted on the Hue web UI.
	Tez	On the Manager homepage, choose **Cluster** > **Services** > **Tez** > **Tez Web UI** > **TezUI (*Host name*)**.
	Storm	On the Manager homepage, choose **Cluster** > **Services** > **Storm** > **Storm Web UI** > **UI (*Host name*)**.
	Ranger	On the Manager homepage, choose **Cluster** > **Services** > **Ranger** > **Ranger Web UI** > **RangerAdmin**.

8.2 Common Ports of Components

Scenario

When you **buy a custom cluster** of an LTS version, you can customize the component port. If you do not want to customize a port, an open source port is used.

- **Open source**: Find the default port of the component in the Default Open Source Port column of the following table.
- **Custom**: Find the default port of the component in the Default Custom Port column of the following table.
- If there is only the Default Port column, the open source port of the component is the same as the default custom port.

If the cluster is not of an LTS version, the **Component Port** parameter is unavailable and only an open source port can be used. For details, see the Default Open Source Port or Default Port column.

Common HBase Ports

The protocol type of all ports in the table is TCP.

Parameter	Default Open Source Port	Default Custom Port	Port Description
hbase.master.port	16000	21300	HMaster RPC port. This port is used to connect the HBase client to HMaster. **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. • Is the port enabled by default during the installation: Yes • Is the port enabled after security hardening: Yes

Parameter	Default Open Source Port	Default Custom Port	Port Description
hbase.master.info.port	16010	21301	HMaster HTTPS port. This port is used by the remote web client to connect to the HMaster UI. **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. • Is the port enabled by default during the installation: Yes • Is the port enabled after security hardening: Yes
hbase.regionserver.port	16020	21302	RegoinServer (RS) RPC port. This port is used to connect the HBase client to RegionServer. **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. • Is the port enabled by default during the installation: Yes • Is the port enabled after security hardening: Yes
hbase.regionserver.info.port	16030	21303	HTTPS port of the Region server. This port is used by the remote web client to connect to the RegionServer UI. **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. • Is the port enabled by default during the installation: Yes • Is the port enabled after security hardening: Yes

Parameter	Default Open Source Port	Default Custom Port	Port Description
hbase.thrift.info.port	9095	21304	Thrift Server listening port of Thrift Server This port is used for: Listening when the client is connected **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. • Is the port enabled by default during the installation: Yes • Is the port enabled after security hardening: Yes
hbase.regionserver.thrift.port	9090	21305	Thrift Server listening port of RegionServer This port is used for: Listening when the client is connected to the RegionServer **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. • Is the port enabled by default during the installation: Yes • Is the port enabled after security hardening: Yes
hbase.rest.info.port	8085	21308	Port of the RegionServer RESTServer native web page
-	21309	21309	REST port of RegionServer RESTServer

Common HDFS Ports

The protocol type of all ports in the table is TCP.

Parameter	Default Open Source Port	Default Custom Port	Port Description
dfs.namenode.rpc.port	8020	25000	NameNode RPC port This port is used for: 1. Communication between the HDFS client and NameNode 2. Connection between the DataNode and NameNode **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
dfs.namenode.http.port	9870	25002	HDFS HTTP port (NameNode) This port is used for: 1. Point-to-point NameNode checkpoint operations 2. Connecting the remote web client to the NameNode UI **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes

Parameter	Default Open Source Port	Default Custom Port	Port Description
dfs.namenode.https.port	9871	25003	HDFS HTTPS port (NameNode) This port is used for: 1. Point-to-point NameNode checkpoint operations 2. Connecting the remote web client to the NameNode UI **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
dfs.datanode.ipc.port	9867	25008	IPC server port of DataNode This port is used for: Connection between the client and DataNode to perform RPC operations. **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
dfs.datanode.port	9866	25009	DataNode data transmission port This port is used for: 1. Transmitting data from HDFS client from or to the DataNode 2. Point-to-point DataNode data transmission **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes

Parameter	Default Open Source Port	Default Custom Port	Port Description
dfs.datanode.http.port	9864	25010	DataNode HTTP port This port is used for: Connecting to the DataNode from the remote web client in security mode **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
dfs.datanode.https.port	9865	25011	HTTPS port of DataNode This port is used for: Connecting to the DataNode from the remote web client in security mode **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
dfs.JournalNode.rpc.port	8485	25012	RPC port of JournalNode This port is used for: Client communication to access multiple types of information **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes

Parameter	Default Open Source Port	Default Custom Port	Port Description
dfs.journalnode.http.port	8480	25013	JournalNode HTTP port This port is used for: Connecting to the JournalNode from the remote web client in security mode **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
dfs.journalnode.https.port	8481	25014	HTTPS port of JournalNode This port is used for: Connecting to the JournalNode from the remote web client in security mode **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
httpfs.http.port	14000	25018	Listening port of the HttpFS HTTP server This port is used for: Connecting to the HttpFS from the remote REST API **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes

Common HetuEngine Ports

The protocol type of the port in the table is TCP.

Parameter	Default Open Source Port	Default Custom Port	Port Description
server.port (HSBroker)	29860	29860	Specifies the port number that HSBroker listens to.
server.port (HSConsole)	29880	29880	Specifies the port number that HSConsole listens to.
server.port (HSFabric)	29900	29900	Specifies the port number that HSFabric listens to, which is used for cross-domain connections
gateway.port	29902	29902	Specifies the port number that HSFabric listens to, which is used for JDBC connections

Common Hive Ports

The protocol type of all ports in the table is TCP.

Parameter	Default Open Source Port	Default Custom Port	Port Description
templeton.port	9111	21055	Port used for WebHCat to provide the REST service This port is used for: Communication between the WebHCat client and WebHCat server • Is the port enabled by default during the installation: Yes • Is the port enabled after security hardening: Yes

Parameter	Default Open Source Port	Default Custom Port	Port Description
hive.server2.thrift.port	10000	21066	Port for HiveServer to provide Thrift services This port is used for: Communication between the HiveServer and HiveServer client ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
hive.metastore.port	9083	21088	Port for MetaStore to provide Thrift services This port is used for: Communication between the MetaStore client and MetaStore, that is, communication between HiveServer and MetaStore. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
hive.server2.webui.port	10002	-	Web UI port of Hive This port is used for: HTTPS/HTTP communication between Web requests and the Hive UI server

Common Hue Ports

The protocol type of all ports in the table is TCP.

Parameter	Default Open Source Port	Default Custom Port	Port Description
HTTP_PORT	8888	21200	Port for Hue to provide HTTPS services This port is used to provide web services in HTTPS mode, which can be changed. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes

Common Kafka Ports

The protocol type of all ports in the table is TCP.

Parameter	Default Open Source Port	Default Custom Port	Port Description
port	9092	21005	Port for a broker to receive data and obtain services
ssl.port	9093	21008	SSL port used by a broker to receive data and obtain services
sasl.port	21007	21007	SASL security authentication port provided by a broker, which provides the secure Kafka service
sasl-ssl.port	21009	21009	Port used by a broker to provide encrypted service based on the SASL and SSL protocols

Common Loader Ports

The protocol type of all ports in the table is TCP.

Parameter	Default Port	Port Description
LOADER_HTTPS_PORT	21351	This port is used to provide REST APIs for configuration and running of Loader jobs. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes

Common MapReduce Ports

The protocol type of all ports in the table is TCP.

Parameter	Default Open Source Port	Default Custom Port	Port Description
mapreduce.jobhistory.webapp.port	19888	26012	Web HTTP port of the JobHistory server This port is used for: viewing the web page of the JobHistory server **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
mapreduce.jobhistory.port	10020	26013	Port of the JobHistory server This port is used for: 1. Task data restoration in the MapReduce client 2. Obtaining task report in the Job client **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
mapreduce.jobhistory.webapp.https.port	19890	26014	Web HTTPS port of the JobHistory server This port is used to view the web page of the JobHistory server. **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes

Common Spark Ports

The protocol type of all ports in the table is TCP.

Parameter	Default Open Source Port	Default Custom Port	Port Description
hive.server2.thrift.port	22550	22550	JDBC thrift port This port is used for: Socket communication between Spark2.1.0 CLI/JDBC client and server **NOTE** If **hive.server2.thrift.port** is occupied, an exception indicating that the port is occupied is reported. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
spark.ui.port	4040	22950	Web UI port of JDBC This port is used for: HTTPS/HTTP communication between Web requests and the JDBC Server Web UI server **NOTE** The system verifies the port configuration. If the port is invalid, the value of the port plus 1 is used till the calculated value is valid. (A maximum number of 16 attempts are allowed. The number of attempts is specified by **spark.port.maxRetries**.) ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes

Parameter	Default Open Source Port	Default Custom Port	Port Description
spark.history.ui.port	18080	22500	JobHistory Web UI port This port is used for: HTTPS/HTTP communication between Web requests and Spark2.1.0 History Server **NOTE** The system verifies the port configuration. If the port is invalid, the value of the port plus 1 is used till the calculated value is valid. (A maximum number of 16 attempts are allowed. The number of attempts is specified by **spark.port.maxRetries**.) • Is the port enabled by default during the installation: Yes • Is the port enabled after security hardening: Yes

Common Storm Ports

The protocol type of all ports in the table is TCP.

Parameter	Default Open Source Port	Default Custom Port	Port Description
nimbus.thrift.port	6627	29200	Port for Nimbus to provide thrift services
supervisor.slots.ports	6700,6701,6702,6703	29200-29499	Port for receiving service requests that are forwarded from other servers
logviewer.https.port	29248	29248	Port for LogViewer to provide HTTPS services
ui.https.port	29243	29243	Port for Storm UI to provide HTTPS services (ui.https.port)

Common Yarn Ports

The protocol type of all ports in the table is TCP.

Parameter	Default Open Source Port	Default Custom Port	Port Description
yarn.resourcemanager.webapp.port	8088	26000	Web HTTP port of the ResourceManager service
yarn.resourcemanager.webapp.https.port	8090	26001	Web HTTPS port of the ResourceManager service This port is used to access the Resource Manager web applications in security mode. **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
yarn.nodemanager.webapp.port	8042	26006	NodeManager Web HTTP port
yarn.nodemanager.webapp.https.port	8044	26010	NodeManager Web HTTPS port This port is used for: Accessing the NodeManager web application in security mode **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes

Common ZooKeeper Ports

The protocol type of all ports in the table is TCP.

Parameter	Default Open Source Port	Default Custom Port	Port Description
clientPort	2181	24002	ZooKeeper client port This port is used for: Connection between the ZooKeeper client and server. **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes

Common Kerberos Ports

The protocol type of all ports in the table is TCP and UDP.

Parameter	Default Port	Port Description
kdc_ports	21732	Kerberos server port This port is used for performing Kerberos authentication for components. This parameter may be used during the configuration of mutual trust between clusters. **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes

Common OpenTSDB Ports

The protocol type of the port in the table is TCP.

Parameter	Default Port	Port Description
tsd.network.port	4242	Web UI port of OpenTSDB This port is used for: HTTPS/HTTP communication between web requests and the OpenTSDB UI server

Common Tez Ports

The protocol type of the port in the table is TCP.

Parameter	Default Port	Port Description
tez.ui.port	28888	Web UI port of Tez

Common KafkaManager Ports

The protocol type of the port in the table is TCP.

Parameter	Default Port	Port Description
kafka_manager_port	9099	Web UI port of KafkaManager

Common Presto Ports

The protocol type of the port in the table is TCP.

Parameter	Default Port	Port Description
http-server.http.port	7520	HTTP port for Presto coordinator to provide services to external systems
http-server.https.port	7521	HTTPS port for Presto coordinator to provide services to external systems
http-server.http.port	7530	HTTP port for Presto worker to provide services to external systems

Parameter	Default Port	Port Description
http-server.https.port	7531	HTTPS port for Presto worker to provide services to external systems

Common Flink Ports

The protocol type of the port in the table is TCP.

Parameter	Default Port	Port Description
jobmanager.web.port	32261-32325	Web UI port of Flink This port is used for: HTTP/HTTPS communication between the client web requests and Flink server

Common ClickHouse Ports

The protocol type of the port in the table is TCP and HTTP.

Parameter	Default Open Source Port	Default Custom Port	Port Description
interserver_http_port	9009	9009	HTTP port for the communication between ClickHouse servers.
interserver_https_port	9010	9010	HTTPS port for the communication between ClickHouse servers.
http_port	8123	8123	Port for connecting to the ClickHouse server through HTTP.
https_port	8443	8443	Port for connecting to the ClickHouse server through HTTPS.
tcp_port	9000	9000	Port for connecting the client to the ClickHouse server through TCP.
tcp_port_secure	9440	9440	Port for connecting the client to the ClickHouse server through TCP SSL.

Parameter	Default Open Source Port	Default Custom Port	Port Description
lb_tcp_port	21424	21424	TCP port listened by ClickHouseBalancer
lb_http_port	21425	21425	HTTP port listened by ClickHouseBalancer
lb_https_port	21426	21426	HTTPS port listened by ClickHouseBalancer
lb_tcp_secure_port	21428	21428	TCP SSL port listened by ClickHouseBalancer

Common Impala Ports

The protocol type of the port in the table is TCP.

Parameter	Default Port	Port Description
--beeswax_port	21000	Port for impala-shell communication
--hs2_port	21050	Port for Impala application communication
--hs2_http_port	28000	Port used by Impala to provide the HiveServer2 protocol for external systems

8.3 Access Through Direct Connect

MRS allows you to access MRS clusters using Direct Connect. Direct Connect is a high-speed, low-latency, stable, and secure dedicated network connection that connects your local data center to an online cloud VPC. It extends online cloud services and existing IT facilities to build a flexible, scalable hybrid cloud computing environment.

Prerequisites

Direct Connect is available, and the connection between the local data center and the online VPC has been established.

Accessing an MRS Cluster Using Direct Connect

Step 1 Log in to the MRS console.

Step 2 Click the name of the cluster to enter its details page.

Step 3 On the **Dashboard** tab page of the cluster details page, click **Access Manager** next to **MRS Manager**.

Step 4 Set **Access Mode** to **Direct Connect** and select **I confirm that the network between the local PC and the floating IP address is connected and that MRS Manager is accessible using the Direct Connect connection**.

The floating IP address is automatically allocated by MRS to access MRS Manager. Before using Direct Connect to access MRS Manager, ensure that the connection between the local data center and the online VPC has been established.

Step 5 Click **OK**. The MRS Manager login page is displayed. Enter the username **admin** and the password set during cluster creation.

----End

Switching the MRS Manager Access Mode

To facilitate user operations, the browser cache records the selected Manager access mode. To change the access mode, perform the following steps:

Step 1 Log in to the MRS console.

Step 2 Click the name of the cluster to enter its details page.

Step 3 On the **Dashboard** tab page of the cluster details page, click ⇌ next to **MRS Manager**.

Step 4 On the displayed page, set **Access Mode**.

- To change **EIP** to **Direct Connect**, ensure that the network for direct connections is available, set **Access Mode** to **Direct Connect**, and select **I confirm that the network between the local PC and the floating IP address is connected and that MRS Manager is accessible using the Direct Connect connection**. Click **OK**.
- To change **Direct Connect** to **EIP**, set **Access Mode** to **EIP** and configure the EIP by referring to **Accessing FusionInsight Manager Using EIP**. If a public IP address has been configured for the cluster, click **OK** to access MRS Manager using an EIP.

----End

8.4 EIP-based Access

You can bind an EIP to a cluster to access the web UIs of the open-source components managed in the MRS cluster. This method is simple and easy to use and is recommended for accessing the web UIs of the open-source components.

Binding an EIP to a Cluster and Adding a Security Group Rule

1. On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users. After the IAM users are synchronized, the **Components** tab is available.

2. Click **Access Manager** on the right of **MRS Manager**.
3. The page for accessing MRS Manager is displayed. Bind an EIP and add a security group rule. Perform the following operations only when you access the web UIs of the open-source components of the cluster for the first time.
   a. Select an available EIP from the EIP drop-down list to bind it. If there is no available EIP, click **Manage EIP** to create an EIP. If an EIP has been bound during cluster creation, skip this step.
   b. Select the security group to which the security group rule to be added belongs. The security group is configured when the group is created.
   c. Add a security group rule. By default, your public IP address used for accessing port 9022 is filled in the rule. If you want to view, modify, or delete a security group rule, click **Manage Security Group Rule**.

      NOTE

      - It is normal that the automatically generated public IP address is different from the local IP address and no action is required.
      - If port 9022 is a Knox port, you need to enable the permission of port 9022 to access Knox for accessing MRS components.

   d. Select the checkbox stating that **I confirm that xx.xx.xx.xx is a trusted public IP address and MRS Manager can be accessed using this IP address**.
   e. Click **OK**. The login page is displayed. Enter the username **admin** and the password set during cluster creation.
4. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **HDFS**. On the displayed page, click **NameNode(*Host name*, active)** to access the HDFS web UI. The HDFS NameNode is used as an example. For details about the web UIs of other components, see **Web UIs of Open Source Components**.

8.5 Access Using a Windows ECS

MRS allows you to access the web UIs of open-source components through a Windows ECS. This method is complex and is recommended for MRS clusters that do not support the EIP function.

Step 1 On the MRS management console, click **Clusters**.

Step 2 On the **Active Clusters** page, click the name of the specified cluster.

On the cluster details page, record the **AZ**, **VPC**, **Floating IP Address of OMS**, and **Security Group** of the cluster.

NOTE

To obtain the floating IP address of OMS, log in to the Master2 node remotely, and run the **ifconfig** command. In the command output, **eth0:wsom** indicates the floating IP address of OMS. Record the value of **inet**. If the floating IP address of OMS cannot be queried on the Master2 node, switch to the Master1 node to query and record the floating IP address. If there is only one Master node, query and record the cluster manager IP address of the Master node.

Step 3 On the ECS management console, create an ECS.

- The **AZ**, **VPC**, and **Security Group** of the ECS must be the same as those of the cluster to be accessed.
- Select a Windows public image. For example, select the standard image **Windows Server 2012 R2 Standard 64bit(40GB)**.
- For details about other configuration parameters, see **Elastic Cloud Server > User Guide > Getting Started > Creating and Logging In to a Windows ECS**.

NOTE

If the security group of the ECS is different from **Security Group** of the MRS cluster, you can modify the configuration using either of the following methods:

- Change the security group of the ECS to the security group of the MRS cluster. For details, see **Elastic Cloud Server** > **User Guide** > **Security Group** > **Changing a Security Group**.
- Add two security group rules to the security groups of the Master and Core nodes to enable the ECS to access the cluster. Set **Protocol** to **TCP** and **ports** of the two security group rules to **28443** and **20009**, respectively. For details, see **Virtual Private Cloud** > **User Guide** > **Security** > **Security Group** > **Adding a Security Group Rule**.

Step 4 On the VPC management console, apply for an EIP and bind it to the ECS.

For details, see **Virtual Private Cloud** > **User Guide** > **Elastic IP** > **Assigning an EIP and Binding It to an ECS**.

Step 5 Log in to the ECS.

The Windows system account, password, EIP, and security group rules are required for logging in to the ECS. For details, see **Elastic Cloud Server > User Guide > Instances > Logging In to a Windows ECS**.

Step 6 On the Windows remote desktop, use your browser to access Manager.

The Manager access address is in **https://***OMS floating IP address*:**28443/web** format. Enter the name and password of the MRS cluster user, for example, user **admin**.

NOTE

- To obtain the floating IP address of OMS, log in to the Master2 node remotely, and run the **ifconfig** command. In the command output, **eth0:wsom** indicates the floating IP address of OMS. Record the value of **inet**. If the floating IP address of OMS cannot be queried on the Master2 node, switch to the Master1 node to query and record the floating IP address. If there is only one Master node, query and record the cluster manager IP address of the Master node.
- If you access MRS Manager with other MRS cluster usernames, change the password upon your first access. The new password must meet the requirements of the current password complexity policies.
- By default, a user is locked after inputting an incorrect password five consecutive times. The user is automatically unlocked after 5 minutes.

Step 7 Visit the web UIs of the open-source components by referring to the addresses listed in **Web UIs of Open Source Components**.

----End

Related Tasks

Configuring the Mapping Between Cluster Node Names and IP Addresses

Step 1 Log in to MRS Manager, and choose **Host Management**.

Record the host names and management IP addresses of all nodes in the cluster.

Step 2 In the work environment, use Notepad to open the **hosts** file and add the mapping between node names and IP addresses to the file.

Fill in one row for each mapping relationship, as shown in the following figure.

```
192.168.4.127 node-core-Jh3ER
192.168.4.225 node-master2-PaWVE
192.168.4.19 node-core-mtZ81
192.168.4.33 node-master1-zbYN8
192.168.4.233 node-core-7KoGY
```

Save the modifications.

----End

8.6 Creating an SSH Channel for Connecting to an MRS Cluster and Configuring the Browser

Scenario

Users and an MRS cluster are in different networks. As a result, an SSH channel needs to be created to send users' requests for accessing websites to the MRS cluster and dynamically forward them to the target websites.

The MAC system does not support this function. For details about how to access MRS, see **EIP-based Access**.

Prerequisites

- You have prepared an SSH client for creating the SSH channel, for example, the Git open-source SSH client. You have downloaded and installed the client.
- You have created a cluster and prepared a key file in PEM format or obtained the password used during cluster creation.
- Users can access the Internet on the local PC.

Procedure

Step 1 Log in to the MRS management console and choose **Clusters** > **Active Clusters**.

Step 2 Click the specified MRS cluster name.

Record the security group of the cluster.

Step 3 Add an inbound rule to the security group of the Master node to allow data access to the IP address of the MRS cluster through port **22**.

For details, see **Virtual Private Cloud** > **User Guide** > **Security** > **Security Group** > **Adding a Security Group Rule**.

Step 4 Query the primary management node of the cluster. For details, see **Determining Active and Standby Management Nodes**.

Step 5 Bind an elastic IP address to the primary management node.

For details, see **Virtual Private Cloud** > **User Guide** > **Elastic IP** > **Assigning an EIP and Binding It to an ECS**.

Step 6 Start Git Bash locally and run the following command to log in to the active management node of the cluster: **ssh root@*Elastic IP address*** or **ssh -i *Path of the key file* root@*Elastic IP address***.

Step 7 Run the following command to view data forwarding configurations:

cat /etc/sysctl.conf | grep net.ipv4.ip_forward

- If **net.ipv4.ip_forward=1** is displayed, the forwarding function has been configured. Go to **Step 9**.
- If **net.ipv4.ip_forward=0** is displayed, the forwarding function has not been configured. Go to **Step 8**.
- If **net.ipv4.ip_forward** fails to be queried, this parameter has not been configured. Run the following command and then go to **Step 9**:

  echo "net.ipv4.ip_forward = 1" >> /etc/sysctl.conf

Step 8 Modify forwarding configurations on the node.

1. Run the following command to switch to user **root**:

   sudo su - root

2. Run the following commands to modify forwarding configurations:

   echo 1 > /proc/sys/net/ipv4/ip_forward

   sed -i "s/net.ipv4.ip_forward=0/net.ipv4.ip_forward = 1/g" /etc/sysctl.conf

   sysctl -w net.ipv4.ip_forward=1

3. Run the following command to modify the **sshd** configuration file:

   vi /etc/ssh/sshd_config

   Press **I** to enter the edit mode. Locate **AllowTcpForwarding** and **GatewayPorts** and delete comment tags. Modify them as follows. Save the changes and exit.

   ```
   AllowTcpForwarding yes
   GatewayPorts yes
   ```

4. Run the following command to restart the sshd service:

   service sshd restart

Step 9 Run the following command to view the floating IP address:

ifconfig

In the command output, **eth0:FI_HUE** indicates the floating IP address of Hue and **eth0:wsom** specifies the floating IP address of Manager. Record the value of **inet**.

Run the **exit** command to exit.

Step 10 Run the following command on the local PC to create an SSH channel supporting dynamic port forwarding:

ssh -i *Path of the key file* -v -ND *Local port* root@*Elastic IP address* or ***ssh -v -ND Local port root@Elastic IP address***. After running the command, enter the password you set when you create the cluster.

In the command, set **Local port** to the user's local port that is not occupied. Port **8157** is recommended.

After the SSH channel is created, add **-D** to the command and run the command to start the dynamic port forwarding function. By default, the dynamic port forwarding function enables a SOCKS proxy process and monitors the user's local port. Port data will be forwarded to the primary management node using the SSH channel.

Step 11 Run the following command to configure the browser proxy.

1. Go to the Google Chrome client installation directory on the local PC.
2. Press **Shift** and right-click the blank area, choose **Open Command Window Here** and enter the following command:

   chrome --proxy-server="socks5://localhost:8157" --host-resolver-rules="MAP * 0.0.0.0 , EXCLUDE localhost" --user-data-dir=c:/tmppath --proxy-bypass-list="*google*com,*gstatic.com,*gvt*.com,*:80"

   NOTE

   - In the preceding command, **8157** is the local proxy port configured in **Step 10**.
   - If the local OS is Windows 10, start the Windows OS, click **Start** and enter **cmd**. In the displayed CLI, run the command in **Step 11.2**. If this method fails, click **Start**, enter the command in the search box, and run the command in **Step 11.2**.

Step 12 In the address box of the browser, enter the address for accessing Manager.

Address format: **https://***Floating IP address of FusionInsight Manager***:28443/web**

The username and password of the MRS cluster need to be entered for accessing clusters with Kerberos authentication enabled, for example, user **admin**. They are not required for accessing clusters with Kerberos authentication disabled.

When accessing Manager for the first time, you must add the address to the trusted site list.

Step 13 Prepare the website access address.

1. Obtain the website address format and the role instance according to **Web UIs**.
2. Click **Services**.
3. Click the specified service name, for example, HDFS.
4. Click **Instance** and view **Service IP Address** of **NameNode(Active)**.

Step 14 In the address bar of the browser, enter the website address to access it.

Step 15 When logging out of the website, terminate and close the SSH tunnel.

----End

9 Accessing FusionInsight Manager

Scenario

In MRS 3.*x* or later, FusionInsight Manager is used to monitor, configure, and manage clusters. After a cluster is installed, you can use an account to log in to FusionInsight Manager.

Currently, you can access FusionInsight Manager using the following methods:

- **Accessing FusionInsight Manager Using EIP**
- **Accessing FusionInsight Manager Using Direct Connect**
- **Accessing FusionInsight Manager from an ECS**

You can switch the access methods between **EIP** and **Direct Connect** on the MRS console by performing the following steps:

Log in to the MRS management console and click the desired cluster. On the displayed page, click ⇌ next to **MRS Manager** on the **Dashboard** tab, and switch the access method.

NOTE

If you cannot log in to the WebUI of the component, access FusionInsight Manager by referring to **Accessing FusionInsight Manager from an ECS**.

FusionInsight Manager cannot be accessed when the cluster is in any of the following states:

Starting, Stopping, Stopped, Deleting, Deleted, and Frozen.

Accessing FusionInsight Manager Using EIP

If the EIP address function is enabled for the cluster, perform the following steps:

Step 1 Log in to the MRS management console.

Step 2 In the navigation pane, choose **Clusters** > **Active Clusters**. Click the target cluster name to access the cluster details page.

Step 3 Click **Manager** next to **MRS Manager**. In the displayed dialog box, configure the EIP information.

1. If no EIP is bound during MRS cluster creation, select an available EIP from the drop-down list on the right of **IEP**. If you have bound an EIP when you create a cluster, go to **Step 3.2**.

   NOTE

   - If no EIPs are available, click **Manage EIP** to create one. Then, select the EIP from the drop-down list.
   - To unbind or release an EIP after using it, log in to the **EIPs** page, locate the row containing the target EIP, and click **Unbind** or choose **More** > **Release** in the **Operation** column.
   - If an EIP has been created but cannot be found during binding, the EIP may have been bound to another cluster. In this case, unbind the EIP on the **EIPs** page and then bind it to the current cluster.

2. In **Security Group**, select the security group to which the current cluster belongs. The security group is configured during cluster creation or is automatically created by the cluster.

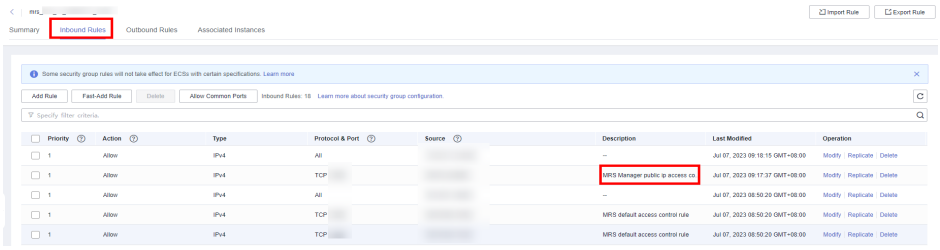
   NOTE

   - When creating a custom cluster, you can configure a security group created in advance or retain the default value **Auto create**. When you quickly create a cluster, the security group is automatically created by the cluster.
   - You can view the security group name in **Security Group** on the **Dashboard** tab page of the cluster.

3. Add a security group rule. By default, the filled-in rule is used to access the EIP. To enable multiple IP address segments to access Manager, see steps **Step 6** to **Step 9**. If you want to view, modify, or delete a security group rule, click **Manage Security Group Rule**.

   NOTE

   "MRS Manager public ip access control rule" is added to the **Description** column of the the security group rule you added. To view this description, choose **Manage Security Group Rule**, click **Security Group**, and click the **Inbound Rules** tab.

4. Select the information to be confirmed and click **OK**.

   NOTE

   Click ⇌ on the right of **Access Manager** to change the FusionInsight Manager access mode. For details about how to access FusionInsight Manager by using **Direct Connect**, see **Accessing FusionInsight Manager by Using Direct Connect**.

Step 4 Click **OK**. The Manager login page is displayed.

NOTE

Before accessing Manager, ensure that the EIP can be pinged. If the ping operation fails, contact O&M support.

Step 5 Enter the default username **admin** and the password set during cluster creation, and click **Log In**. The Manager page is displayed.

Step 6 On the MRS management console, choose **Clusters** > **Active Clusters**. Click the target cluster name to access the cluster details page.

NOTE

To grant other users the permission to access Manager, perform **Step 6** to **Step 9** to add the users' public IP addresses to the trusted IP address range.

Step 7 Click **Add Security Group Rule** next to **EIP**.

Step 8 On the **Add Security Group Rule** page, add the IP address segment for users to access the public network and select **I confirm that *public network IP*|*port* is a trusted public IP address. I understand that using 0.0.0.0/0. poses security risks**.

By default, the IP address used for accessing the public network is filled. You can change the IP address segment as required. To enable multiple IP address segments, repeat steps **Step 6** to **Step 9**. If you want to view, modify, or delete a security group rule, click **Manage Security Group Rule**.

Step 9 Click **OK**.

----End

Accessing FusionInsight Manager by Using Direct Connect

You need to ensure that Direct Connect is available, and the connection between the local data center and the online VPC has been established.

Step 1 Log in to the MRS console.

Step 2 Click the name of the cluster to enter its details page.

Step 3 On the **Dashboard** tab page of the cluster details page, click **Access Manager** next to **MRS Manager**.

Step 4 Set **Access Mode** to **Direct Connect** and select **I confirm that the network between the local PC and the floating IP address is connected and that MRS Manager is accessible using the Direct Connect connection**.

The floating IP address is automatically allocated by MRS to access MRS Manager. Before using Direct Connect to access MRS Manager, ensure that the connection between the local data center and the online VPC has been established.

Step 5 Click **OK**. The MRS Manager login page is displayed. Enter the username **admin** and the password set during cluster creation.

----End

Accessing FusionInsight Manager from an ECS

Step 1 On the MRS management console, click **Clusters**.

Step 2 On the **Active Clusters** page, click the name of the specified cluster.

Record the **AZ**, **VPC**, **MRS ManagerSecurity Group** of the cluster.

Step 3 On the homepage of the management console, choose **Service List** > **Elastic Cloud Server** to switch to the ECS management console and create an ECS.

- The **AZ**, **VPC**, and **Security Group** of the ECS must be the same as those of the cluster to be accessed.
- Select a Windows public image. For example, a standard image **Windows Server 2012 R2 Standard 64bit(40GB)**.
- For details about other configuration parameters, see **Elastic Cloud Server > User Guide > Getting Started > Creating and Logging In to a Windows ECS**.

NOTE

If the security group of the ECS is different from **Default Security Group** of the Master node, you can modify the configuration using either of the following methods:

- Change the security group of the ECS to the default security group of the Master node. For details, see **Elastic Cloud Server** > **User Guide** > **Security Group** > **Changing a Security Group**.
- Add two security group rules to the security groups of the Master and Core nodes to enable the ECS to access the cluster. Set **Protocol** to **TCP**, **Ports** of the two security group rules to **28443** and **20009**, respectively. For details, see **Virtual Private Cloud > User Guide > Security > Security Group > Adding a Security Group Rule**.

If "Failed to add security group rules." is displayed, check whether the security group quota is sufficient. If more quotas are needed, increase the quotas or delete security group rules that are no longer used.

Step 4 On the VPC management console, apply for an EIP and bind it to the ECS.

For details, see **Virtual Private Cloud** > **User Guide** > **Elastic IP** > **Assigning an EIP and Binding It to an ECS**.

Step 5 Log in to the ECS.

The Windows system account, password, EIP, and security group rules are required for logging in to the ECS. For details, see **Elastic Cloud Server > User Guide > Instances > Logging In to a Windows ECS**.

Step 6 On the Windows remote desktop, use your browser to access Manager.

The address for accessing Manager is the address of the **MRS Manager** page. Enter the name and password of the cluster user, for example, user **admin**.

NOTE

- If you access Manager with other cluster usernames, change the password upon your first access. The new password must meet the requirements of the current password complexity policies. For details, contact the administrator.
- By default, a user is locked after inputting an incorrect password five consecutive times. The user is automatically unlocked after 5 minutes.

Step 7 Log out of FusionInsight Manager. To log out of Manager, move the cursor to  in the upper right corner and click **Log Out**.

----End

10 FusionInsight Manager Operation Guide

10.1 Getting Started

10.1.1 FusionInsight Manager Introduction

Overview

MRS allows you to manage and analyze massive amounts of structured and unstructured data for rapid data mining. Open source components have complex structures and therefore they are difficult to install, configure, and manage. FusionInsight Manager is a unified enterprise-level cluster management platform that provides:

- **Cluster monitoring**: enables you to quickly learn the running status of hosts and services.
- **Graphical metric monitoring and customization**: enable you to obtain key system information in a timely manner.
- **Service property configuration**: allows you to configure service properties based on the performance requirements of your services.
- **Cluster, service, and role instance operations**: allow you to start or stop services and clusters with just a few clicks.
- **Rights management and audit**: allow you to configure the access control and manage operation logs.

Introduction to the FusionInsight Manager GUI

FusionInsight Manager provides a unified cluster management platform, facilitating rapid and easy O&M for clusters.

The upper part of the page is the operation bar, the middle part is the display area, and the bottom part is the taskbar.

Table 10-1 describes the functions of each portal on the operation bar.

Table 10-1 Functions of each portal on the operation bar

Portal	Function Description
Homepage	Provides key alarms, cluster metrics, host monitoring metrics, and cluster monitoring metrics. For details, see **Home Page**.
Cluster	Provides guidance on how to monitor, operate, and configure services in a cluster, helping you manage services in a unified manner. For details, see **Cluster**.
Hosts	Provides guidance on how to monitor and operate hosts, helping you manage hosts in a unified manner. For details, see **Hosts**.
O&M	Provides guidance on how to query and handle alarms, helping you identify and rectify product faults and potential risks in a timely manner to ensure smooth system running. For details, see **O&M**.
Audit	Allows you to query and export audit logs, and view all user activities and operations. For details, see **Audit**.
Tenant Resources	Provides a unified tenant management platform. For details, see **Tenant Resources**.
System	Provides system management settings of FusionInsight Manager, such as user permission settings. For details, see **System Configuration**.

10.1.2 Querying the FusionInsight Manager Version

By viewing the FusionInsight Manager version, you can prepare for system upgrade and routine maintenance.

- Using the GUI:

  Log in to FusionInsight Manager. On the home page, click  in the upper right corner and choose **About** from the drop-down list. In the dialog box that is displayed, view the FusionInsight Manager version.

- Using the CLI

  a. Log in to the FusionInsight Manager active management node as user **root**.

  b. Run the following commands to check the version and platform information of FusionInsight Manager:

  su - omm

  cd ${BIGDATA_HOME}/om-server/om/sbin/pack

  ./queryManager.sh

  The following information is displayed:

  ```
  Version         Package                          Cputype
  ***             FusionInsight_Manager_***        x86_64
  ```

NOTE

*** indicates the version number. Replace it with the actual version number.

10.1.3 Logging In to FusionInsight Manager

Scenario

Log in to FusionInsight Manager using an account.

Procedure

Step 1 Obtain the URL for logging in to FusionInsight Manager.

Step 2 On login page, enter the username and password.

Step 3 Change the password upon your first login.

The password must meet the following complexity requirements:

- Contains 8 to 64 characters.
- Contains at least four types of the following: uppercase letters, lowercase letters, numbers, spaces, and special characters (`~!@#$%^&*()-_=+|[{}];',<.>/\?).
- Cannot be the same as the username or the username spelled backwards.
- Cannot be the same as the current password.

Step 4 Move the cursor over  in the upper right corner of home page, and choose **Logout** from the drop-down list. In the dialog box that is displayed, click **OK** to log out of the current user.

----End

10.1.4 Logging In to the Management Node

Scenario

Some O&M operation scripts and commands need to be run or can be run only on the active management node. You can identify and log in to the active or standby management node based on the following operations.

Checking and Logging In to the Active and Standby Management Nodes

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **OMS**.

In the **Basic Information** area, **Current Active** indicates the host name of the active management node, and **Current Standby** indicates the host name of the standby management node.

Click a host name to go to the host details page. On the host details page, record the IP address of the host.

Step 3 Log in to the active or standby management node as user **root**.

----End

Identifying the Active and Standby Management Nodes by Running Scripts and Logging In to Them

Step 1 Log in to any node where FusionInsight Manager is installed as user **root**.

Step 2 Run the following command to identify the active and standby management nodes:

su - omm

sh ${BIGDATA_HOME}/om-server/om/sbin/status-oms.sh

In the command output, the node whose **HAActive** is **active** is the active management node (Master1), and the node whose **HAActive** is **standby** is the standby node (Master2).

```
HAMode
double
NodeName            HostName        HAVersion         StartTime             HAActive
HAAllResOK          HARunPhase
192-168-0-30        Master1         V100R001C01       2021-09-01 07:12:05   active
normal              Actived
192-168-0-24        Master2         V100R001C01       2021-09-01 07:14:02   standby
normal              Deactived
```

Step 3 Run the following command to obtain the IP addresses of the active and standby management nodes:

cat /etc/hosts

Example IP addresses of the active and standby management nodes:

```
127.0.0.1       localhost
192.168.0.30    Master1
192.168.0.24    Master2
```

Step 4 Log in to the active or standby management node as user **root**.

----End

10.2 Home Page

10.2.1 Overview

After you log in to FusionInsight Manager, the **Homepage** is displayed by default. You can view key information in the **Alarms**, **System**, and **Cluster** modules on the homepage.

- On the upper right corner of the homepage, you can view the number of alarms of different severities, number of running tasks, current user, and help information.
  - Click  to view the task name, status, progress, start time, and end time of the last 100 operation tasks in **Task Management Center**.

NOTE

For a start, stop, restart, or rolling restart task, you can abort it by clicking the task name in the task list, clicking **Abort**, and then entering the system administrator password in the dialog box that is displayed. An aborted task is no longer executed.

- Click  to obtain help information.

  Table 10-2 Help information

Item	Description
About	Provides the FusionInsight Manager version information.

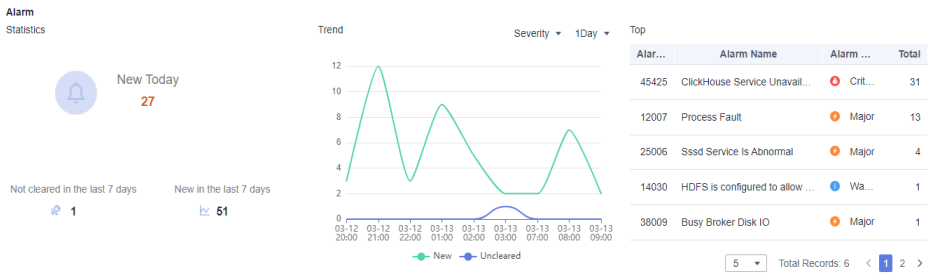
- Icons of services contained in the current cluster are displayed in ⇉ on the left of the home page. You can click ⇉ to view the service names and statuses.
- The taskbar at the bottom of the home page displays the language options of FusionInsight Manager and the current cluster time and time zone information. You can switch the system language as needed.

Key Alarm Information

The **Alarm** module displays key alarm information about the current cluster.

- **Statistics**: collects statistics on the number of new alarms on the current day, number of uncleared alarms in the last seven days, and number of new alarms in the last seven days.
- **Trend**: displays the change trend of new and uncleared alarms over time. You can filter the alarm severity and time to display.
- **Top**: displays the top 10 uncleared alarms ranked by occurrences.

Figure 10-1 Key alarm information



Key Cluster Information and Operations

The key information about the cluster is displayed in the upper right corner of the home page. The information is as follows:

- **Cluster**: name of the current cluster
- **Host**: number of hosts in the current cluster.

- **Yarn Running Tasks**: number of Yarn tasks running in the current cluster. This parameter is available when the cluster contains the Yarn service.
- **HDFS File**: number of HDFS files in the current cluster. This parameter is available when the cluster contains the HDFS service.
- **HDFS Disk Space**: used HDFS disk space and total HDFS disk space of the current cluster. The value is in the format of *Used HDFS disk space*/*Total HDFS disk space*. This parameter is available when the cluster contains the HDFS service.

In this area, you can also start, stop, perform rolling restart, and synchronize configurations of the cluster, as shown in **Table 10-3**.

Figure 10-2 Key cluster information

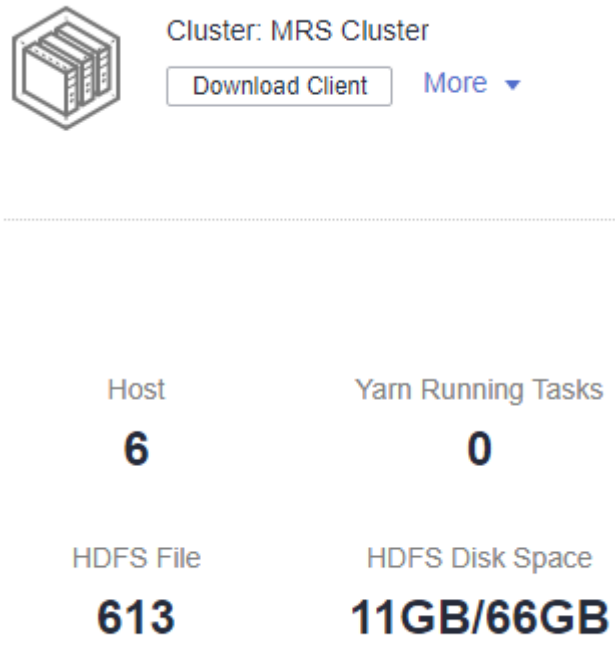


Table 10-3 Maintenance and management operations

Operation	Description
Downloading Client	Downloads the default client. For details, see **Downloading the Client**.
More > **Start**	Starts all services in the cluster.
More > **Stop**	Stops all services in the cluster.
More > **Restart**	Restarts all services in the cluster.
More > **Rolling-restart Service**	Restarts all services in the cluster at a time without interrupting workloads. For details about how to perform a rolling restart, see **Performing a Rolling Restart of a Cluster**.

Operation	Description
More > **Synchronize Configurations**	Enables new configuration parameters for all services in the cluster.
More > **Restart Configuration-Expired Instances**	Restarts expired instances for all services in the cluster. For details, see **Managing Expired Configurations**.
More > **Health Check**	Performs a health check on the OMS nodes, all services, and the rest nodes in the cluster. There are three types of check items: running status, related alarms, and custom monitoring metrics. The health check results are not always the same as the values of **Running Status** displayed on the GUI. To export the result of the health check, click **Export Report** in the upper left corner. If any problem is detected, click **Help**.
More > **Export Installation Template**	Batch exports all installation configurations of the cluster, such as the cluster authentication mode, node information, and service configuration. You can use this function when you need to reinstall the cluster in the same environment.
More > **Export Configurations**	Batch exports configurations of all services in the cluster.
More > **Enter/Exit Maintenance Mode**	Enters or exits the cluster maintenance mode.
More > **O&M View**	Allows you to view services or hosts that are in the maintenance mode.

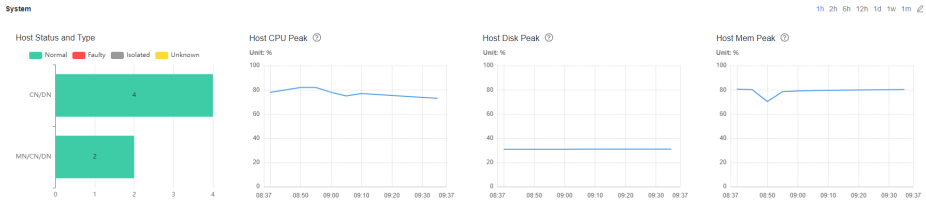
Key System Metrics

The **System** area on the homepage displays key metrics of the system.

- **Host Status and Type**: displays the number of hosts in different states and types.
- **Peak Host CPU Usage**: displays the peak CPU usage of the host over time.
- **Peak Host Disk Usage**: displays the peak disk usage of the host over time.
- **Peak Host Memory Usage**: displays the peak memory usage of the host over time.

You can select a time range for monitoring data in the upper right corner of the **System** area or click to customize a time range.

Figure 10-3 Key system metrics

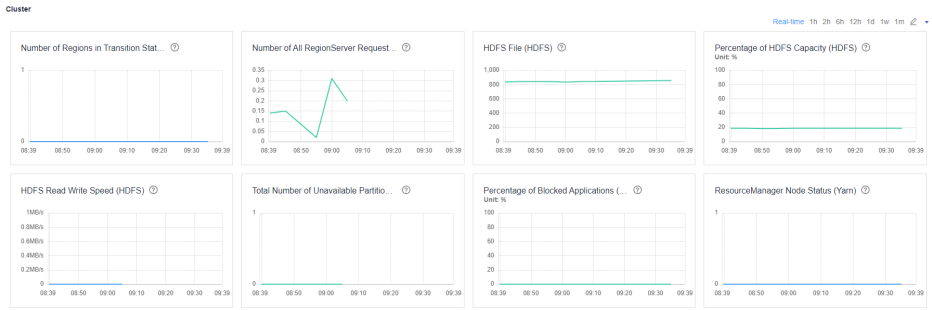


Key Cluster Metrics

The **Cluster** area on the homepage displays key metrics of the cluster. You can customize monitoring reports to display in this area. For details about how to manage monitoring metrics, see **Managing Monitoring Metric Reports**.

You can view the data source of a monitoring chart in the lower left corner of the chart. You can zoom in on a monitoring report to view chart values more clearly or close the monitoring report.

Figure 10-4 Key cluster metrics



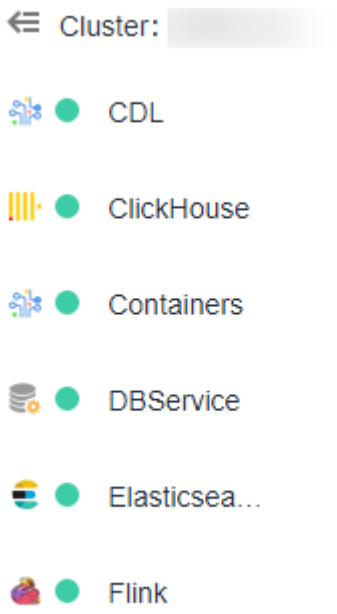
Service Status Preview Area

On the left of the homepage, you can view the status and alarms of each service installed in the current cluster.

The icon on the left of each service name indicates that the service is running properly; the icon indicates that the current service fails to start; and the icon indicates that the current service is not started.

The icon displayed on the right of the service name indicates that the service configuration has expired.

Figure 10-5 Service status preview area



10.2.2 Managing Monitoring Metric Reports

Scenario

On FusionInsight Manager, you can customize the cluster monitoring items to be displayed in the **Cluster** area on the home page and export monitoring data.

NOTE

The interval on the horizontal axis of the chart varies depending on the time period you specify. Data monitoring rules are as follows:

- **0 to 21 hours and 20 minutes**: The interval is 5 minutes. The cluster must have been installed for at least 10 minutes, and monitoring data of a maximum of 90 days is saved.
- **21 hours and 20 minutes to 128 hours**: The interval is 30 minutes. The cluster must have been installed for at least 30 minutes, and monitoring data of a maximum of 90 days is saved.
- **128 to 256 hours**: The interval is 1 hour. The cluster must have been installed for at least 1 hour, and monitoring data of a maximum of 90 days is saved.
- **256 hours to 256 days**: The interval is 1 day. The cluster must have been installed for at least 1 day, and monitoring data of a maximum of 90 days is saved.
- If the disk usage of the partition where GaussDB resides exceeds 80%, real-time monitoring data and monitoring data whose interval is 5 minutes will be deleted.
- **Storage resources (HDFS) in Tenant Resources (0 to 300 hours)**: The interval is 1 hour. The cluster must have been installed for at least 1 hour, and monitoring data of a maximum of 3 months is saved.

Customizing a Monitoring Metric Report

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Homepage**.

Step 3 In the upper right corner of the **Cluster** area, click and choose **Customize** from the displayed menu.

NOTE

Monitoring data of the past 1 hour is displayed at an interval of 5 minutes. After you enter the **Real-time Monitoring** page, you can view that real-time monitoring data is displayed on the right of the monitoring chart at an interval of 5 minutes.

Step 4 In the left pane of the **Customize Statistics** dialog box, select a resource to monitor.

Step 5 Select one or multiple monitoring metrics in the right pane.

Step 6 Click **OK**.

----End

Exporting All Monitoring Data

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Homepage**.

Step 3 In the upper right corner of the **Cluster** area, select a time range to obtain monitoring data, for example, **1w**.

Real-time data is displayed by default, which cannot be exported. You can click to customize a time range.

Step 4 In the upper right corner of the **Cluster** area, click and choose **Export** from the displayed menu.

----End

Exporting Monitoring Data of a Specified Monitoring Item

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Homepage**.

Step 3 In the upper right corner of any monitoring report pane in the **Cluster** area, click .

Step 4 Select a time range to obtain monitoring data, for example, **1w**.

Real-time data is displayed by default, which cannot be exported. You can click to customize a time range.

Step 5 Click **Export**.

----End

10.3 Cluster

10.3.1 Cluster Management

10.3.1.1 Performing a Rolling Restart of a Cluster

Scenario

A rolling restart is batch restarting all services in a cluster after they are modified or upgraded without interrupting workloads.

You can perform a rolling restart of a cluster as needed.

NOTE

- Certain services in a cluster do not support rolling restart. These services are restarted in normal mode during the rolling restart of the cluster. As a result, workloads may be interrupted. So, you need to determine whether to perform this operation as prompted.
- Configurations that must take effect immediately, for example, server port configurations, should be restarted in normal mode.

Impact on the System

A rolling restart takes a longer time and may affect service throughput and performance.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 In the upper right corner of **Homepage**, click **More** and select **Rolling-restart Service**.

Step 3 In the dialog box that is displayed, enter the password of the current login user and click **OK**.

Step 4 Configure the parameters based on site requirements.

Table 10-4 Rolling restart parameters

Parameter	Description
Restart only instances with expired configurations in the cluster	Whether to restart only the modified instances in a cluster
Enable rack strategy	Whether to enable the concurrent rack rolling restart strategy. This parameter takes effect only for roles that meet the rack rolling restart strategy. (The roles support rack awareness, and instances of the roles belong to two or more racks.) **NOTE** This parameter is configurable only when a rolling restart is performed on HDFS or Yarn.

Parameter	Description
Data Nodes to Be Batch Restarted	Number of instances that are restarted in each batch when the batch rolling restart strategy is used. The default value is **1**. **NOTE** • This parameter is valid only when the batch rolling restart strategy is used and the instance type is DataNode. • This parameter is invalid when the rack strategy is enabled. In this case, the cluster uses the maximum number of instances (20 by default) configured in the rack strategy as the maximum number of instances that are concurrently restarted in a rack. • This parameter is configurable only when a rolling restart is performed on HDFS, HBase, Yarn, Kafka, or Flume. • This parameter for the RegionServer of HBase cannot be manually configured. Instead, it is automatically adjusted based on the number of RegionServer nodes. Specifically, if the number of RegionServer nodes is less than 30, the parameter value is **1**. If the number is greater than or equal to 30 and less than 300, the parameter value is **2**. If the number is greater than or equal to 300, the parameter value is 1% of the number (rounded-down).
Batch Interval	Interval between two batches of instances to be roll-restarted. The default value is **0**.
Decommissioning Timeout Interval	Decommissioning interval for role instances during a rolling restart. The default value is **1800s**. Some roles (such as HiveServer and JDBCServer) stop providing services before the rolling restart. Stopped instances cannot be connected to new clients. Existing connections will be completed after a period of time. An appropriate timeout interval can ensure service continuity. **NOTE** This parameter is configurable only when Hive or Spark is roll-restarted.
Batch Fault Tolerance Threshold	Tolerance times when the rolling restart of instances fails to be batch executed. The default value is **0**, which indicates that the rolling restart task ends after any batch of instances fails to restart.

NOTE

Advanced parameters, such as **Data Nodes to Be Batch Restarted**, **Batch Interval**, and **Batch Fault Tolerance Threshold**, should be properly configured based on site requirements. Otherwise, services may be interrupted or cluster performance may be severely affected.

Example:

- If **Data Nodes to Be Batch Restarted** is set to an unnecessarily large value, a large number of instances are restarted concurrently. As a result, services are interrupted or cluster performance is severely affected due to too few working instances.
- If **Batch Fault Tolerance Threshold** is too large, services will be interrupted because a next batch of instances will be restarted after a batch of instances fails to restart.

Step 5 Click **OK**.

----End

10.3.1.2 Managing Expired Configurations

Scenario

If a new configuration needs to be delivered to all services in the cluster, or **Configuration Status** of multiple services changes to **Expired** or **Failed** after a configuration is modified, the configuration parameters of these services are not synchronized and do not take effect. In this case, synchronize the configurations and restart related service instances for the cluster so that the new parameters take effect for all services.

If the configuration of the services in the cluster has been synchronized but do not take effect, you need to restart the instances whose configuration has expired.

Impact on the System

- After synchronizing the cluster configuration, you need to restart the services whose configuration has expired. These services are unavailable during restart.
- The instances whose configuration has expired are unavailable during restart.

Procedure

Synchronize the configuration.

Step 1 Log in to FusionInsight Manager.

Step 2 In the upper right corner of **Homepage**, click **More** and select **Synchronize Configurations**.

Step 3 In the dialog box that is displayed, click **OK**.

----End

Restart configuration-expired instances.

Step 1 Choose **More** > **Restart Configuration-Expired Instances**.

Step 2 In the dialog box that is displayed, enter the password of the current login user and click **OK**.

Step 3 In the displayed dialog box, click **OK**.

You can click **View Instance** to open the list of all expired instances and confirm that the instances have been restarted.

----End

10.3.1.3 Downloading the Client

Scenario

Use the default client provided by MRS clusters to manage the cluster, run services, and perform secondary development. Before you use this client, you need to download its software package.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 In the upper right corner of the home page, click **Download Client**.

The **Download Cluster Client** dialog box is displayed.

Step 3 Select a client type for **Select Client Type**.

- **Complete Client**: the package contains scripts, compilation files, and configuration files.
- **Configuration Files Only**: the package contains only the client configuration files.

  This type is applicable to application development tasks. For example, after a complete client is downloaded and installed, the cluster administrator modifies the service configuration on FusionInsight Manager, and developers need to update the client configuration files.

NOTE

Set **Select Platform Type** to **x86_64** or **aarch64**. To run the client on x86 nodes, select **x86_64**; to tun the client on Arm nodes, select **aarch64**. By default, you should select a client that has the same architecture as your servers.

Step 4 Select the path for downloading the client file and set related parameters. Click **OK**.

- **Server**: Download the file to the active OMS node of the cluster.

  The generated file is stored in the **/tmp/FusionInsight-Client** directory on the active OMS node by default. You can also store the client file in other directories, and user **omm** has the read, write, and execute permissions on the directory. If the client file already exists in the path, the existing client file will be replaced.

  NOTE

  When a cluster has many services installed, the cluster client file becomes quite large. Additionally, decompressing this file during installation can consume significant disk space. It's recommended to download the client files to a different directory that has ample space, or to promptly remove unnecessary files from the client download directory after installation. Doing so helps avoid exhausting the **/tmp directory**'s disk space, which could interrupt the normal operation of the cluster nodes.

After the file is generated, copy the obtained package to another directory, for example, **/opt/Bigdata/hadoopclient**, as user **omm** or client installation user.

- **Browser**: Download the file to the local computer.
- **Remote node:** Download the file to a node other than the active OMS node. If you select this option, you need to set the following parameters:

Table 10-5 Parameters

Parameter	Description	Example Value
Save to Path	Path for storing client files. If there is already a client file in the path, it will be overwritten. For a remote node, write permission for the path is required.	/tmp/FusionInsight-Client-Remote/
Host IP Address	IP address of the remote node. **NOTE** The platform type of the remote node must be the same as that of the downloaded client. Otherwise, the client may fail to be installed.	x.x.x.x
Host Port	Host port of the remote node.	22
Username	Username for logging in to the remote node. For a remote node, write permission for the path is required.	xxx
Authentication Method	You can choose one of the following methods: – **Password**: Use the password for login. – **SSH private keys**: Use SSH private keys for login. – **None**: To use this method, passwordless login needs to be enabled for the node.	Password
Password	This parameter is mandatory when **Authentication Method** is set to **Password**. This parameter indicates the password used for login.	xxx

Parameter	Description	Example Value
SSH Private Keys	This parameter is mandatory when **Authentication Method** is set to **SSH private keys**. Click **Select File** and select a local file to upload.	-
Auto Deployment	Whether to enable auto deployment. This parameter is mandatory when **Select Client Type** is set to **Complete Client**. – If you set this parameter to **yes**, the client is automatically installed and deployed on the current node. – If you set this parameter to **no**, the client will not be automatically installed and deployed. You need to manually install the client after it is downloaded.	Yes
Deployment Path	This parameter is mandatory when **Auto Deployment** is set to **Yes**. If only the configuration file is downloaded, this parameter will not be displayed. The deployment path must be empty if it already exists on the remote node. Otherwise, it will be created automatically. The path also requires operate and write permissions.	/opt/testclient

Step 5 Install the downloaded client by referring to **Installing a Client**.

----End

10.3.1.4 Modifying Cluster Attributes

Scenario

View basic cluster attributes on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Cluster Properties**.

By default, you can view the cluster name, cluster description, product type, cluster ID, authentication mode, creation time, and installed components.

Step 3 Change the cluster name.

1. Click and enter a new name.

   Enter 2 to 199 characters. Only letters, digits, underscores (_), hyphens (-), and spaces are allowed, and the name cannot start with a space.
2. Click **OK** for the new cluster name to take effect.

Step 4 Modify the cluster description.

1. Click and enter a new description.

   Enter a maximum of 199 characters. Only letters, digits, commas (,), periods (.), underscores (_), spaces, and newline characters (\n) are allowed.
2. Click **OK** for the new description to take effect.

----End

10.3.1.5 Managing Cluster Configurations

Scenario

FusionInsight Manager allows you to view the changes of service configuration parameters in a cluster with one click, helping you quickly locate faults and improve configuration management efficiency.

You can quickly view all non-default values of each service in the cluster, non-uniform values between instances of the same role, historical records of cluster configuration modifications, and expired parameters in the cluster on the configuration page.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Configurations**.

Step 3 Select an operation page based on the scenario.

- To view all non-default values:
  a. Click **All Non-default Values**. The system displays the parameters whose values are different from the default values configured for each service, role, or instance in the current cluster.

     You can click next to a parameter value to quickly restore the value to the default one. You can click to view the historical modification records of the parameter.

If there are a large number of parameters to configure, you can filter the parameters in the filter box in the upper right corner of the page or enter keywords in the search box.

b. To change the values of the parameters, change the values according to the parameter description and click **Save**. In the dialog box that is displayed, click **OK**.

- To view all non-uniform values:
  a. Click **All Non-uniform Values**. The system displays parameters with different role, service, instance group, or instance configurations in the current cluster.

     You can click  next to a parameter value and view the differences in the dialog box that is displayed.

  b. To change the value of a parameter, click  to cancel the configuration difference or manually adjust the parameter value, click **OK**, and then click **Finish**. In the dialog box that is displayed, click **OK**.
- To check expired configurations:
  a. Click **Expired Configurations**. Expired configuration items in the current cluster are displayed.
  b. You can filter services using the service filter box in the upper part of the page to view expired configurations of different services. Alternatively, you can enter keywords in the search box.
  c. Expired configuration items do not take effect completely. Restart the services or instances whose configurations have expired in a timely manner.
- To view historical configuration records:
  a. Click **Historical Configurations**. The historical configuration change records of the current cluster are displayed. You can view details about parameter value changes, including the service to which the parameter belongs, parameter values before and after the modification, and parameter files.
  b. To restore a configuration change, click **Restore Configuration** in the **Operation** column of the target record. In the dialog box that is displayed, click **OK**.

NOTE

Some configuration items take effect only after the corresponding services are restarted. After the configurations are saved, restart the services or instances whose configurations have expired in a timely manner.

----End

10.3.1.6 Managing Static Service Pools

10.3.1.6.1 Static Service Resources

Overview

A cluster allocates static service resources to services. The services include FTP-Server, Flume, HBase, HDFS, Solr, Elasticsearch, IoTDB, Kafka, and Yarn. The total

volume of compute resources allocated to each service is fixed, and they are static. A tenant can exclusively use or share a service to obtain the resources required for running this service.

Static Service Pool

Static service pools are used to specify service resource configurations.

Static service pools centrally manage resources that can be used by each service.

- Limits the total number of resources that can be used by each service. Specifically, the total number of CPU, I/O, and memory resources can be configured on the nodes where services FTP-Server, Flume, HBase, HDFS, Solr, Elasticsearch, IoTDB, Kafka, and Yarn are deployed.
- Isolates the resources of services in a cluster from those of other services. In this way, the load of one service has very limited impact on other services.

Scheduling Mechanism

The time-based dynamic resource scheduling mechanism enables different volumes of static resources to be configured for services at different time, optimizing service running environments and improving the cluster efficiency.

In a complex cluster environment, multiple services share resources in the cluster, but the resource service period of each service may be different.

The following use a bank customer as an example:

- The HBase query service is heavy in the daytime.
- The query service is light, but the Hive analysis service is heavy at night.

If fixed resources are allocated to each service, the following problems may occur:

- The query service cannot obtain sufficient resources while the resources for the analysis service are idle in the daytime.
- The analysis service cannot obtain sufficient resources while the resources for the query service are idle at night.

As a result, the cluster resource utilization is low and the service capability is weak. Resolve the problem in the following ways:

- Sufficient resources need to be configured for HBase in the daytime.
- Sufficient resources need to be configured for Hive at night.

The time-based dynamic scheduling mechanism can efficiently utilize resources and run tasks.

10.3.1.6.2 Configuring Cluster Static Resources

Scenario

You can adjust resource base on FusionInsight Manager and customize resource configuration groups if you need to control service resources used on each node in a cluster or the available CPU or I/O quotas on each node at different time segments.

Impact on the System

- After a static service pool is configured, the configuration status of affected services is displayed as **Expired**. You need to restart the services. Services are unavailable during restart.
- After a static service pool is configured, the maximum number of resources used by each service and role instance cannot exceed the upper limit.

Procedure

Modify the Resource Adjustment Base

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Static Service Pool Configurations**.

Step 2 Click **Configuration** in the upper right corner. The page for configuring resource pools is displayed.

Step 3 Change the values of **CPU (%)** and **Memory (%)** in the **System Resource Adjustment Base** area.

Modifying the system resource adjustment base changes the maximum physical CPU and memory usage on nodes by services. If multiple services are deployed on the same node, the maximum physical resource usage of all services cannot exceed the adjusted CPU or memory usage.

Step 4 Click **Next**.

To modify parameters again, click **Previous**.

Modify the Default Resource Configuration Group

Step 5 Click **default**. In the **Configure weight** table, set **CPU LIMIT(%)**, **CPU SHARE(%)**, **I/O(%)**, and **Memory(%)** for each service.

NOTE

- The sum of **CPU LIMIT(%)** and **CPU SHARE(%)** used by all services can exceed 100%.
- The sum of **I/O(%)** used by all services can exceed 100% but cannot be 0.
- The sum of **Memory(%)** used by all services can be greater than, smaller than, or equal to 100%.
- **Memory(%)** cannot take effect dynamically and can only be modified in the default configuration group.
- **CPU LIMIT(%)** is used to configure the ratio of the number of CPU cores that can be used by a service to those can be allocated to related nodes.
- **CPU SHARE(%**) is used to configure the ratio of the time when a service uses a CPU core to the time when other services use the CPU core. That is, the ratio of time when multiple services compete for the same CPU core.

Step 6 Click **Generate detailed configurations based on weight configurations**. FusionInsight Manager generates the actual values of the parameters in the default weight configuration table based on the cluster hardware resources and allocation information.

Step 7 Click **OK**.

In the displayed dialog box, click **OK**.

Add a Customized Resource Configuration Group

Step 8 Determine whether to automatically adjust resource configurations at different time segments.

- If yes, go to **Step 9**.
- If no, use the default configurations, and no further action is required.

Step 9 Click **Configuration**, change the system resource adjustment base values, and click **Next**.

Step 10 Click **Add** to add a resource configuration group.

Step 11 In **Step 1: Scheduling Time**, click **Configuration**. The time policy configuration page is displayed.

Modify the following parameters based on service requirements and click **OK**.

- **Repeat**: If selected, the resource configuration group runs repeatedly based on the scheduling period. If not selected, set the date and time when the configuration of the group of resources can be applied.
- **Repeat Policy**: can be set to **Daily**, **Weekly**, and **Monthly**. This parameter is available only when **Repeat** is selected.
- **Between**: indicates the time period between the start time and end time when the resource configuration is applied. Set a unique time range. If the time range overlaps with that of an existing group of resource configuration, the time range cannot be saved.

NOTE

- The **default** group of resource configuration takes effect in all undefined time segments.
- The newly added resource group is a parameter set that takes effect dynamically in a specified time range.
- The newly added resource group can be deleted. A maximum of four resource configuration groups that take effect dynamically can be added.
- Select a repetition policy. If the end time is earlier than the start time, the end time of the next day is labeled by default. For example, if a validity period ranges from 22:00 to 06:00, the customized resource configuration takes effect from 22:00 on the current day to 06:00 on the next day.
- If the repeat policy types of multiple configuration groups are different, the time ranges can overlap. The policy types are listed as follows by priority from low to high: daily, weekly, and monthly. The following is an example. There are two resource configuration groups using the monthly and daily policies, respectively. Their application time ranges in a day overlap as follows: [04:00 to 07:00] and [06:00 to 08:00]. In this case, the configuration of the group that uses the monthly policy prevails.
- If the repeat policy types of multiple resource configuration groups are the same, the time ranges of different dates can overlap. For example, if there are two weekly scheduling groups, you can set the same time range on different day for them, such as to 04:00 to 07:00, on Monday and Wednesday, respectively.

Step 12 Modify the resource configuration of each service in **Step 2: Weight Configuration**.

Step 13 Click **Generate detailed configuration**. FusionInsight Manager generates the actual values of the parameters in the default weight configuration table based on the cluster hardware resources and allocation information.

Step 14 Click **OK**.

In the displayed dialog box, click **OK**.

----End

10.3.1.6.3 Viewing Cluster Static Resources

Scenario

The big data management platform can manage and isolate service resources that are not running on Yarn using static service resource pools. The system supports time-based automatic adjustment of static service resource pools. This enables the cluster to automatically adjust the parameter values at different periods to ensure more efficient resource utilization.

System administrators can view the monitoring indicators of resources used by each service in the static service pool on FusionInsight Manager. The monitoring indicators are as follows:

- CPU usage of services
- Total disk I/O read rate of services
- Total disk I/O write rate of services
- Total used memory of services

NOTE

After the multi-tenant function is enabled, the CPU, I/O, and memory usage of all HBase instances can be centrally managed.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Static Service Pool Configurations**.

Step 2 In the configuration group list, click a configuration group, for example, **default**.

Step 3 Check the system resource adjustment base values.

- **System Resource Adjustment Base** indicates the maximum volume of resources that can be used by each node in the cluster. If a node has only one service, the service exclusively occupies the available resources on the node. If a node has multiple services, all services share the available resources on the node.
- **CPU** indicates the maximum number of CPUs that can be used by services on a node.
- **Memory** indicates the maximum memory that can be used by services on a node.

Step 4 In **Chart**, view the metric data of the cluster service resource usage.

NOTE

- You can click **Add Service to Chart** to add static service resource data of specific services (up to 12 services) to the chart.
- For details about how to manage a chart, see **Managing Monitoring Metric Reports**.

----End

10.3.1.7 Managing Clients

10.3.1.7.1 Managing a Client

Scenario

FusionInsight Manager supports unified management of cluster client installation information. After a user downloads and installs a client, FusionInsight Manager automatically records information about the installed (registered) client to facilitate query and management. In addition, you can manually add or modify the information about clients that are not automatically registered, for example, clients installed in earlier versions.

Procedure

View client information.

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** and choose **Client Management** to view information about clients installed in the cluster.

You can view the IP address, installation path, component list, registration time, installation user, platform type, and version of the node where the client is located.

When the client is downloaded and installed in the cluster of the latest version, the client information is automatically registered.

Add client information.

Step 3 To manually add information about an installed client, click **Add** and manually add the IP address, installation path, user, platform type, and registration information of the client as prompted.

If a patch has been installed in the current cluster, you can select a patch version from **Patch Version**.

Step 4 Configure the client information and click **OK**.

Install MRS patches in batches.

Step 5 If a patch has been installed in the current cluster, select the clients on which the patch is to be installed on the **Client Management** page and choose **More** > **Batch install patches**. In the displayed dialog box, select "I accept the risk of possible service interruption during patch installation." Click **OK** to install the MRS patches on the selected client.

NOTE

During patch installation, clients cannot run properly and services on the clients may be interrupted.

Modify client information.

Step 6 Modify information about the manually registered client.

On the **Client Management** page, select the target client and click **Modify**. After modifying the information, click **OK**.

Delete client information.

Step 7 On the **Client Management** page, select the target client and click **Delete**. In the displayed dialog box, click **OK**.

To delete multiple clients, select target clients and click **More** > **Batch Delete**. In the displayed dialog box, click **OK**.

Export client information.

Step 8 On the **Client Management** page, click **Export All** to export information about all registered clients to the local PC.

NOTE

On the **Client Management** page, only components that have clients are displayed in the component list. Therefore, some components that do not have clients and have special components are not displayed.

The following components are not displayed:

LdapServer, KrbServer, DBService, Hue, Metadata, FTP-Server, MapReduce, and Flume

----End

10.3.1.7.2 Batch Upgrading Clients

Scenario

The client package downloaded from FusionInsight Manager contains the client batch upgrade tool. When multiple clients need to be upgraded after the cluster upgrade or scale-out, you can use this tool to upgrade the clients in batches with a few clicks. In addition, the tool provides the lightweight function of batch updating the **/etc/hosts** file on the nodes where the clients are located.

Procedure

Prepare for the client upgrade.

Step 1 Log in to FusionInsight Manager.

Step 2 In the upper right corner of **Homepage**, click **Download Client** to download the client and its files to a specified directory on the server.

For details, see **Downloading the Client**.

Decompress the downloaded client package and find the **batch_upgrade** directory, for example, **/tmp/FusionInsight-Client/FusionInsight_Cluster_1_Services_ClientConfig/batch_upgrade**.

Step 3 Choose **Cluster** > **Client Management**. On the **Client Management** page, click **Export All** to export all client information to the local PC.

Step 4 Decompress the exported client information and upload the **client-info.cfg** file to the **batch_upgrade** directory.

Step 5 Supplement the password in the **client-info.cfg** file by referring to **Reference Information**.

Upgrade clients in batches.

Step 6 Run the **sh client_batch_upgrade.sh -u -f /tmp/FusionInsight-Client/FusionInsight_Cluster_1_Services_Client.tar -g /tmp/FusionInsight-Client/FusionInsight_Cluster_1_Services_ClientConfig/batch_upgrade/client-info.cfg** command to perform the upgrade.

NOTICE

You are advised to delete the **client-info.cfg** file as soon as possible after the upgrade because the password has been configured.

Step 7 After the upgrade is complete, verify the upgrade result by running the **sh client_batch_upgrade.sh -c** command.

Step 8 If the client is faulty, run the **sh client_batch_upgrade.sh -s** command to roll back the client.

NOTE

- The client batch upgrade tool moves the original client to the backup directory, and then uses the client package specified by the **-f** parameter to install the client. Therefore, if the original client contains customized content, manually save the customized content from the backup directory or move the customized content to the client directory after the upgrade before running the **-c** command. The backup path on the client is *{Original client path}***-backup**.
- The **-u** command is the prerequisite for the **-c** and **-s** commands. You can run the **-c** command to commit the upgrade or the **-s** command to perform a rollback only after the **-u** command is executed to perform an upgrade.
- You can run the **-u** command multiple times to upgrade only the clients that fail to be upgraded.
- The client batch upgrade tool also supports the clients of earlier versions.
- When upgrading a client installed by a non-root user, ensure that the user has the read and write permissions on the directory where the client is located and the parent directory on the target node. Otherwise, the upgrade will fail.
- The client package specified by the **-f** parameter must be a full client package. The client packages of a single component or some components cannot be used as the input.

----End

Reference Information

Before upgrading clients in batches, you need to manually configure the user password for remotely logging in to the client node.

Run the **vi client-info.cfg** command to add a user password.

Example:

```
clientIp,clientPath,user,password
10.10.10.100,/home/omm/client /home/omm/client2,omm,Password
```

The fields in the configuration file are as follows:

- **clientIp**: indicates the IP address of the node where the client is located.

- **clientPath**: indicates the client installation path. Multiple paths are separated by spaces. Note that the path cannot end with a slash (/).
- **user**: indicates the username of the node.
- **password**: indicates the user password of the node.

NOTE

- If the execution fails, view the **node.log** file in the **work_space/log_*XXX*** directory.
- Configuration files containing authentication passwords pose security risks. Delete such files after configuration or store them securely.

10.3.1.7.3 Updating the hosts File in Batches

Scenario

The client package downloaded from FusionInsight Manager contains the client batch upgrade tool. This tool provides the function of upgrading clients in batches and the lightweight function of batch updating the **/etc/hosts** file on the node where the client is located.

Prerequisites

You have made preparations for the upgrade. For details, see "Prepare for the client upgrade." in **Batch Upgrading Clients**.

Updating the hosts File in Batches

Step 1 Check whether the user configured for the node where the **/etc/hosts** file needs to be updated is **root**.

- If yes, go to **Step 2**.
- If no, change the user to **root** and go to **Step 2**.

Step 2 Run the **sh client_batch_upgrade.sh -r -f /tmp/FusionInsight-Client/FusionInsight_Cluster_1_Services_Client.tar -g /tmp/FusionInsight-Client/FusionInsight_Cluster_1_Services_ClientConfig/batch_upgrade/client-info.cfg** command to batch update the **/etc/hosts** file on the nodes where the client resides.

NOTE

- When you batch update the **/etc/hosts** file, the entered client package can be a complete client package or a client package that contains only configuration files (recommended).
- The user configured for the host where the **/etc/hosts** file needs to be updated must be **root**. Otherwise, the update fails.

----End

10.3.2 Managing a Service

10.3.2.1 Overview

Dashboard

Log in to FusionInsight Manager and choose **Cluster** > **Services**. The service management page is displayed, including the functional area and service list.

Functional Area

In the functional area of the service management page, you can select a view type and filter and search for services by service type. You can use the advanced search to select required services based on the running status and configuration status.

Service List

The service list on the service management page contains all installed services in the cluster. If the tile view is selected, the services will be displayed in pane style. If you select the list view, the services will be displayed in a table.

NOTE

In this section, the **Tile View** is used by default.

The service list displays the running status, configuration status, role type, and number of instances of each service. On this page, you can perform some service maintenance tasks, such as starting, stopping, and restarting services.

Table 10-6 Service running status

Status	Description
Normal	Indicates that the service is running properly.
Faulty	Indicates that the service cannot run properly.
Partially Healthy	Indicates that some enhanced functions of the service are abnormal.
Not started	Indicates that the service is stopped.
Unknown	Indicates that the initial status of the service cannot be detected.
Starting	Indicates that the service is being started.
Stopping	Indicates that the service is being stopped.
Failed to start	Indicates that the service fails to be started.
Failed to stop	Indicates that the service fails to be stopped.

NOTE

- If the running status of a service is **Faulty**, an alarm is generated. Rectify the fault based on the alarm information.
- HBase, Hive, Spark, and Loader may be in the **Subhealthy** state.
  - If Yarn is installed but is abnormal, HBase is in the **Subhealthy** state. If the multi-instance function is enabled, all installed HBase service instances are in the **Subhealthy** state.
  - If HBase is installed but is abnormal, Hive, Spark, and Loader are in the **Subhealthy** state.
  - If any HBase instance is installed but is abnormal after the multi-instance function is enabled, Loader is in the **Subhealthy** state.
  - If an HBase instance is installed but is abnormal after the multi-instance function is enabled, the Hive and Spark instances that map to the HBase instance are in the **Subhealthy** state. That is, if HBase 2 is installed but is abnormal, Hive 2 and Spark2 are in the **Subhealthy** state.

Table 10-7 Service configuration status

Status	Description
Synchronized	Indicates that all service parameter settings have taken effect in the cluster.
Expired	Indicates that the latest configuration is not synchronized and does not take effect after the service parameters are modified. You need to synchronize the configurations and restart the services. You can click next to **Configuration Status** to view expired configuration items.
Failed	Indicates that a communication or read/write exception occurs during the parameter configuration synchronization. Use **Synchronize Configuration** to rectify the fault.
Synchronizing	Indicates that the service parameter configuration is being synchronized.
Unknown	Indicates that the initial status of the service cannot be detected.

You can click a service in the service list to perform simple maintenance and management operations on the service, as described in **Table 10-8**.

Table 10-8 Basic maintenance and management

Menu Item on the UI	Description
Start Service	Start a specified service in the cluster.
Stop Service	Stop a specified service in the cluster.

Menu Item on the UI	Description
Restart Service	Restart a specified service in the cluster. **NOTE** If a service is restarted, other services that depend on this service will be unavailable. Therefore, select **Restart upper-layer services**. Determine whether to perform this operation based on the displayed service list. Services are restarted one by one due to their dependency. **Table 10-9** describes the restart duration of a single service.
Service Rolling Restart	Restart a specified service in the cluster without interrupting services. For details about the parameter settings, see **Table 10-4**.
Synchronize Configuration	• Enable new configuration parameters for a specified service in the cluster. • Distribute new configuration parameters for services whose **Configuration Status** is **Expired**. **NOTE** After some services are synchronized, restart the services for the settings to take effect.

Table 10-9 Restart duration

Service	Restart Duration	Startup Duration	Remarks
IoTDB	3 min + x	ConfigNode: 2 min IoTDBServer: 1 min + x	**x** indicates the metadata loading duration of each IoTDBServer instance. It takes about 3 seconds to load 200 GB data. The restart duration is calculated separately when all instances are started at the same time. The service's total restart time depends on the size of the data on the node that has the most data.
CDL	2 min	CDLConnector: 1 min CDLService: 1 min	-
ClickHouse	4 min	ClickHouseServer: 2 min ClickHouseBalancer: 2 min	-

Service	Restart Duration	Startup Duration	Remarks
HDFS	10min+x	NameNode: 4 min + x DataNode: 2 min JournalNode: 2 min Zkfc: 2 min	*x* indicates the NameNode metadata loading duration. It takes about 2 minutes to load 10,000,000 files. For example, *x* is 10 minutes for 50 million files. The startup duration fluctuates with reporting of DataNode data blocks.
Yarn	5 min + x	ResourceManager: 3 min + x NodeManager: 2 min	*x* indicates the time required for restoring ResourceManager reserved tasks. It takes about 1 minute to restore 10,000 reserved tasks.
MapReduce	2 min + x	JobHistoryServer: 2 min + x	*x* indicates the scanning duration of historical tasks. It takes about 2.5 minutes to scan 100,000 tasks.
ZooKeeper	2 min + x	quorumpeer: 2 min + x	*x* indicates the duration for loading znodes. It takes about 1 minute to load 1 million znodes.
Solr	10 min + x	10 min + x	*x* indicates the data restoration duration. It takes about 10 minutes to restore data of 10,000 shards. For example, if there are 150 instances and the data volume increases by 15 TB for every 10,000 shards, the data restoration duration increases by about 15 minutes.
Elasticsearch	10 min + x	5 min + x	*x* indicates the data restoration duration. It takes about 8 minutes to restore data of 10,000 shards.
Hive	3.5 min	HiveServer: 3 min MetaStore: 1 min 30s WebHcat: 1 min Hive service: 3 min	-
Spark	5 min	JobHistory: 5 min SparkResource: 5 min JDBCServer: 5 min	-

Service	Restart Duration	Startup Duration	Remarks
Flink	4 min	FlinkResource: 1 min FlinkServer: 3 min	-
Kafka	2 min + x	Broker: 1 min + x	*x* indicates the data restoration duration. It takes about 2 minutes to start 20,000 partitions for a single instance.
Redis	1 min + x	Redis: 1 min + x	1. The number of instances installed on a single Redis node depends on the number of CPU cores. It takes about one minute to start a single instance. 2. *x* indicates the data restoration duration. It takes about 2 minutes to restore 1 GB data of a single instance from the RDB. It takes about 1 minute to restore 1 GB data of a single instance from AOF.
FTP-Server	1 min	FTP-Server: 1 min	-
Flume	3 min	Flume: 2 min MonitorServer: 1 min	-
RTDService	2 min	RTDServer: 2 min	-
Containers	2 min	WebContainer: 2 min	-
MOTService	30 min	MOTServer:30 min	-
Doris	2 min	FE: 1min BE: 1min DBroker: 1min	-
MemArtsCC	2 min	CCWorker: 1min CCSideCar: 1min	-

10.3.2.2 Other Service Management Operations

10.3.2.2.1 Service Details Page

Overview

Log in to FusionInsight Manager and choose **Cluster** > **Services**. In the service list, click a specified service name to access its details page, including the **Dashboard**, **Instance**, **Instance Groups** and **Configurations** tab pages as well as function areas. For some services, the custom management tool page can be displayed.For details about the supported management tools, see **Table 10-10**..

Table 10-10 Customized management tools

Tool	Service	Description
Flume configuration tool	Flume	Configures collection parameters for the Flume server and client.
Flume client management tool	Flume	Views the monitoring information about the Flume client.
Kafka topic monitoring tool	Kafka	Monitors and manages Kafka topics.
Redis management tool	Redis	Provides a graphical user interface (GUI) for Redis cluster management.
MOTService management tool	MOTService	Provides a GUI for MOTService user management.
Containers management tool	Containers	Provides a GUI for Containers instance management and service governance.

The **Dashboard** page is the default page, which contains the basic information, role list, dependency table, and monitoring chart, and more. You can manage services in the upper right corner. For details about basic service management, such as starting, stopping, rolling restart, and synchronization configuration, see **Table 10-8**. For details about other service management operations, see **Table 10-11**.

Table 10-11 Service management operations

Navigation Path	Description
More > **Health Check**	Performs a health check for the current service. The health check items include the health status of each check object, related alarms, and user-defined monitoring indicators. The check result is not the same as the values of **Running Status** displayed on the GUI. To export the result of the health check, click **Export Report** in the upper left corner of the checklist. If you find any problem, click **View Help**.
More > **Download Client**	Download the default client that contains only specific services and perform management operations, run services, or perform secondary development on the client. For details, see **Downloading the Client**.
More > **Change Service Name**	Changes the name of the current service.
More > **Perform** *XX* **Switchover**	For details, see **Performing Active/Standby Switchover of a Role Instance**.
More > **Enter/Exit Maintenance Mode**	Configures a service to enter/exit the maintenance mode.
Configurations > **Import/Export**	In the scenario where services are migrated to a new cluster or the same services are deployed again, you can import or export all configuration data of a specific service to quickly copy the configuration results.

Basic Information Area

The basic information area on the **Dashboard** tab page contains the basic status data of the service, including the running status, configuration details, version, and key information of the service. If the service supports the open-source web UIs, you can access the open-source web UIs by clicking the links in the basic information area.

NOTE

In the current version, user **admin** does not have the permission to access all the service functions provided on the open source web UI. Create a component service administrator to access the WebUI address.

Role List

The role list on the **Dashboard** tab page contains all roles of the service. The role list displays the running status and the number of instances of each role.

Dependency

The dependency relationship table on the **Dashboard** tab page displays the services on which the current service depends and other services that depend on the service.

Historical Records of Alarms and Events

The alarm and event history area displays the key alarms and events reported by the current service. Up to 20 historical records are displayed.

Chart

The chart area is displayed on the right of the **Dashboard** tab page and contains the key monitoring indicator report of the service. You can customize the monitoring report that is displayed in the chart area, view the description of the monitoring metrics, or export the monitoring data. For a customized resource contribution chart, you can zoom in on the chart and switch between the trend chart and distribution chart.

NOTE

Some services in the cluster provide service-level resource monitoring items. For details, see **Resource Monitoring**.

10.3.2.2.2 Performing Active/Standby Switchover of a Role Instance

Scenario

Some service roles are deployed in active/standby mode. If the active instance needs to be maintained and cannot provide services, or other maintenance is required, you can manually trigger an active/standby switchover.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services**.

Step 3 Click the specified service name on the service management page.

Step 4 On the service details page, expand the **More** drop-down list and select **Perform *Role Instance* Switchover**.

Step 5 In the displayed dialog box, enter the password of the current login user and click **OK**.

Step 6 In the displayed dialog box, click **OK** to perform active/standby switchover for the role instance.

NOTE

- The Manager component package only supports the active/standby switchover of DBService role instances.
- The HD component package supports active/standby switchover of the following service role instances: HDFS, Yarn, HBase, and MapReduce.
- When an active/standby switchover is performed for a NameNode on HDFS, a NameService must be set.
- The Porter component package only supports the active/standby switchover of Loader role instances.
- The RTD component package supports active/standby switchover of RTDService and MOTService role instances.
- This function cannot be used for other role instances.

----End

10.3.2.2.3 Resource Monitoring

Log in to FusionInsight Manager and choose **Cluster** > **Services** > *Target service*. Click **Resource**. The resource monitoring page is displayed.

Some services in the cluster provide service-level resource monitoring metrics. By default, the monitoring data of the latest 12 hours is displayed. You can click to customize a time range. Time range options are **12h**, **1d**, **1w**, and **1m**. You can click to export the corresponding report information. If a monitoring item has no data, the report cannot be exported. **Table 10-12** lists the services and monitoring items that support resource monitoring.

Table 10-12 Service resource monitoring

Service	Metrics	Description
ClickHouse	Part Information	Top 10 tables with the largest number of parts on each ClickHouse node
Elasticsearch	Thread Pool Information	Displays information about the thread pool in an Elasticsearch cluster.
	Index Information	Displays the information about each index in an Elasticsearch cluster.
	User Resource Information	Displays the total number of indexes created by each user in the Elasticsearch cluster, total number of index shards, total number of index documents, and total index storage capacity.
	Index Data Volume	Displays the number of documents and storage data volume of each index in an Elasticsearch cluster.

Service	Metrics	Description
HDFS	Resource Usage (by Tenant)	• Collects statistics on HDFS resource usage by tenant. • Views the metrics **Capacity** or **Number of File Objects**.
	Resource Usage (by User)	• Collects statistics on HDFS resource usage by user. • Views the metrics **Used Capacity** or **Number of File Objects**.
	Resource Usage (by Directory)	• Collects statistics on HDFS resource usage by directory. • Views the metrics **Used Capacity** or **Number of File Objects**. • You can click  to configure space monitoring. Alternatively, you can specify an HDFS file system directory for monitoring.
	Resource Usage (by Replica)	• Collects statistics on HDFS resource usages by replica count. • Views the metrics **Used Capacity** or **File Count**.
	Resource Usage (by File Size)	• Collects statistics on HDFS resource usages by file size. • Views the metrics **Used Capacity** or **File Count**.
	Recycle Bin (by User)	• Collects statistics on the usage of the HDFS recycle bin by user. • Views the metrics **Recycle Bin Capacity** or **Number of File Objects**.
	Operation Count	• Collects the number of operations in HDFS.
	Automatic Balancer	• Collects statistics on the execution speed of HDFS automatic balancer and the total capacity of the current balancer migration.
	NameNode RPC Open Connections (by User)	• Displays the number of connections of each user in the Client RPC requests connected to NameNodes.
	Slow DataNodes	Displays DataNode that transmits or processes data slowly in the cluster.

Service	Metrics	Description
	Slow Disks	Displays the disk that processes data slowly on the DataNode in the cluster.
HBase	Operation Requests in Tables	Displays the number of PUT, DELETE, GET, SCAN, INCREMENT, and APPEND operation requests in all tables on all RegionServers.
	Operation Requests on RegionServers	Displays the number of PUT, DELETE, GET, SCAN, INCREMENT, and APPEND operation requests and number of all operation requests in RegionServer.
	Operation Requests for Service	Displays the number of PUT, DELETE, GET, SCAN, INCREMENT, and APPEND operation requests in all regions on RegionServers.
	HFiles on RegionServers	Displays the number of HFiles in all RegionServers.
HetuEngine	Coordinator Resource Usage	Displays the coordinator resource usage in the selected queue.
	Coordinator Resource Usage Ratio	Displays the coordinator resource usage in the selected queue.
	Worker Resource Usage	Displays the worker resource usage in the selected queue.
	Worker Resource Usage Ratio	Displays the worker resource usage in the selected queue.
	Number of Coordinators and Workers	Displays the number of coordinators and workers in the selected queue.
Hive	HiveServer2-Background-Pool Threads (by IP)	Displays the number of HiveServer2-Background-Pool threads of top users. These threads are measured and displayed in a measurement period.
	HiveServer2-Handler-Pool Threads (by IP)	Displays the number of HiveServer2-Handler-Pools of top users collected and displayed in a period.
	Used MetaStore Number (by IP)	Collects statistics on and displays the MetaStore usage of top users in a period.
	Number of Hive jobs	Displays the number of user-related jobs collected by Hive in a period.

Service	Metrics	Description
	Number of Files Accessed in the Split Phase	Displays the number of files accessed by the underlying file storage system (HDFS by default) in the Split phase in a period.
	Hive Basic Operation Time	Collects time for creating a directory (mkdirTime), creating a file (touchTime), writing a file (writeFileTime), renaming a file (renameTime), moving a file (moveTime), deleting a file (deleteFileTime), and deleting a directory (deleteCatalogTime) in a period of time.
	Table Partitions	Displays the number of partitions in all Hive tables, which is displayed in the following format: *database # table name*, *number of table partitions*.
	HQL Map Count	Collects statistics on HQL statements executed in a period and the number of Map statements invoked during the execution. The displayed information includes users, HQL statements, and the number of Map statements.
	HQL Access Statistics	Displays the number of HQL access times in a period.
Kafka	Kafka Disk Usage Distribution	Displays the disk usage distribution statistics of the Kafka cluster.
Spark	HQL Access Statistics	Collects HQL access statistics in a period, including the username, HQL statement, and HQL statement execution times.
Yarn	Used resources (by task)	• Displays the number of CPU cores and memory used by a task. • Views the metrics **By memory** or **By CPU**.
	Resource usage (by tenant)	• Displays the number of CPU cores and memory used by a tenant. • Views the metrics **By memory** or **By CPU**.

Service	Metrics	Description
	Resource usage ratio (by tenant)	• Displays the ratio of the number of CPU cores to the memory used by a tenant. • Views the metrics **By memory** or **By CPU**.
	Task Duration Ranking	Displays Yarn tasks sorted by time consumption.
	ResourceManager RPC Open Connections (by User)	Displays the number of client RPC connections to ResourceManager by user.
	Operation Count	Collects statistics on the number and proportion of operations corresponding to each Yarn operation type.
	Ranking of Tasks in a Queue by Resource Usage	• Displays the resources consumed by the tasks running in a queue after the queue (tenant) is selected on the GUI. • Views the metrics **By memory** or **By CPU**.
	Ranking of Users in a Queue by Resource Usage	• Displays the resources consumed by the users who are running tasks in the queue after a queue (tenant) is selected on the GUI. • Views the metrics **By memory** or **By CPU**.
ZooKeeper	Used Resources (By Second-Level Znode)	• Displays the ZooKeeper level-2 znode resource status. • Views the metrics **By Znode quantity** or **By capacity**.
	Number of Connections (by Client IP Address)	Displays the ZooKeeper client connection resource status.

10.3.2.2.4 Collecting Stack Information

Scenario

To meet actual service requirements, the cluster administrator can collect stack information about a specified role or instance on FusionInsight Manager, save the information to a local directory, and download the information. The following information can be collected:

1. jstack information.

2. jmap -histo information.
3. jmap -dump information.
4. Thr jstack and jmap-histo information can be collected continuously for comparison.

Procedure

Collecting stack information

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services** > *Name of the service whose stack information is to be collected*.

Step 3 On the displayed page, Choose **More** > **Collect Stack Information**.

NOTE

- To collect stack information of multiple instances, go to the instance list, select the desired instances in the instance list and choose **More** > **Collect Stack Information**.
- To collect stack information of a single instance, click the desired instance and choose **More** > **Collect Stack Information**.

Step 4 In the displayed dialog box, select the desired role and content, configure advanced options (retain the default settings if there is no special requirement), and click **OK**.

Step 5 After the collection is successful, click **Download**.

Downloading Stack Information

Step 6 Choose **Cluster** > **Services** > *Name of the service whose stack information is to be downloaded*. Choose **More** > **Download Stack Information** in the upper right corner.

Step 7 Select the desired role and content and click **Download** to download the stack information to the local PC.

Clearing stack information

Step 8 Choose **Cluster** > **Services** > *Name of the service whose stack information is to be cleared*.

Step 9 Choose **More** > **Clear Stack Information** in the upper right corner.

Step 10 Select the desired role and content and configure **File Directory**. Click **OK**.

----End

10.3.2.2.5 Switching Ranger Authentication

Scenario

By default, the Ranger service is installed and Ranger authentication is enabled for a newly installed cluster in security mode. You can set fine-grained security access policies for accessing component resources through the permission plug-in of the component. If Ranger authentication is not required, the cluster administrator can manually disable Ranger authentication on the service page. After Ranger

authentication is disabled, the system continues to perform permission control based on the role model of FusionInsight Manager when accessing component resources.

In a cluster upgraded from an earlier version, Ranger authentication is not used by default when users access component resources. The cluster administrator can manually enable Ranger authentication after installing the Ranger service.

NOTE

- In a cluster in security mode, the following components support Ranger authentication: HDFS, Yarn, Kafka, Hive, HBase, Elasticsearch, HetuEngine, CDL, and Spark.
- In a cluster in non-security mode, Ranger authentication can be used to perform permission control by OS users on components such as HBase, HDFS, Hive, Spark, and Yarn.
- After Ranger authentication is enabled, all authentication of the component will be managed by Ranger. The permissions set by the original authentication plug-in will become invalid (The ACL rules of HDFS and Yarn components still take effect). Exercise caution when performing this operation. You are advised to deploy permissions on Ranger in advance.
- After Ranger authentication is disabled, all authentication of the component will be managed by the permission plug-in of the component. The permission set on Ranger will become invalid. Exercise caution when performing this operation. You are advised to deploy permissions on Manager in advance.

Enabling Ranger Authentication

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services**.

Step 3 Click the specified service name on the service management page.

Step 4 On the service details page, expand the **More** drop-down list and select **Enable Ranger**.

Step 5 In the displayed dialog box, enter the password of the current login user and click **OK**.

Step 6 In the service list, restart the service whose configuration has expired.

----End

Disabling Ranger Authentication

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services**.

Step 3 Click the specified service name on the service management page.

Step 4 On the service details page, expand the **More** drop-down list and select **Disable Ranger**.

Step 5 Enter the password of the current login user and click **OK**. In the displayed dialog box, click **OK**.

Step 6 In the service list, restart the service whose configuration has expired.

----End

10.3.2.3 Service Configuration

10.3.2.3.1 Modifying Service Configuration Parameters

Scenario

To meet actual service requirements, cluster administrators can quickly view and modify default service configurations on FusionInsight Manager. Configure parameters based on the information provided in the configuration description.

NOTE

The parameters of DBService cannot be modified when only one DBService role instance exists in the cluster.

Impact on the System

- After configuring properties of a service, you need to restart the service if the service status is **Expired**. The service is unavailable during the restart.
- After the service configuration parameters are modified and then take effect after restart, you need to download and install the client again or download the configuration file to update the client. For example, you can modify configuration parameters of the following services: HBase, HDFS, Hive, Spark, Yarn, and MapReduce.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services**.

Step 3 Click the specified service name on the service management page.

Step 4 Click **Configuration**.

The **Basic Configuration** page is displayed by default. To modify more parameters, click the **All Configurations** tab. The navigation tree displays all configuration parameters of the service. The level-1 nodes in the navigation tree are service names or role names. The parameter category is displayed after the level-1 node is expanded.

Step 5 In the navigation tree, select the specified parameter category and change the parameter values on the right.

NOTE

Select a port parameter value from the value range on the right. Ensure that all parameter values in the same service are within the value range and are unique. Otherwise, the service fails to be started.

If you are not sure about the location of a parameter, you can enter the parameter name in search box in the upper right corner. The system searches for the parameter in real time and displays the result.

Step 6 Click **Save**. In the confirmation dialog box, click **OK**.

Wait until the message "Operation succeeded." is displayed. Click **Finish**.

The configuration is modified.

NOTE

- To update the queue configuration of the Yarn service without restarting service, choose **More** > **Refresh Queue** to update the queue for the configuration to take effect.
- During configuration of the **flume.config.file** parameter, you can upload and download files. After a configuration file is uploaded, the old file will be overwritten. If the configuration is not saved and the service is restarted, the configuration does not take effect. Save the configuration in time.
- If you need to restart the service for the configuration to take effect after modifying service configuration parameters, choose **More** > **Restart Service** in the upper right corner of the service page.
- If the  is displayed before a parameter, this parameter takes effect dynamically. After the configuration is saved, the parameter value is automatically updated to the configuration file.

----End

10.3.2.3.2 Modifying Custom Configuration Parameters of a Service

Scenario

MRS cluster components support all open source parameters. Parameters in some key application scenarios can be modified on FusionInsight Manager, and the clients of some components may not contain all parameters of open source features. To modify the component parameters that are not directly supported by Manager, cluster administrators can add new parameters for components using the configuration customization function on Manager. Newly added parameters are saved in component configuration files and take effect after restart.

Impact on the System

- After configuring properties of a service, you need to restart the service if the service status is **Expired**. The service is unavailable during the restart.
- After the service configuration parameters are modified and then take effect after restart, you need to download and install the client again or download the configuration file to update the client.

Prerequisites

Cluster administrators have fully understood the meanings of the parameters to be added, configuration files to take effect, and the impact on components.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services**.

Step 3 Click the specified service name on the service management page.

Step 4 Click **Configuration** and click **All Configurations**.

Step 5 In the navigation tree on the left, locate a level-1 node and select **Customization**. The system displays the customized parameters of the current component.

The configuration files that save the newly added custom parameters are displayed in the **Parameter File** column. Different configuration files may have same open source parameters. After the parameters in different files are set to different values, the configuration takes effect depends on the loading sequence of the configuration files by components. You can customize parameters for services and roles as required. Adding customized parameters for a single role instance is not supported.

Step 6 Locate the row where a specified parameter resides, enter the parameter name supported by the component in the **Name** column and enter the parameter value in the **Value** column.

You can click **+** or **-** to add or delete a customized parameter.

Step 7 Click **Save**. In the displayed **Save Configuration** dialog box, confirm the modification and click **OK**. After the system displays "Operation succeeded", click **Finish**. The configuration is saved successfully.

Restart the expired service or instance for the configuration to take effect.

NOTE

If the  is displayed before a parameter, this parameter takes effect dynamically. After the configuration is saved, the parameter value is automatically updated to the configuration file.

----End

Task Example (Configuring Customized Hive Parameters)

Hive depends on HDFS. By default, Hive accesses the HDFS client. The configuration parameters that have taken effect are controlled by HDFS. For example, the HDFS parameter **ipc.client.rpc.timeout** affects the RPC timeout interval for all clients to connect to the HDFS server. Cluster administrators can modify the timeout interval for Hive to connect to HDFS by configuring custom parameters. After this parameter is added to the **core-site.xml** file of Hive, this parameter can be identified by the Hive service and its configuration overwrites the parameter configuration in HDFS.

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services**.

Step 2 On the displayed page, click **Configuration** and click **All Configurations**.

Step 3 In the navigation tree on the left, select **Customization** for the Hive service. The system displays the custom service parameters supported by Hive.

Step 4 In **core-site.xml**, locate the row that contains the **core.site.customized.configs** parameter, enter **ipc.client.rpc.timeout** in the **Name** column, and enter a new value in the **Value** column, for example, 150000. The unit is ms.

Step 5 Click **Save**. In the displayed **Save Configuration** dialog box, confirm the modification and click **OK**. Wait until the message "Operation succeeded" is displayed, and click **Finish**.

The configuration is saved successfully.

After the configuration is saved, restart the expired service or instance for the configuration to take effect.

----End

10.3.3 Instance Management

10.3.3.1 Overview

Overview

Log in to FusionInsight Manager and choose **Cluster** > **Services** > **KrbServer**. On the displayed page, click **Instance**. The instance management page is displayed, including the function area and role instance list.

Functional Area

After selecting the instances to be operated in the function area, you can maintain and manage the role instances, such as starting or stopping the instances. **Table 10-13** shows the main operations.

Table 10-13 Instance maintenance and management

UI Portal	Description
Start Instance	Start a specified instance in the cluster. You can start a role instance in the **Not Started**, **Stop Failed**, or **Startup Failed** state to use the role instance.
More > Stop Instance	Stop a specified instance in the cluster. You can stop a role instance that is no longer used or is abnormal.
More > Restart Instance	Restart a specified instance in the cluster. You can restart an abnormal role instance to restore it.
More > Instance Rolling Restart	Restart a specified instance in the cluster without interrupting services. For details about the parameter settings, see **Performing a Rolling Restart of a Cluster**.

UI Portal	Description
More > Decommission/ Recommission	Recommission or decommission a specified instance in the cluster to change the service availability status of the service. For details, see **Decommissioning and Recommissioning an Instance**. **NOTE** Only the role DataNode in HDFS, role NodeManager in Yarn, role EsNode in Elasticsearch, and role ClickHouseServer in ClickHouse, and role RegionServer in HBase support the recommissioning and decommissioning functions.
Desired instance > **More** > **Synchronize Configuration**	If the **Configuration Status** of a role instance is **Expired**, the role instance has not been restarted after the configuration is modified, and the new configuration is saved only on FusionInsight Manager. In this case, use this function to deliver the new configuration to the specified instance. **NOTE** • After synchronizing the role instance configuration, you need to restart the role instance whose configuration has expired. The role instance is unavailable during the restart. • After the synchronization is complete, restart the instance for the configuration to take effect.
Desired instance > **Instance Configurations**	For details, see **Managing Instance Configurations**.

You can filter instances based on the role they belong to or their running status in the function area.

NOTE

Click **Advanced Search** to search for specified instances by specifying other filter criteria, such as **Host Name**, **Management IP Address**, **Business IP Address**, or **Instance Groups**.

Role Instance List

The role instance list contains the instances of all roles in the cluster. The list displays the running status, configuration status, hosts, and related IP addresses of each instance.

Table 10-14 Instance running status

Status	Description
Normal	Indicates that the instance is running properly.
Faulty	Indicates that the instance cannot run properly.

Status	Description
Decommissioned	Indicates that the instance is out of service.
Not started	Indicates that the instance is stopped.
Unknown	Indicates that the initial status of the instance cannot be detected.
Starting	Indicates that the instance is being started.
Stopping	Indicates that the instance is being stopped.
Restoring	Indicates that an exception may occur in the instance and the instance is being automatically rectified.
Decommissioning	Indicates that the instance is being decommissioned.
Recommissioning	Indicates that the instance is being recommissioned.
Failed to start	Indicates that the service fails to be started.
Failed to stop	Indicates that the service fails to be stopped.

Instance Details

You can click an instance name to go to the instance details page and view the basic information, configuration file, instance logs, and monitoring metric reports of the instance.

10.3.3.2 Decommissioning and Recommissioning an Instance

Scenario

Some role instances provide services for external services in distributed and parallel mode. Services independently store information about whether each instance can be used. Therefore, you need to use FusionInsight Manager to recommission or decommission these instances to change the instance running status.

Some instances do not support the recommissioning and decommissioning functions.

NOTE

The following roles support decommissioning and recommissioning: HDFS DataNode, Yarn NodeManager, Elasticsearch EsNode*N*, ClickHouse ClickHouseServer, IoTDB IoTDBServer, Doris BE, and HBase RegionServer.

- By default, if the number of the DataNodes is less than or equal to that of HDFS replicas, decommissioning cannot be performed. If the number of HDFS replicas is three and the number of DataNodes is less than four in the system, decommissioning cannot be performed. In this case, an error will be reported and force FusionInsight Manager to exit the decommissioning 30 minutes after FusionInsight Manager attempts to perform the decommissioning.
- You can enable quick decommissioning before decommissioning DataNodes. In this case, when the number of DataNodes meets the value of **dfs.namenode.decommission.force.replication.min**, the system decommissions the nodes and adds HDFS copies at the same time. **If data is written during quick decommissioning, data may be lost. Exercise caution when performing this operation.** The following table lists the parameters related to quick decommissioning. You can search for and view the parameters on the HDFS configuration page on FusionInsight Manager.

  dfs.namenode.decommission.force.enabled: Whether to enable quick decommissioning for DataNode. If this parameter is set to **true**, the function is enabled.

  dfs.namenode.decommission.force.replication.min: minimum number of available copies of a block required for DataNode quick decommissioning. The value ranges from 1 to 3.
- During MapReduce task execution, files with 10 replicas are generated. Therefore, if the number of DataNode instances is less than 10, decommissioning cannot be performed.
- If the number of DataNode racks (the number of racks is determined by the number of racks configured for each DataNode) is greater than 1 before the decommissioning, and after some DataNodes are decommissioned, that of the remaining DataNodes changes to 1, the decommissioning will fail. Therefore, before decommissioning DataNode instances, you need to evaluate the impact of decommissioning on the number of racks to adjust the DataNodes to be decommissioned.
- If multiple DataNodes are decommissioned at the same time, and each of them stores a large volume of data, the DataNodes may fail to be decommissioned due to timeout. To avoid this problem, it is recommended that one DataNode be decommissioned each time and multiple decommissioning operations be performed.
- Before decommissioning ClickHouseServer, perform the pre-decommissioning check. The restrictions on decommissioning or recommissioning are as follows:
  - **Cluster scale**

    If a cluster has only one shard, the instance nodes cannot be decommissioned.

    Multiple instance nodes in the same shard **must be decommissioned or recommissioned at the same time**.

    The cluster shard information can be queried by running the **select cluster,shard_num,replica_num,host_name from system.clusters;** SQL statement.
  - **Cluster storage space**

    Before decommissioning, ensure that the disk space of non-decommissioned nodes is sufficient for storing data of all decommissioned nodes. In addition, the non-decommissioned nodes must have about 10% redundant storage space after decommissioning to ensure that the remaining instances can run properly after decommissioning.
  - **Cluster status**

If a faulty ClickHouseServer instance node exists among the nodes to be decommissioned and non-decommissioned nodes in the cluster, all instance nodes cannot be decommissioned.

- **Database**

  If a database exists only on an instance node to be decommissioned, the instance node cannot be decommissioned. You need to create the database on all ClickHouseServer instance nodes in the cluster.

  Do not create, delete, or rename a database during the decommissioning process.

- **Local non-replication table**

  If a local non-replication table exists only on an instance node to be decommissioned, the instance node cannot be decommissioned. You need to create a local non-replication table with the same name on any node that has not been decommissioned.

  For example, the current cluster has two shards, shard 1 has two nodes A and B, and shard 2 has two nodes C and D. The non-replication table **test** does not carry the **ON CLUSTER** keyword when it is created, and the table is created only on node A.

  In this case, nodes A and B in shard 1 need cannot be decommissioned. You need to create the table **test** on node C or D in shard 2 before decommissioning A and B.

- **Replication table**

  If a replication table exists only on some instance nodes in a cluster, the instance nodes cannot be decommissioned. You need to manually create the replication table on all instance nodes where the replication table does not exist in the cluster before decommissioning.

  For example, the current cluster has two shards, shard 1 has two nodes A and B, and shard 2 has two nodes C and D. The replication table **test** does not carry the **ON CLUSTER** keyword when it is created, and the table is created only on nodes A and B.

  In this case, nodes A and B in shard 1 need cannot be decommissioned. You need to create the table **test** on nodes C and D in shard 2 before decommissioning A and B.

- **Distributed table**

  Decommissioning does not support automatic migration of distributed tables. You are advised to recreate distributed tables on non-decommissioned nodes before decommissioning. Rebuilding distributed tables on non-decommissioned nodes before decommissioning does not affect decommissioning, but may affect subsequent service operations.

- **Materialized view**

  Decommissioning does not support automatic migration of materialized views. You are advised to recreate materialized views on non-decommissioned nodes before decommissioning. If the materialized view of a node to be decommissioned does not display the specified aggregation table but uses an embedded table, the node cannot be decommissioned.

- **Configuration synchronization**

  Before and after decommissioning or recommissioning, you need to synchronize the configuration to ensure data consistency.

- **Detached data**

  If the table on a node to be decommissioned has been detached and data still exists in the detached directory, the node cannot be decommissioned. You need to perform the attach operation to process the data in the detached directory before decommissioning.

- **Distributed table writes**

Before decommissioning, check whether distributed table writing services exist on the service side. If it exists, stop the distributed table writing service before decommissioning. Otherwise, the decommissioning process will loop and fail.

- **Tables and views**

  Do not create, delete, or rename tables or views during decommissioning.

- If the number of IoTDBServers is less than or equal to the number of region copies configured for the cluster (3 by default), decommissioning cannot be performed.
- Decommissioning or recommissioning constraints for Doris BE nodes
  - After decommissioning, the remaining normal BE nodes must be no less than the copies of any table. Otherwise, decommissioning will fail.
  - **BE node storage space**

    Before cluster decommissioning, the disk space of non-decommissioned BE nodes in the cluster must be enough to store data of all BE nodes to be decommissioned. About 10% of the storage space of each non-decommissioned BE node must be reserved after decommissioning to ensure that the remaining instances can run properly.

Procedure

Step 1 Perform the following steps to perform a health check for the DataNodes before decommissioning:

1. Log in to the client installation node as a client user and switch to the client installation directory.
2. For a security cluster, use user **hdfs** for permission authentication.

   ```
   source bigdata_env          #Configure client environment variables.
   kinit hdfs                  #Configure kinit authentication.
   Password for hdfs@HADOOP.COM:    #Enter the login password of user hdfs.
   ```

3. Run the **hdfs fsck / -list-corruptfileblocks** command, and check the returned result.
   - If "has 0 CORRUPT files" is displayed, go to **Step 2**.
   - If the result does not contain "has 0 CORRUPT files" and the name of the damaged file is returned, go to **Step 1.4**.
4. Run the **hdfs dfs -rm** *Name of the damaged file* command to delete the damaged file.

   NOTE

   Deleting a file or folder is a high-risk operation. Ensure that the file or folder is no longer required before performing this operation.

Step 2 Log in to FusionInsight Manager.

Step 3 Choose **Cluster** > **Services**.

Step 4 Click the specified service name on the service management page. On the displayed page, click the **Instance** tab.

Step 5 Select the specified role instance to be decommissioned.

Step 6 Select **Decommission** or **Recommission** from the **More** drop-down list.

In the displayed dialog box, enter the password of the current login user and click **OK**.

Select **I confirm to decommission these instances and accept the consequence of service performance deterioration** and click **OK** to perform the corresponding operation.

NOTE

During the instance decommissioning, if the service corresponding to the instance is restarted in the cluster using another browser, FusionInsight Manager displays a message indicating that the instance decommissioning is stopped, but the operating status of the instance is displayed as **Started**. In this case, the instance has been decommissioned on the background. You need to decommission the instance again to synchronize the operating status.

----End

10.3.3.3 Managing Instance Configurations

Scenario

Configuration parameters of each role instance can be modified. In the scenario where instances are migrated to a new cluster or the service is redeployed, the cluster administrator can import or export all configuration data of a service on FusionInsight Manager to quickly copy configuration results.

FusionInsight Manager can manage configuration parameters of a single role instance. Modifying configuration parameters and importing or exporting instance configurations do not affect other instances.

Impact on the System

After modifying the configuration of a role instance, you need to restart the instance if the instance status is **Expired**. The role instance is unavailable during restart.

Modifying Instance Configuration

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services**.

Step 3 On the page that is displayed, click the **Instance** tab.

Step 4 Click the specified instance and select **Instance Configuration**.

By default, **Basic Configuration** is displayed. To modify more parameters, click **All Configurations**. All parameter categories supported by the instance are displayed on the **All Configurations** tab page.

Step 5 In the navigation tree, select the specified parameter category and change the parameter values on the right.

If you are not sure about the location of a parameter, you can enter the parameter name in search box in the upper right corner. The system searches for the parameter in real time and displays the result.

Step 6 Click **Save**. In the confirmation dialog box, click **OK**.

Wait until the message "Operation succeeded." is displayed. Click **Finish**.

The configuration is modified.

NOTE

After the configuration parameters of a role instance are modified, you need to restart the instance if the instance status is **Expired**. You can select the expired instance on the **Instances** page and choose **More** > **Restart Instance**.

If the  is displayed before a parameter, this parameter takes effect dynamically. After the configuration is saved, the parameter value is automatically updated to the configuration file.

----End

Exporting/Importing Instance Configuration

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services**.

Step 3 Click the specified service name on the service management page. On the displayed page, click the **Instance** tab.

Step 4 Click the specified instance and select **Instance Configurations**.

Step 5 Click **Export** to export the configuration parameter file to the local host.

Step 6 On the **Instance Configurations** page, click **Import**, select the configuration parameter file of the instance, and import the file.

----End

10.3.3.4 Viewing the Instance Configuration File

Scenario

FusionInsight Manager allows O&M personnel to view the content configuration files such as environment variables and role configurations of the instance node on the management page. If O&M personnel need to quickly check whether configuration items of the instance are incorrectly configured or when some hidden configuration items need to be viewed, the O&M personnel can directly view the configuration files on FusionInsight Manager. In this case, users quickly analyze configuration problems.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services**.

Step 3 Click the specified service name on the service management page. On the displayed page, click the **Instance** tab.

Step 4 Click the name of the target instance. In the **Configuration File** area on the **Instance Status** page, the configuration file list of the instance is displayed.

Step 5 Click the name of the configuration file to be viewed to view the parameter values in the configuration file.

To obtain the configuration file, you can download the configuration file to the local PC.

NOTE

If a node in the cluster is faulty, the configuration file cannot be viewed. Rectify the fault before viewing the configuration file again.

----End

10.3.3.5 Instance Group

10.3.3.5.1 Managing Instance Groups

Scenario

Instance groups can be managed on FusionInsight Manager. That is, you can group multiple instances in the same role based on a specified principle, such as the nodes with the same hardware configuration. The modification on the configuration parameters of an instance group applies to all instances in the group.

In a large cluster, instance groups are used to improve the capability of managing instances in batches in the heterogeneous environment. After instances are grouped, the instances can be configured repeatedly to reduce redundant instance configuration items and improve system performance.

Creating an Instance Group

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services**.

Step 3 Click the specified service name on the service management page.

Step 4 On the displayed page, click the **Instance Groups** tab.

Click  and configure parameters as prompted.

Table 10-15 Instance group configuration parameters

Parameter	Description
The group name	Indicates the instance group name. The value can contain only letters, digits, underscores (_), hyphens (-), and spaces. It must start with a letter, digit, underscore (_), or hyphen (-) and cannot ends with a space. It can contain a maximum of 99 characters.
Role	Indicates the role to which an instance group belongs.
Copy From	Indicates that the parameter values of a specified instance group are copied to the parameters of a new group. If the value is null, the default values are used for the parameters of the new group.

Parameter	Description
Description	Indicates the instance group description. It can contain only letters, digits, commas (,), periods (.), underscores (_), spaces, and line breaks, and can contain a maximum of 200 characters.

NOTE

- Each instance must belong to only one instance group. When an instance is installed for the first time, it belongs to the instance group *Role name*-**DEFAULT** by default.
- You can delete unnecessary or unused instance groups. Before deleting an instance group, migrate all instances in the group to other instance groups, and then delete the instance group by referring to **Deleting an Instance Group**. The default instance group cannot be deleted.

Step 5 Click **OK**.

The instance group is created.

----End

Modifying Properties of an Instance Group

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services**.

Step 3 Click the specified service name on the service management page.

Step 4 Click the **Instance Groups** tab. On the **Instance Groups** tab page, locate the row that contains the target instance group.

Click and modify parameters as prompted.

Step 5 Click **OK** to save the modifications.

The default instance group cannot be modified.

----End

Deleting an Instance Group

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services**.

Step 3 Click the specified service name on the service management page.

Step 4 Click the **Instance Groups** tab. On the **Instance Groups** tab page, locate the row that contains the target instance group.

Step 5 Click .

Step 6 In the displayed dialog box, click **OK**.

The default instance group cannot be deleted.

----End

10.3.3.5.2 Viewing Information About an Instance Group

Scenario

The cluster administrator can view the instance group of a specified service on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services**.

Step 3 Click the specified service name on the service management page.

Step 4 On the displayed page, click the **Instance Groups** tab.

Step 5 In the navigation tree, select a role. On the **Basic** tab page, view all instances in the instance group.

NOTE

To move an instance from an instance group to another, perform the following operations:

1. Select the instance to be moved and click **Move**.
2. In the displayed dialog box, select an instance group to which the instance to be moved.

   During the migration, the configuration of the new instance group is automatically inherited. If the instance configuration is modified before the migration, the configuration of the instance prevails.
3. Click **OK**.

   Restart the expired service or instance for the configuration to take effect.

----End

10.3.3.5.3 Configuring Instantiation Group Parameters

Scenario

In a large cluster, users can configure parameters for multiple instances in batches by configuring the related instance groups on FusionInsight Manager, reducing redundant instance configuration items and improving system performance.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services**.

Step 3 Click the specified service name on the service management page.

Step 4 On the displayed page, click the **Instance Groups** tab.

Step 5 In the navigation tree, select the instance group name of a role, and switch to the **Configuration** tab page. Adjust parameters to be modified, and click **Save**. The configuration takes effect for all instances in the instance group.

----End

10.4 Hosts

10.4.1 Host Management Page

10.4.1.1 Viewing the Host List

Overview

Log in to FusionInsight Manager, click **Hosts**, and the host list is displayed on the host management page. You can view the host list and basic information of each host.

You can switch view types and set search criteria to filter and search for hosts.

Host View

You can click **Role View** to view the roles deployed on each host. If the role supports the active/standby mode, the role name is displayed in bold.

Host List

The host list on the host management page contains all hosts in the cluster and allows you to perform O&M operations on the hosts.

On the host management page, you can filter hosts by node type. The filtering rules are as follows:

- A management node is the node where OMS is deployed. Additionally, control roles and data roles may also be deployed on management nodes.
- A control node is the node where control roles are deployed. Additionally, data roles may also be deployed on control nodes.
- A Data Node is the node where only data roles are deployed.

If you select the **Host View**, the IP address, rack planning, AZ name, running status, cluster name, and hardware resource usage of each host are displayed.

Table 10-16 Host running status

Status	Description
Normal	Indicates that the host is in the normal state.
Faulty	Indicates that the host is abnormal.

Status	Description
Unknown	Indicates that the initial status of the host cannot be detected.
Isolated	Indicates that the host is isolated.
Suspended	Indicates that the host is stopped.

10.4.1.2 Viewing the Host Dashboard

Overview

Log in to FusionInsight Manager, click **Hosts**, and click a host name in the host list. The host details page contains the basic information area, disk status area, role list area, and monitoring chart.

Basic Information Area

The basic information area contains the key information about the host, such as the management IP address, service IP address, host type, rack, firewall, number of CPU cores, and OS.

Disk Status Area

The disk status area contains all disk partitions configured for the cluster on the host and the usage of each disk partition.

Instance List Area

The instance list area displays all role instances installed on the host and the status of each role instance. You can click the log file next to a role instance name to view the log file content of the instance online.

Alarm and Event History

The alarm and event history area displays the key alarms and events reported by the current host. The system can display a maximum of 20 historical records.

Chart

The monitoring chart area is displayed on the right of the host details page, and contains the key monitoring metrics of the host.

You can choose ▼ > **Customize** in the upper right corner to customize the monitoring reports to be displayed in the chart area. Select a time range and choose ▼ > **Export** to export detailed monitoring metric data within the specified time range.

You can click  next to the title of a monitoring indicator to open the description of the monitoring indicator.

Click the **Chart** tab of the host to view the full monitoring chart information about the host.

10.4.1.3 Checking Host Processes and Resources

Overview

Log in to FusionInsight Manager, click **Hosts**, and click the specified host name in the host list. On the host details page, click the **Process** and **Resource** tabs.

Host Process

On the **Process** tab page, the information about the role processes of the deployed service instances on the current host is displayed, including the process status, PID, and process running time. You can directly view the log files of each process online.

Host Resource

On the **Resource** tab page, the detailed resource usage of deployed service instances on the current host is displayed, including the CPU, memory, disk, and port usage.

10.4.2 Host Maintenance Operations

10.4.2.1 Starting and Stopping All Instances on a Host

Scenario

If a host is faulty, you may need to stop all the roles on the host and perform maintenance check on the host. After the host fault is rectified, start all roles running on the host to recover host services. You can start or stop all instances on a host on the host management page or host details page on FusionInsight Manager. The following describes how to perform such operations on the host management page.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Click **Hosts**.

Step 3 Select the check box of the target host.

Step 4 Select **Start All Instances** or **Stop All Instances** from the **More** drop-down list to start or stop all role instances.

----End

10.4.2.2 Performing a Host Health Check

Scenario

If the running status of a host is not **Normal**, you can perform health checks on the host to check whether some basic functions are abnormal. During routine O&M, you can perform host health checks to ensure that the configuration parameters and monitoring of each role instance on the host are normal and can run stably for a long time.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Click **Hosts**.

Step 3 Select the check box of the target host.

Step 4 Select **Health Check** from the **More** drop-down list to start the health check.

To export the result of the health check, click **Export Report** in the upper left corner. If any problem is detected, click **Help**.

----End

10.4.2.3 Configuring Racks for Hosts

Scenario

All hosts in a large cluster are usually deployed on multiple racks. Hosts on different racks communicate with each other through switches. The network bandwidth between different hosts on the same rack is much greater than that on different racks. In this case, plan the network topology based on the following requirements:

- To improve the communication speed, it is recommended that data be exchanged between hosts on the same rack.
- To improve the fault tolerance capability, distribute processes or data of distributed services on different hosts of multiple racks as dispersedly as possible.

Hadoop uses a file directory structure to represent hosts.

The HDFS cannot automatically determine the network topology of each DataNode in the cluster. You need to set the rack name to identify the rack where the host is located so that the NameNode can draw the network topology of the required DataNodes and back up data of the DataNodes to different racks. Similarly, Yarn needs to obtain rack information and allocate tasks to different NodeManagers as required.

If the cluster network topology changes, you need to reallocate racks for hosts on FusionInsight Manager so that related services can be automatically adjusted.

Impact on the System

If the name of the host rack is changed, storage policy for HDFS replicas, Yarn task assignment, and storage location of Kafka partitions will be affected. After the

modification, you need to restart the HDFS, Yarn, and Kafka for the configuration to take effect.

Improper rack configuration will unbalance loads (including CPU, memory, disk, and network) among nodes in the cluster, which decreases the cluster reliability and stability. Therefore, before allocating racks, take all aspects into consideration and properly set racks.

Rack Allocation Policies

NOTE

Physical rack: indicates the real rack where the host resides.

Logical rack: indicates the rack name of the host on FusionInsight Manager.

Policy 1: Each logical rack has nearly the same number of hosts.

Policy 2: The name of the logical rack of the host must comply with that of the physical rack to which the host belongs.

Policy 3: If there are only few hosts on a physical rack, combine this physical rack and other physical racks with few hosts into a logical rack, which complies with policy 1. Hosts in two equipment rooms cannot be placed in one logical rack. Otherwise, performance problems may be caused.

Policy 4: If there are lots of hosts on a physical rack, divide these hosts into multiple logical racks, which complies with policy 1. Hosts with great differences should not be placed in the same logical rack. Otherwise, the cluster reliability will be decreased.

Policy 5: You are advised to set **default** or other values for logical racks on the first layer, and the values in the same cluster must be consistent.

Policy 6: The number of hosts in each rack cannot be less than 3.

Policy 7: A cluster can contain at most 50 logical racks. If there are too many logical racks in a cluster, the maintenance is difficult.

Best Practices

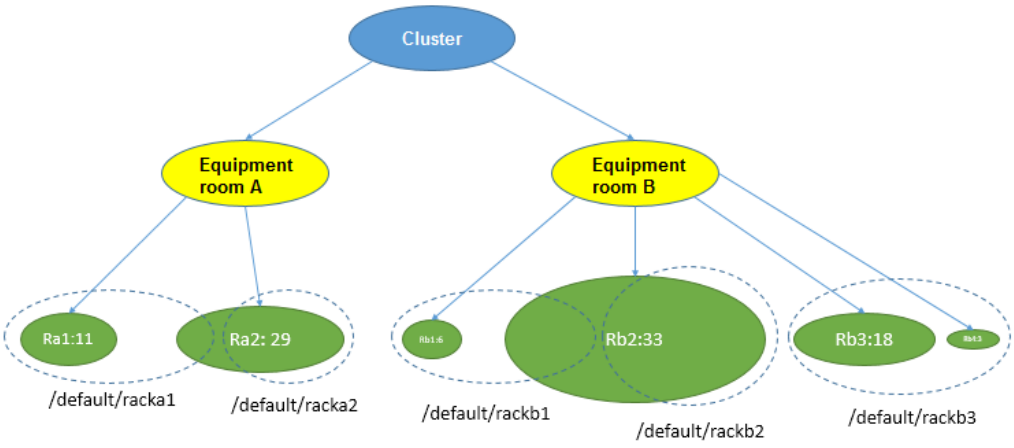
For example, in a cluster, 100 hosts are located in two equipment rooms A and B. A has 40 hosts and B has 60 hosts. In room A, there are 11 hosts on physical rack Ra1 and 29 hosts on physical rack Ra2. In room B, there are six hosts on physical rack Rb1, 33 hosts on physical rack Rb2, 18 hosts on physical rack Rb3, and three hosts on physical rack Rb4.

According to the rack allocation policy, each logical rack contains nearly the same number (for example, 20) of hosts. The allocation details are as follows:

- Logical rack /default/racka1: 11 hosts on physical rack Ra1 and nine hosts on physical rack Ra2
- Logical rack /default/racka2: the remaining 20 hosts (except the nine hosts of logical rack /default/racka1) on physical rack Ra2
- Logical rack /default/rackb1: six hosts on physical rack Rb1 and 13 hosts on physical rack Rb2
- Logical rack /default/rackb2: the remaining 20 hosts on physical rack Rb2

- Logical rack /default/rackb3: 18 hosts on physical rack Rb3 and three hosts on physical rack Rb4

Rack allocation example:



Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Click **Hosts**.

Step 3 Select the check box of the target host.

Step 4 Select **Set Rack** from the **More** drop-down list.

- Set rack names in hierarchy based on the actual network topology. Separate racks from different layers using slashes (/).
- Rack naming rules are as follows: */level1/level2/...* The number of levels must be at least 1, and the name cannot be empty. A rack can contain letters, digits, and underscores (_) and cannot exceed 200 characters.

  For example, /default/rack0.
- If the hosts in the rack to be modified contain DataNode instances, ensure that the rack name levels of the hosts where all DataNode instances reside are the same. Otherwise, the configuration fails to be delivered.

Step 5 Click **OK**.

----End

10.4.2.4 Isolating a Host

Scenario

If a host is abnormal or faulty and cannot provide services or affects the cluster performance, you can remove the host from the available node in the cluster temporarily so that the client can access other available nodes.

NOTE

Only non-management nodes can be isolated.

Impact on the System

- After a host is isolated, all role instances on the host will be stopped, and you cannot start, stop, or configure the host and all instances on the host.
- For some services, after a host is isolated, some instances on other nodes do not work, and the service configuration status may expire.
- After a host is isolated, statistics about the monitoring status and indicator data of the host hardware and instances on the host cannot be collected or displayed.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Click **Hosts**.

Step 3 Select the check box of the host to be isolated.

Step 4 Select **Isolate** from the **More** drop-down list.

In the displayed dialog box, enter the password of the current login user and click **OK**.

Step 5 In the displayed confirmation dialog box, select "I confirm to isolate the selected hosts and accept possible consequences of service faults." Click **OK**.

Wait until the message "Operation succeeded" is displayed, and click **Finish**.

The host is successfully isolated and **Running Status** is **Isolated**.

Step 6 Log in to the isolated host as user **root** and run the **pkill -9 -u omm** command to stop the processes of user **omm** on the node. Then run the **ps -ef | grep 'container' | grep '${BIGDATA_HOME}' | awk '{print $2}' | xargs -I '{}' kill -9 '{}'** command to find and stop the container process.

Step 7 Cancel the isolation status of the host before using the host if you have rectified the host exception or fault.

On the **Hosts** page, select the isolated host and choose **More** > **Cancel Isolation**.

NOTE

After the isolation is canceled, all role instances on the host are not started by default. To start role instances on the host, select the target host on the Hosts page and choose **More** > **Start All Instances**.

----End

10.4.2.5 Exporting Host Information

Scenario

Administrators can export information about all hosts on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Click **Hosts**.

Step 3 Specify the status of required hosts in the drop-down list box on the upper right corner, or click **Advanced Search** to specify hosts.

Step 4 Click **Export All**, select **TXT** or **CSV** for **Save As**, and click **OK**.

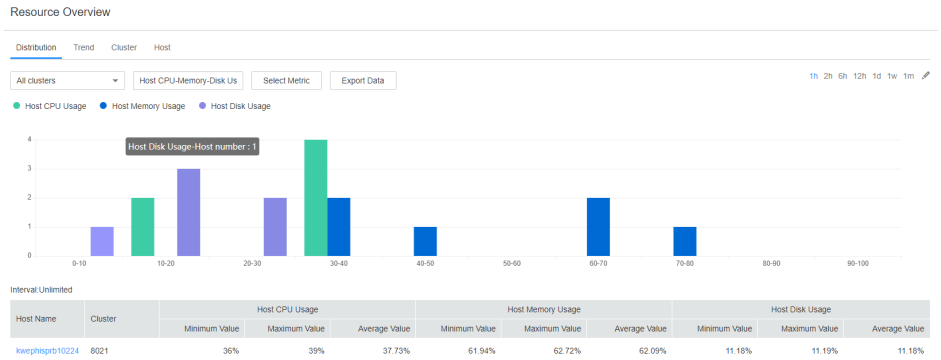
----End

10.4.3 Resource Overview

10.4.3.1 Distribution

Log in to FusionInsight Manager and choose **Hosts** > **Resource Overview**. On the **Resource Overview** page that is displayed, click the **Distribution** tab to view resource distribution of each cluster. By default, the monitoring data of the past one hour (**1h**) is displayed. You can click to customize a time range. Time range options are **1h**, **2h**, **6h**, **12h**, **1d**, **1w**, and **1m**.

Figure 10-6 Distribution tab



- You can click **Select Metric** to customize the metric to monitor. **Table 10-17** describes all the metrics that you can select. After you select a metric, the host distribution in each range of the metric is displayed.
- When you hover your cursor over a color column, the number of hosts in the current metric range is displayed. See **Figure 10-6**. You can click a color column to view the list of hosts in the metric range.
  - You can click a host name in the **Host Name** column to access the host details page.
  - You can click **View Trends** in the **Operation** column of a host to view the maximum, minimum, and average values of the current metric in the cluster as well as the value of the current host. In the current cluster, if you have selected **Host CPU-Memory-Disk Usage**, **View Trends** is unavailable.
- You can click **Export Data** to export the maximum, minimum, and average values of the current metric of all nodes in the cluster within the time range you have specified.

Table 10-17 Metrics

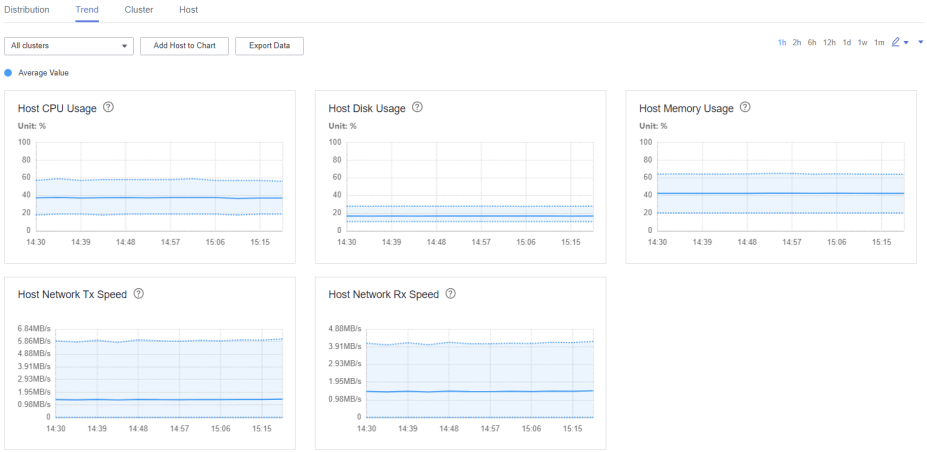
Category	Metric
Process	• Number of Running Processes • Total Number of Processes • Total Number of omm Processes • Uninterruptible Sleep Process
Network Status	• Host Network Packet Collisions • Number of LAST_ACK States • Number of CLOSING States • Number of LISTENING States • Number of CLOSED States • Number of ESTABLISHED States • Number of SYN_RECV States • Number of TIME_WAITING States • Number of FIN_WAIT2 States • Number of FIN_WAIT1 States • Number of CLOSE_WAIT States • DNS Name Resolution Duration • TCP Ephemeral Port Usage • Host Network Packet Frame Errors
Network Reading	• Host Network Read Packets • Host Network Read Dropped Packets • Host Network Read Error Packets • Host Network Rx Speed
Disk	• Host Disk Write Speed • Host Used Disk • Host Free Disk • Host Disk Read Speed • Host Disk Usage
Memory	• Free Memory • Cache Memory Size • Total Kernel Cache Memory Size • Shared Memory Size • Host Memory Usage • Used Memory

Category	Metric
Network Writing	• Host Network Write Packets • Host Network Write Error Packets • Host Network Tx Speed • Host Network Write Dropped Packets
CPU	• CPU Usage of Processes Whose Priorities Have Been Changed • CPU Usage of User Space Processes • CPU Usage of Kernel Space Processes • Host CPU Usage • CPU Total Time • CPU Idle Time
Host Status	• Host File Handle Usage • Average OS Load in 1 Minute • Average OS Load in 5 Minutes • Average OS Load in 15 Minutes • Host PID Usage

10.4.3.2 Trend

Log in to FusionInsight Manager and choose **Hosts** > **Resource Overview**. Click **Trend** to view resource trends of the cluster. By default, the monitoring data of the past one hour (**1h**) is displayed. You can click to customize a time range. Time range options are **1h**, **2h**, **6h**, **12h**, **1d**, **1w**, and **1m**. By default, the trend chart of each metric displays the maximum, minimum, and average values of the entire cluster.

Figure 10-7 Trend tab



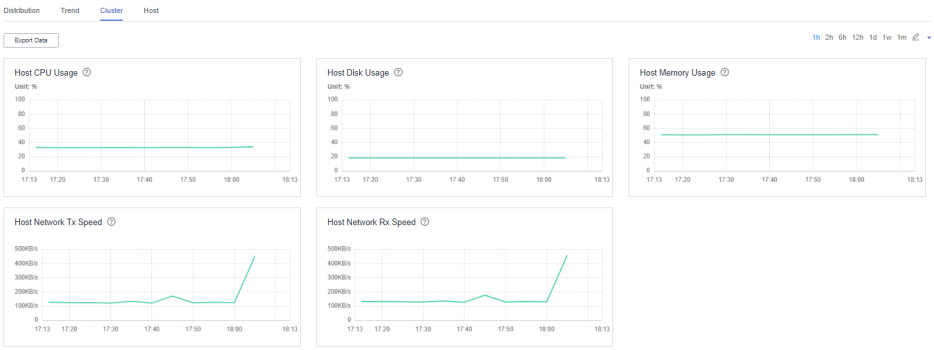
- You can click **Add Host to Chart** to add trend lines of up to 12 hosts to the trend charts.
- You can choose ▼ > **Customize** to customize the metrics to display on the tab page. For details about the metrics, see **Table 10-17** in **Distribution**.
- You can click **Export Data** to export the maximum, minimum, and average values of all nodes in the cluster for all selected metrics within the time range you have specified.

10.4.3.3 Cluster

Log in to FusionInsight Manager and choose **Hosts** > **Resource Overview**. On the **Resource Overview** page that is displayed, click the **Cluster** tab to view resource monitoring of all clusters.

By default, the monitoring data of the past one hour (**1h**) is displayed. You can click ✎ to customize a time range. Time range options are **1h**, **2h**, **6h**, **12h**, **1d**, **1w**, and **1m**.

Figure 10-8 Cluster tab



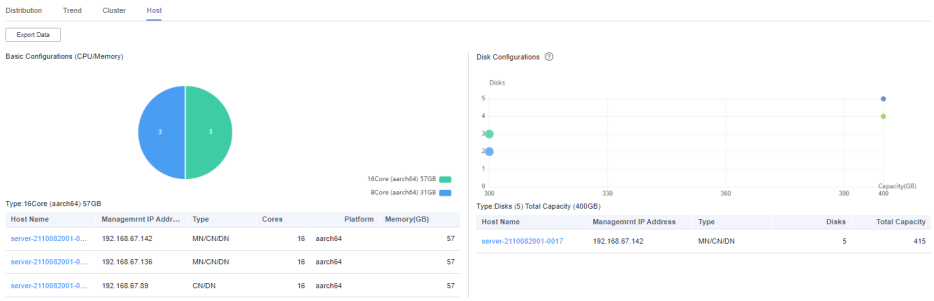
- You can choose ▼ > **Customize** to customize the metrics to display on the tab page. For details about the metrics, see **Table 10-17** in **Distribution**.
- You can click **Export Data** to export the metric values of the cluster within the time range you have specified.

10.4.3.4 Host

Log in to FusionInsight Manager and choose **Hosts** > **Resource Overview**. On the **Resource Overview** page that is displayed, click the **Host** tab to view host resource overview, including basic configurations (CPU/memory) and disk configurations.

You can click **Export Data** to export the configuration list of all hosts in the cluster, including the host name, management IP address, host type, number of cores, CPU architecture, memory capacity, and disk size.

Figure 10-9 Host tab



Basic Configurations (CPU/Memory)

You can hover your cursor over the pie chart to view the number of hosts of each hardware configuration in the cluster. The information is displayed in the format of *Number of cores (CPU architecture) Memory size*.

You can click a slice on the pie chart to view the list of hosts.

Disk Configurations

The horizontal axis indicates the total disk capacity (including the OS disk) of a node, and the vertical axis indicates the number of logical disks (including the OS disk).

You can hover your cursor over a dot to view information about disks of the current configuration, including the quantity of disks, total capacity, and number of hosts.

You can click a dot on the chart to view the list of hosts.

10.5 O&M

10.5.1 Alarms

10.5.1.1 Overview of Alarms and Events

Alarms

Log in to FusionInsight Manager and choose **O&M** > **Alarm** > **Alarms**. You can view information about alarms reported by all clusters, including the alarm name, ID, severity, and generation time. By default, the latest 10 alarms are displayed on each page.

You can click ⌄ on the left of an alarm to view detailed alarm parameters. **Table 10-18** describes the parameters.

Table 10-18 Alarm parameters

Parameter	Description
Alarm ID	Alarm ID
Alarm Name	Alarm name
Severity	Alarm severity. Value options are **Critical**, **Major**, **Minor**, and **Suggestion**.
Generated	Time when an alarm is generated
Cleared	Time when an alarm is cleared. If the alarm is not cleared, **--** is displayed.
Source	Cluster name
Object	Service, process, or module that triggers the alarm
Automatically Cleared	Whether the alarm can be automatically cleared after the fault is rectified
Alarm Status	Current status of the alarm. Value options are **Auto**, **Manual**, and **Uncleared**.
Alarm Cause	Indicates the possible cause of an alarm.
Serial Number	Indicates the number of alarms generated by the system.
Additional Information	Indicates the error information. You can view the monitoring metric values in **Additional Information** if thresholds are set for the metrics to generate alarms.
Location	Detailed information for locating the alarm, which includes the following: ● **Source**: cluster for which the alarm is generated ● **ServiceName**: service for which the alarm is generated ● **RoleName**: role for which the alarm is generated ● **HostName**: host for which the alarm is generated

Manage alarms.

- Click **Export All** to export all alarm details.
- If multiple alarms have been handled, you can select one or more alarms to be cleared and click **Clear Alarm** to clear the alarms in batches. A maximum of 300 alarms can be cleared in each batch.
- You can click to manually refresh the current page and click to filter columns to display.

- You can filter alarms by object or severity.
- You can click **Advanced Search** to search for alarms by alarm ID, name, type, start time, or end time. Click **Search** to filter alarms that meet the search criteria. Click **Advanced Search** again to view the number of search criteria that you have configured.
- You can click **Clear**, **Mask**, or **View Help** to perform corresponding operations on an alarm.
- If there are a large number of alarms, you can click **View by Category** to sort uncleared alarms by alarm ID. After alarms are classified, click the number of uncleared alarms to view alarm details.

Events

Log in to FusionInsight Manager and choose **O&M** > **Alarm** > **Events**. On the **Events** page that is displayed, you can view information about all events in the cluster, including the event name, ID, severity, generation time, object, and location. By default, the latest 10 events are displayed on each page.

You can click ⌄ on the left of an event to view detailed event parameters. **Table 10-19** describes the parameters.

Table 10-19 Event parameters

Parameter	Description
Event ID	Event ID
Event Name	Event name
Severity	Event severity. Value options are **Critical**, **Major**, **Minor**, and **Suggestion**.
Generated	Time when an event is generated
Object	Object for which the event may be generated
Serial Number	Number of the event generated by the system
Location	Detailed information for locating the event, which includes the following: • **Source**: cluster for which the event is generated • **ServiceName**: service for which the event is generated • **RoleName**: role for which the event is generated • **HostName**: host for which the event is generated
Additional Information	Indicates the error information.
Event Cause	Indicates the possible cause of an event.
Source	Cluster name

Manage events.

- Click **Export All** to export all event details.
- You can click to manually refresh the current page and click to filter columns to display.
- You can filter events by object or cluster.
- You can click **Advanced Search** to search for events by event ID, name, severity, start time, or end time.

10.5.1.2 Configuring Alarm Threshold

Scenario

You can configure monitoring indicator thresholds to monitor the health status of indicators on FusionInsight Manager. If abnormal data occurs and the preset conditions are met, the system triggers an alarm and displays the alarm information on the alarm page.

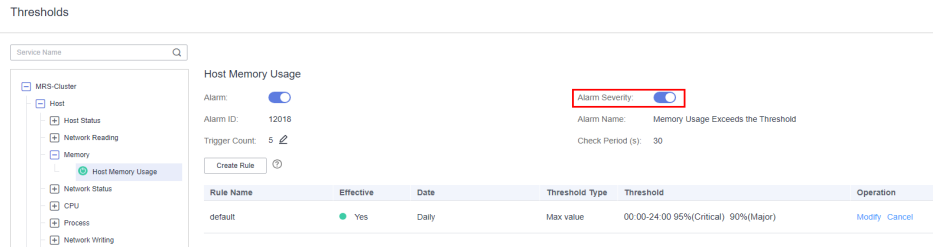
Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **O&M** > **Alarm** > **Thresholds**.

Step 3 Select a monitoring metric for a host or service in the cluster.

Figure 10-10 Configuring the threshold for a metric



For example, after selecting **Host Memory Usage**, the information about this indicator threshold is displayed.

- When **Switch** is on, an alarm will be triggered if the threshold is met.
- When **Alarm Severity** is on, hierarchical alarms are enabled. The system dynamically reports alarms of the corresponding severity based on the real-time metric values and hierarchical thresholds set for that severity.
- **Alarm ID** and **Alarm Name**: alarm information triggered against the threshold
- **Trigger Count**: FusionInsight Manager checks whether the value of a monitoring metric reaches the threshold. If the number of consecutive checks reaches the value of **Trigger Count**, an alarm is generated. **Trigger Count** is configurable.
- **Check Period (s)**: interval for the system to check the monitoring metric.
- The rules in the rule list are used to trigger alarms.

Step 4 Click **Create Rule** to add rules used for monitoring indicators.

Table 10-20 Monitoring indicator rule parameters

Parameter	Description	Example Value
Rule Name	Set a rule name.	CPU_MAX
Severity	Select an alarm severity. After **Alarm Severity** is on, you need to configure the alarm severity in **Thresholds**.	• Critical • Major • Minor • Warning
Threshold Type	You can use the maximum or minimum value of an indicator as the alarm triggering threshold. If **Threshold Type** is set to **Max value**, the system generates an alarm when the value of the specified indicator is greater than the threshold. If **Threshold Type** is set to **Min value**, the system generates an alarm when the value of the specified indicator is less than the threshold.	• Max value • Min value
Date	This parameter is used to set the date when the rule takes effect. If **Alarm Severity** is on, only **Daily** is supported.	• Daily • Weekly • Others
Add Date	This parameter is available only when **Date** is set to **Others**. You can set the date when the rule takes effect. Multiple options are available.	09-30

Parameter	Description	Example Value
Thresholds	This parameter is used to set the time range when the rule takes effect. If **Alarm Severity** is on, you cannot set the start time and end time. The default start time and end time are 00:00-23:59.	Start and End Time: 00:00–08:30
	Thresholds of the rule monitoring metric After **Alarm Severity** is on, different alarm severities can be set for a cluster based on different thresholds.	• Alarm severity • Threshold

NOTE

You can click to set multiple time ranges for the threshold or click to delete one.

Step 5 Click **OK** to save the rules.

Step 6 Locate the row that contains an added rule, and click **Apply** in the **Operation** column. The value of **Effective** for this rule changes to **Yes**.

A new rule can be applied only after you click **Cancel** for an existing rule.

----End

Monitoring Metric Reference

FusionInsight Manager alarm monitoring metrics are classified as node information metrics and cluster service metrics. **Table 10-21** describes the metrics for which you can configure thresholds on nodes.

Table 10-21 Node monitoring metrics

Metric Group	Metric	Description	Default Threshold
CPU	Host CPU Usage	This indicator reflects the computing and control capabilities of the current cluster in a measurement period. By observing the indicator value, you can better understand the overall resource usage of the cluster.	90.0%
Disk	Disk Usage	Indicates the disk usage of a host.	95% (critical) 85% (major)
	Disk Inode Usage	Indicates the disk inode usage in a measurement period.	95% (critical) 80% (major)
Memory	Host Memory Usage	Indicates the average memory usage at the current time.	95% (critical) 90% (major)
Host Status	Host File Handle Usage	Indicates the usage of file handles of the host in a measurement period.	95% (critical) 80% (major)
	Host PID Usage	Indicates the PID usage of a host.	95% (critical) 90% (major)
Network Status	TCP Ephemeral Port Usage	Indicates the usage of temporary TCP ports of the host in a measurement period.	95% (critical) 80% (major)

Metric Group	Metric	Description	Default Threshold
Network Reading	Read Packet Error Rate	Indicates the read packet error rate of the network interface on the host in a measurement period.	5% (critical) 0.5% (major)
	Read Packet Dropped Rate	Indicates the read packet dropped rate of the network interface on the host in a measurement period.	5% (critical) 0.5% (major)
	Read Throughput Rate	Indicates the average read throughput (at MAC layer) of the network interface in a measurement period.	80%
Network Writing	Write Packet Error Rate	Indicates the write packet error rate of the network interface on the host in a measurement period.	5% (critical) 0.5% (major)
	Write Packet Dropped Rate	Indicates the write packet dropped rate of the network interface on the host in a measurement period.	5% (critical) 0.5% (major)
	Write Throughput Rate	Indicates the average write throughput (at MAC layer) of the network interface in a measurement period.	80%

Metric Group	Metric	Description	Default Threshold
Process	Uninterruptible Sleep Process	Number of D state and Z state processes on the host in a measurement period	0
	omm Process Usage	omm process usage in a measurement period	95% (critical) 90% (major)

Table 10-22 Cluster service indicators

Service	Metric Group	Metric	Description	Default Threshold
DBService	Database	Usage of the Number of Database Connections	Indicates the usage of the number of database connections.	95% (critical) 90% (major)
		Disk Space Usage of the Data Directory	Disk space usage of the data directory	85% (critical) 80% (major)
MOTService	Database	MOT Connections Usage	Usage of MOTService database connections	90%
		MOT Disk Space Usage of the Data Directory	Disk space usage of the MOTService data directory	80%
		MOT Used Memory Percentage	MOTService memory usage	85%
		MOT Used CPU Percentage	MOTService CPU usage	80%
Elasticsearch	Disk	Data Directory Usage	Elasticsearch data directory usage	80%

Service	Metric Group	Metric	Description	Default Threshold
	Garbage Collection	GC Time	Garbage collection duration of the Elasticsearch instance process	30000ms
	Memory	Heap Memory Usage	Elasticsearch heap memory usage	90%
	Shard	Elasticsearch Shard Document Number	Number of Elasticsearch sharded files	100000000
		Elasticsearch Shard Data Volume	Size of Elasticsearch shards	41943040
		Number of Instance Shards	Total number of Elasticsearch instance shards	400
	Replica Quantity Statistics	Total shard number	Number of primary shards whose Elasticsearch status is down	70000
Flume	Agent	Flume Heap Memory Usage Calculate	Indicates the Flume heap memory usage.	95.0% (critical) 90.0% (major)
		Flume Direct Memory Usage Statistics	Indicates the Flume direct memory usage.	90.0% (critical) 80.0% (major)
		Flume Non-heap Memory Usage	Indicates the Flume non-heap memory usage.	80.0%
		Total GC duration of Flume process	Indicates the Flume total GC time.	12000 ms

Service	Metric Group	Metric	Description	Default Threshold
FTP-Server	Process	FTP-Server Heap Memory Usage Calculate	Indicates the FTP-Server heap memory usage.	95.0%
		FTP-Server Direct Buffer Usage Statistics	Indicates the FTP-Server direct memory usage.	80.0%
		FTP-Server Non-Heap Memory Usage	Indicates the FTP-Server non-heap memory usage.	80.0%
		Total GC duration of FTP-Server process	Indicates the total GC time of FTP-Server.	12000 ms
HBase	GC	GC time for old generation	Total GC time of RegionServer	5000 ms
		GC time for old generation	Total GC time of HMaster	5000 ms
	CPU & memory	RegionServer Direct Memory Usage Statistics	RegionServer direct memory usage	90%
		RegionServer Heap Memory Usage Statistics	RegionServer heap memory usage	90%
		HMaster Direct Memory Usage	HMaster direct memory usage	90%
		HMaster Heap Memory Usage Statistics	HMaster heap memory usage	90%

Service	Metric Group	Metric	Description	Default Threshold
	Service	Number of Online Regions of a RegionServer	Number of regions of a RegionServer	5000 (critical) 2000 (major)
		Region in transaction count over threshold	Number of regions that are in the RIT state and reach the threshold duration	1
	Handler	RegionServer Handler Usage	Handler usage of RegionServer	100% (critical) 90% (major)
	Replication	Replication sync failed times (RegionServer)	Number of times that DR data fails to be synchronized	1
		Number of Log Files to Be Synchronized in the Active Cluster	Number of log files to be synchronized in the active cluster	128
		Number of HFiles to Be Synchronized in the Active Cluster	Number of HFiles to be synchronized in the active cluster	128
	RPC	Number of RegionServer Opened Connections	Number of open RegionServer RPC connections	200 (critical) 100 (major)
		99th Percentile of the RegionServer RPC Request Response Time	99th percentile of the RegionServer RPC request response time	10000 ms (critical) 5000 ms (major)

Service	Metric Group	Metric	Description	Default Threshold
		99th Percentile of the RegionServer RPC Request Processing Time	99th percentile of the RegionServer RPC request processing time	10000 ms (critical) 5000 ms (major)
	Operation statistics	Number of Timed-Out WAL Writes in RegionServers	Number of timed-out WAL writes in RegionServers	500 (critical) 300 (major)
	Queue	Number of Tasks in RegionServer RPC Write Queues	Number of tasks in RegionServer RPC write queues	2000 (critical) 1600 (major)
		Number of Tasks in RegionServer RPC Read Queues	Number of tasks in RegionServer RPC read queues	2000 (critical) 1600 (major)
		RegionServer Call Queue Size	RegionServer call queue size	838860800 (critical) 629145600 (major)
		Compaction Queue Size	Size of the Compaction queue	100
HDFS	File and Block	Lost Blocks	Number of backup blocks that the HDFS file system lacks	0
		Blocks Under Replicated	Total number of blocks that need to be replicated by the NameNode	1000

Service	Metric Group	Metric	Description	Default Threshold
	RPC	Average Time of Active NameNode RPC Processing	Average NameNode RPC processing time	100 ms (major) 200 ms (critical)
		Average Time of Active NameNode RPC Queuing	Average NameNode RPC queuing time	200 ms (major) 300 ms (critical)
	Disk	HDFS Disk Usage	HDFS disk usage	80% (major) 90% (critical)
		DataNode Disk Usage	Disk usage of DataNodes in the HDFS	80%
		Percentage of Reserved Space for Replicas of Unused Space	Percentage of the reserved disk space of all the copies to the total unused disk space of DataNodes	90%
	Resource	Faulty DataNodes	Number of faulty DataNodes	3
		NameNode Non-Heap Memory Usage Statistics	Percentage of NameNode non-heap memory usage	90%
		NameNode Direct Memory Usage Statistics	Percentage of direct memory used by NameNodes	90%
		NameNode Heap Memory Usage Statistics	Percentage of NameNode non-heap memory usage	95%

Service	Metric Group	Metric	Description	Default Threshold
		DataNode Direct Memory Usage Statistics	Percentage of direct memory used by DataNodes	90%
		DataNode Heap Memory Usage Statistics	DataNode heap memory usage	95%
		DataNode Heap Memory Usage Statistics	Percentage of DataNode non-heap memory usage	90%
	Garbage Collection	GC Time (NameNode)/ GC Time (DataNode)	Garbage collection (GC) duration of NameNodes per minute	10000 ms (major) 15000 ms (critical)
		GC Time	GC duration of DataNodes per minute	12000 ms (major) 20000 ms (critical)
Hive	HQL	Percentage of HQL Statements That Are Executed Successfully by Hive	Percentage of HQL statements that are executed successfully by Hive	90% (critical) 80% (major)
	Connections	Percentage of Number of Sessions Connected to the MetaStore to the Maximum Allowed (MetaStore)	Percentage of the number of sessions connected to MetaStore to the maximum number of sessions allowed by MetaStore	90% (critical) 80% (major)
	Background	Background Thread Usage	Background thread usage	90% (critical) 80% (major)

Service	Metric Group	Metric	Description	Default Threshold
	GC	Total GC time of MetaStore	Total GC time of MetaStore	12000 ms
		HiveServer Total GC Time in Milliseconds	Total GC time of HiveServer	12000 ms
	Capacity	Percentage of HDFS Space Used by Hive to the Available Space	Percentage of HDFS space used by Hive to the available space	95% (critical) 85% (major)
	CPU & memory	MetaStore Direct Memory Usage Statistics	MetaStore direct memory usage	95% (critical) 85% (major)
		MetaStore Non-Heap Memory Usage Statistics	MetaStore non-heap memory usage	95% (critical) 85% (major)
		MetaStore Heap Memory Usage Statistics	MetaStore heap memory usage	95% (critical) 85% (major)
		HiveServer Direct Memory Usage Statistics	HiveServer direct memory usage	95% (critical) 85% (major)
		HiveServer Non-Heap Memory Usage Statistics	HiveServer non-heap memory usage	95% (critical) 85% (major)
		HiveServer Heap Memory Usage Statistics	HiveServer heap memory usage	95% (critical) 85% (major)

Service	Metric Group	Metric	Description	Default Threshold
	Session	Percentage of Sessions Connected to the HiveServer to Maximum Number of Sessions Allowed by the HiveServer	Indicates the percentage of the number of sessions connected to the HiveServer to the maximum number of sessions allowed by the HiveServer.	90% (critical) 80% (major)
Kafka	Partition	Percentage of Partitions That Are Not Completely Synchronized	Indicates the percentage of partitions that are not completely synchronized to total partitions.	60% (critical) 50% (major)
	Disk	Broker Disk Usage	Indicates the disk usage of the disk where the Broker data directory is located.	90% (critical) 85% (major)
		Disk I/O Rate of a Broker	I/O usage of the disk where the Broker data directory is located	80%
	Process	Broker GC Duration per Minute	Indicates the GC duration of the Broker process per minute.	12000 ms
		Heap Memory Usage of Kafka	Indicates the Kafka heap memory usage.	95%
		Kafka Direct Memory Usage	Indicates the Kafka direct memory usage.	100% (critical) 95% (major)

Service	Metric Group	Metric	Description	Default Threshold
	Others	User Connection Usage on Broker	Usage of user connections on Broker	90% (critical) 85% (major)
Loader	Memory	Heap Memory Usage Calculate	Indicates the Loader heap memory usage.	95% (critical) 80% (major)
		Direct Memory Usage of Loader	Indicates the Loader direct memory usage.	95% (critical) 80% (major)
		Non-heap Memory Usage of Loader	Indicates the Loader non-heap memory usage.	95% (critical) 80% (major)
	GC	Total GC time of Loader	Indicates the total GC time of Loader.	20000 ms (critical) 12000 ms (major)
MapReduce	Garbage Collection	GC Time	Indicates the GC time.	20000 ms (critical) 12000 ms (major)
	Resource	JobHistoryServer Direct Memory Usage Statistics	Indicates the JobHistoryServer direct memory usage.	95% (critical) 90% (major)
		JobHistoryServer Non-Heap Memory Usage Statistics	Indicates the JobHistoryServer non-heap memory usage.	95% (critical) 90% (major)
		JobHistoryServer Heap Memory Usage Statistics	Indicates the JobHistoryServer non-heap memory usage.	95% (critical) 90% (major)

Service	Metric Group	Metric	Description	Default Threshold
Metadata	Others	Heap Memory Usage Calculate	Indicates the Metadata heap memory usage.	95%
		Metadata Direct Memory Usage Statistics	Indicates the metadata direct memory usage.	80.0%
		Metadata Non-heap Memory Usage	Indicates the metadata non-heap memory usage.	80.0%
		Total GC time of Metadata	Indicates the metadata total GC time.	20000 ms (critical) 12000 ms (major)
Oozie	Memory	Oozie Heap Memory Usage Calculate	Indicates the Oozie heap memory usage.	95%
		Oozie Direct Memory Usage	Indicates the Oozie direct memory usage.	90%
		Oozie Non-heap Memory Usage	Indicates the Oozie non-heap memory usage.	90%
	GC	Total GC duration of Oozie	Indicates the Oozie total GC time.	20000 ms (critical) 12000 ms (major)
Solr	Replica Quantity Statistics	Bad Replica Number	Number of bad replicas of a Solr instance	0
	Garbage Collection	GC Time	Garbage collection duration of the Solr instance process	12000 ms

Service	Metric Group	Metric	Description	Default Threshold
	Memory	Heap Memory Usage	Indicates the heap memory usage.	99% (critical) 95% (major)
	Shard	Solr Shard Data Volume	Data volume of Solr shards	83886080 (critical) 41943040 (Major)
		Solr Shard Document Number	Number of Solr shard documents	400000000
Spark	Memory	JDBCServer Heap Memory Usage Statistics	JDBCServer heap memory usage	95% (critical) 85% (major)
		JDBCServer Direct Memory Usage Statistics	JDBCServer direct memory usage	95% (critical) 85% (major)
		JDBCServer Non-Heap Memory Usage Statistics	JDBCServer non-heap memory usage	95% (critical) 85% (major)
		JobHistory Direct Memory Usage Statistics	JobHistory direct memory usage	95% (major) 85% (minor)
		JobHistory Non-Heap Memory Usage Statistics	JobHistory non-heap memory usage	95% (major) 85% (minor)
		JobHistory Heap Memory Usage Statistics	JobHistory heap memory usage	95% (major) 85% (minor)

Service	Metric Group	Metric	Description	Default Threshold
		IndexServer Direct Memory Usage Statistics	IndexServer direct memory usage	95% (critical) 85% (major)
		IndexServer Heap Memory Usage Statistics	IndexServer heap memory usage	95% (critical) 85% (major)
		IndexServer Non-Heap Memory Usage Statistics	IndexServer non-heap memory usage	95% (critical) 85% (major)
	GC Count	Full GC Number of JDBCServer	Full GC times of JDBCServer	12 (critical) 9 (major)
		Full GC Number of JobHistory	Full GC times of JobHistory	12 (critical) 9 (major)
		Full GC Number of IndexServer	Full GC times of IndexServer	12 (critical) 9 (major)
	GC Time	JDBCServer Total GC Time in Milliseconds	Total GC time of JDBCServer	12000 ms (critical) 9600 ms (major)
		JobHistory Total GC Time in Milliseconds	Total GC time of JobHistory	12000 ms (major) 9600 ms (minor)
		IndexServer Total GC Time in Milliseconds	Total GC time of IndexServer	12000 ms (critical) 9600 ms (major)
Yarn	Resources	NodeManager Direct Memory Usage Statistics	Indicates the percentage of direct memory used by NodeManagers.	90%

Service	Metric Group	Metric	Description	Default Threshold
		NodeManager Heap Memory Usage Statistics	Indicates the percentage of NodeManager heap memory usage.	95%
		NodeManager Non-Heap Memory Usage Statistics	Indicates the percentage of NodeManager non-heap memory usage.	90%
		ResourceManager Direct Memory Usage Statistics	Indicates the ResourceManager direct memory usage.	90%
		ResourceManager Heap Memory Usage Statistics	Indicates the ResourceManager heap memory usage.	95%
		ResourceManager Non-Heap Memory Usage Statistics	Indicates the ResourceManager non-heap memory usage.	90%
	Garbage collection	GC Time	Indicates the GC duration of NodeManager per minute.	12000 ms (major) 20000 ms (critical)
		GC Time	Indicates the GC duration of ResourceManager per minute.	10000 ms (major) 15000 ms (critical)
	Others	Failed Applications of root queue	Number of failed tasks in the root queue	50
		Terminated Applications of root queue	Number of killed tasks in the root queue	50

Service	Metric Group	Metric	Description	Default Threshold
	CPU & memory	Pending Memory	Pending memory capacity	83886080MB
	Application	Pending Applications	Pending tasks	60
ZooKeeper	Connection	ZooKeeper Connections Usage	Indicates the percentage of the used connections to the total connections of ZooKeeper.	80% (major) 90% (critical)
	CPU & memory	ZooKeeper Heap Memory Usage	Indicates the ZooKeeper heap memory usage.	95%
		ZooKeeper Direct Memory Usage	Indicates the ZooKeeper direct memory usage.	80%
	GC	ZooKeeper GC Duration per Minute	Indicates the GC time of ZooKeeper every minute.	5000 ms (major) 10000 ms (critical)
meta	OBS data write operation	Total Number of Failed OBS Write API Calls	Total number of failed OBS write API calls	10
	OBS exception	Total Number of OBSFileConflictException Errors	Total number of OBSFileConflictException errors	5
		Total Number of OBS AccessControlExceptions Errors	Total number of OBS AccessControlExceptions errors	5
		Total Number of OBS EOFException Errors	Total number of OBS EOFException errors	5

		PolicySync Non-Heap Memory Usage	Percentage of PolicySync non-heap memory usage	80.0%
		RangerAdmin Non-Heap Memory Usage	RangerAdmin non-heap memory usage	80.0%

Service	Metric Group	Metric	Description	Default Threshold
		RangerAdmin Heap Memory Usage	RangerAdmin heap memory usage	95.0%
		RangerAdmin Direct Memory Usage	RangerAdmin direct memory usage	80.0%
		TagSync Direct Memory Usage	TagSync direct memory usage	80.0%
		TagSync Non-Heap Memory Usage	TagSync non-heap memory usage	80.0%
		TagSync Heap Memory Usage	TagSync heap memory usage	95.0%
ClickHouse	Cluster Quota	Clickhouse service quantity quota usage in ZooKeeper	Quota of the ZooKeeper nodes used by a ClickHouse service	95% (critical) 90% (major)
		Capacity quota usage of the Clickhouse service in ZooKeeper	Capacity quota of ZooKeeper directory used by the ClickHouse service	95% (critical) 90% (major)
	Concurrencies	Concurrency Number (ClickHouseServer)	Actual number of concurrent SQL statements of the ClickHouse service	90
IoTDB	Merge	Maximum Task Merge (Intra-Space Merge) Latency	Maximum latency of IoTDBServer intra-space merge	300000ms

Service	Metric Group	Metric	Description	Default Threshold
		Maximum Merge Task (Flush) Latency	Maximum latency of IoTDBServer flush execution	300000ms
		Maximum Task Merge (Cross-Space Merge) Latency	Maximum latency of IoTDBServer cross-space merge	300000ms
	RPC	Maximum RPC (executeStatement) Latency	Maximum latency of IoTDBServer RPC execution	10000s
	GC	Total GC duration of IoTDBServer	Total time used for IoTDBServer garbage collection (GC)	30000 ms (critical) 12000 ms (major)
		Total GC Duration of ConfigNode	Total time used for ConfigNode garbage collection (GC)	30000 ms (critical) 12000 ms (major)
	Memory	IoTDBServer Heap Memory Usage	IoTDBServer heap memory usage	100% (critical) 90% (major)
		IoTDBServer Direct Memory Usage	IoTDBServer direct memory usage	100% (critical) 90% (major)
		ConfigNode Heap Memory Usage	Percentage of the ConfigNode heap memory usage	100% (critical) 90% (major)
		ConfigNode Direct Memory Usage	Percentage of the ConfigNode direct memory usage	100% (critical) 90% (major)

Service	Metric Group	Metric	Description	Default Threshold
Containers	Others	Metaspace Usage	WebContainer metaspace usage	75.0%
		Non-Heap Memory Usage	WebContainer non-heap memory usage	75.0%
		Heap Memory Usage	WebContainer heap memory usage	95.0%
		Failure Rate of Application Service Calling	Failure rate of application service calling (SGP)	10.0
		Application Service Calling Latency	Application service calling latency (SGP)	10000.0
		Maximum Number of Concurrent Application Services	Maximum number of concurrent application services (SGP)	120
		BLU Health Status	BLU health status statistics	50.0%
LdapServer	Others	Process Connections of a Single SlapdServer Instance	Number of SlapdServer process connections	1000
		CPU Usage of a Single SlapdServer Instance	SlapdServer CPU usage	1200%
Guardian	GC	TokenServer GC Duration	TokenServer GC duration	12000 ms
	CPU & memory	TokenServer Heap Memory Usage	Percentage of the heap memory used by the TokenServer process	95.0%

Service	Metric Group	Metric	Description	Default Threshold
		TokenServer Non-Heap Memory Usage	Percentage of the non-heap memory used by the TokenServer process	80.0%
		TokenServer Direct Memory Usage	Percentage of the TokenServer direct memory usage	80.0%
Doris	JVM	Accumulated Old-Generation GC Duration	Accumulated GC duration of the old-generation FE process	3000ms
	Connection	FE Ratio of the number of MySQL port connections (FE)	Proportion of connections to the MySQL port of the FE node	95%
	Disk	BE Data Disk Usage	BE data disk usage	95%
		Disk Status of a Specified Data Directory	Statistics on abnormal disk status of a specified data directory on the BE.	1
	Performance	Maximum Compaction Score of All BE Nodes	Maximum FE compaction score of all BE nodes	10
		Maximum Duration of RPC Requests Received by Each Method of the FE Thrift Interface	Maximum duration of RPC requests received by each method of the FE thrift interface.	5000ms

Service	Metric Group	Metric	Description	Default Threshold
	Queue	Queue Length of BE Periodic Report Tasks on the FE	Queue length of BE periodic report tasks on the FE node	10
		Number of FE Tasks Queuing in the Thread Pool Interacting with the BE	Number of FE tasks queuing in the thread pool interacting with the BE node	10
		Number of FE Tasks Queuing in the Task Processing Thread Pool	Number of FE tasks that are queuing in the task processing thread pool on the FE node	10
		Queue Length of Query Execution Thread Pool	Queue length of query execution thread pool	20
	Exception	Failed Metadata Image Generation	Failed metadata image generation on the FE node	1
		Failed Historical Metadata Image Clearing	Failed historical metadata image clearing on the FE node	1
		Status of the Doris FE instance (FE)	Process status statistics of the Doris FE instance.	0
		Status of the Doris BE instance (BE)	Process status statistics of the Doris BE instance.	0

Service	Metric Group	Metric	Description	Default Threshold
		Error Rate of TCP Packet Receiving (BE)	Error rate of TCP packet receiving on the BE	5%
		Whether the Number of Task Failures of a Certain Type Increases (BE)	Whether the number of failures of a certain type of tasks executed on the BE increases	1
	CPU and Memory	FE CPU Usage	CPU usage statistics on FE nodes	95% (critical) 90% (major)
		FE Memory Usage	Memory usage statistics on FE nodes	90% (critical) 85% (major)
		FE Memory Usage	Memory usage of FE nodes	95%
		FE Heap Memory Usage Rate	Heap memory usage of FE nodes	95%
		BE Memory Usage Rate	Memory usage statistics on BE nodes	90% (critical) 85% (major)
		Maximum BE Memory and Remaining Machine Memory on the BE	The maximum memory required by the BE is greater than the remaining available memory.	1
		BE CPU Usage	CPU usage statistics on BE nodes	95% (critical) 90% (major)

10.5.1.3 Configuring the Alarm Masking Status

Scenario

If you do not want FusionInsight Manager to report specified alarms in the following scenarios, you can manually mask the alarms.

- Some unimportant alarms and minor alarms need to be masked.
- When a third-party product is integrated with MRS, some alarms of the product are duplicated with the alarms of MRS and need to be masked.
- When the deployment environment is special, certain alarms may be falsely reported and need to be masked.

After an alarm is masked, new alarms with the same ID as the alarm are neither displayed on the **Alarm** page nor counted. The reported alarms are still displayed.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **O&M** > **Alarm** > **Masking Setting**.

Step 3 In the **Masking Setting** area, select the specified service or module.

Step 4 Select an alarm from the alarm list.

Figure 10-11 Masking an alarm

The information about the alarm is displayed, including the alarm name, ID, severity, masking status, and operations can be performed on the alarm.

- The masking status includes **Display** and **Masking**.
- Operations include **Masking** and **Help**.

NOTE

You can filter specified alarms based on the masking status and alarm severity.

Step 5 Set the masking status for an alarm:

- Click **Masking**. In the displayed dialog box, click **OK** to change the alarm masking status to **Masking**.
- Click **Cancel Masking**. In the dialog box that is displayed, click **OK** to change the masking status of the alarm to **Display**.

----End

10.5.2 Log

10.5.2.1 Log Online Search

Scenario

FusionInsight Manager allows you to search for logs online and view the log content of components to locate faults.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **O&M** > **Log** > **Online Search**.

Step 3 Configure the parameters listed in **Table 10-23** to search for the logs you need. You can select a default log search duration (including **0.5h**, **1h**, **2h**, **6h**, **12h**, **1d**, **1w**, and **1m**), or click to customize **Start Data** and **End Data**.

Table 10-23 Log search parameters

Parameter	Description
Search Content	Keywords or regular expression to be searched for
Service	Service or module for which you want to query logs
File	Log files to be searched for when only one role is selected
Lowest Log Level	Lowest level of logs to be queried. After you select a level, the logs of this level and higher levels are displayed. The levels in ascending order are as follows: TRACE < DEBUG < INFO < WARN < ERROR < FATAL
Host Scope	• You can click ... to select hosts. • Enter the host name of the node for which you want to query logs or the IP address of the management plane. • Use commas (,) to separate IP addresses, for example, **192.168.10.10**,**192.168.10.11**. • Use hyphens (-) to indicate an IP address segment if the IP addresses are consecutive, for example, **192.168.10.[10-20]**. • Use hyphens (-) to indicate an IP address segment if the IP addresses are consecutive, and use commas (,) to separate IP address segments, for example, **192.168.10.[10-20,30-40]**. **NOTE** – If this parameter is not specified, all hosts are selected by default. – A maximum of 10 expressions can be entered at a time. – A maximum of 2,000 hosts can be matched for all entered expressions at a time.

Parameter	Description
Advanced Configurations	• **Max Quantity**: maximum number of logs that can be displayed at a time. If the number of queried logs exceeds the value of this parameter, the earliest logs will be ignored. If this parameter is not set, the maximum number of logs that can be displayed at a time is not limited. • **Timeout Duration**: log query timeout duration. This parameter is used to limit the maximum log query time on each node. When the query times out, the query is stopped and the logs that have been searched for are still displayed.

Step 4 Click **Search**. Table 10-24 describes the fields in search results.

Table 10-24 Parameters in search results

Parameter	Description
Time	Time when a line of log is generated
Host Name	Host name of the node where the log file recording the line of log is located
Location	Path of the log file recording the line of log Click the location information to go to the online log browsing page. By default, 100 lines of logs before and 100 lines after the line of log are displayed. You can click **Load More** on the top or bottom of the page to view more logs. Click **Download** to download the log file to the local PC.
Line No.	Line number of a line of log in the log file
Level	Level of the line of log
Log	Log content

NOTE

You can click **Stop** to forcibly stop the search. You can view the search results in the list.

Step 5 Click **Filter** to filter the logs to display on the page. Table 10-25 lists the fields that you can use to filter logs. After you configure these parameters, click **Filter** to search for logs meeting the search criteria. You can click **Reset** to clear the information that you have filled in.

Table 10-25 Parameters for filtering logs

Parameter	Description
Keywords	Keywords of the losg to be searched for
Host Name	Name of the host to be searched for
Location	Path of the log file to be searched for
Started	Start time for logs to be searched for
Completed	End time for logs to be searched for

----End

10.5.2.2 Log Download

Scenario

FusionInsight Manager allows you to batch export logs generated on all instances of each service.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **O&M** > **Log** > **Download**.

Step 3 Select a log download range:

1. **Service**: Click ... and select a service.
2. **Host**: Enter the IP address of the host where the service is deployed. You can also click ... to select the required host.
3. **Maximum Concurrency**: Set the maximum number of concurrent nodes for log collection as required.
4. Click in the upper right corner and configure **Start Time** and **End Time**.

Step 4 Click **Download**.

The downloaded log package contains the topology information of the start time and end time, helping you quickly find the log you need.

The topology file is named in the format of **topo_<***Topology structure change time***>.txt**. The file contains the node IP address, host name, and service instances that reside on the node. (OMS nodes are identified by **Manager:Manager**.)

Example:

```
192.168.204.124|suse-124|
DBService:DBServer;KrbClient:KerberosClient;LdapClient:SlapdClient;LdapServer:SlapdServer;Manager:Manag
er;meta:meta
```

----End

10.5.3 Perform a Health Check

10.5.3.1 Viewing a Health Check Task

Scenario

Administrators can view all health check tasks in the health check management center to check whether the cluster is affected after the modification.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **O&M** > **Health Check**.

By default, all saved health check reports are listed. The parameters for a health check report are as follows:

Table 10-26 Parametes for a health check report

Parameter	Description
Check Object	Object to be checked. You can expand the list to view its details.
Status	Check result status. Value options are **No problems found**, **Problems found**, and **Checking**.
Check Type	Entity on which the check is to be performed. Value options are **System**, **Cluster**, **Host**, **Service**, and **OMS**. If you select **Cluster**, all items are checked by default.
Start Mode	Whether the health check is automatically or manually performed
Started	Start time of the check
Completed	End time of the check
Operation	Operations you can perform. Value options are **Export Report** and **View Help**.

NOTE

- In the upper right corner of the check list, you can filter health checks by check type or status.
- If **Check Type** is **Cluster**, **View Help** is displayed in the **Check Object** drop-down list.
- During a health check, the system determines whether check objects are healthy based on their historical monitoring metric data.

----End

10.5.3.2 Managing Health Check Reports

Scenario

FusionInsight Manager allows you to download and delete health check reports.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **O&M** > **Health Check**.

Step 3 Locate the row containing the target health check report and click **Export Report** in the **Operation** to download the report.

----End

10.5.3.3 Modifying Health Check Configuration

Scenario

Administrators can enable automatic health check to reduce manual operation time. By default, the automatic health check checks the entire cluster.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **O&M** > **Health Check** > **Configuration**.

Periodic Health Check indicates whether to enable automatic health check. Selecting **Enable** to enable the automatic health check, and selecting **Disable** to disable the function.

Set the health check period to **Daily**, **Weekly**, or **Monthly** as required.

Step 3 Click **OK** to save the configurations.

----End

10.5.4 Configuring Backup and Backup Restoration

10.5.4.1 Creating a Backup Task

Scenario

You can create backup tasks on FusionInsight Manager. Executing backup tasks backs up related data.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **O&M** > **Backup and Restoration** > **Backup Management**. On the page that is displayed, click **Create**.

Step 3 Set **Backup Object** to **OMS** or the cluster whose data you want to back up.

Step 4 Enter a task name in the **Name** text box.

Step 5 Set **Mode** to **Periodic** or **Manual** as required.

Table 10-27 Backup types

Type	Parameter	Description
Periodic backup	Start Time	Indicates the time when a periodic backup task is started for the first time.
	Period	Task execution interval. Value options are **Hours** and **Days**.
	Backup Policy	The following policies can be selected: • Full backup at the first time and subsequent incremental backup • Full backup every time • Full backup once every n times
Manual backup	N/A	You need to manually execute the task to back up data.

Step 6 Set required parameters in the **Configuration** area.

- Metadata and service data can be backed up.
- For details about how to back up data of different components, see **Backup and Recovery Management**.

Step 7 Click **OK** to save the configurations.

Step 8 In the backup task list, you can view the created backup task.

Locate the row that contains the target backup task, choose **More** > **Back Up Now** in the **Operation** column to execute the task immediately.

----End

10.5.4.2 Creating a Backup Restoration Task

Scenario

You can create a backup restoration task on FusionInsight Manager. After the restoration task is executed, the specified backup data is restored to the cluster.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **O&M** > **Backup and Restoration** > **Restoration Management**. On the page that is displayed, click **Create**.

Step 3 Configure **Task Name**.

Step 4 Set **Recovery Object** to **OMS** or the cluster whose data you want to restore.

Step 5 Set the required parameters in the **Recovery Configuration** area.

- Metadata and service data can be restored.
- For details about how to restore data of different components, see **Backup and Recovery Management**.

Step 6 Click **OK** to save the configurations.

Step 7 In the restoration task list, you can view the created restoration tasks.

Locate the row containing the target restoration task, click **Start** in the **Operation** column to execute the restoration task immediately.

----End

10.5.4.3 Managing Backup and Backup Restoration Tasks

Scenario

You can also maintain and manage backup restoration tasks on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **O&M** > **Backup and Restoration** > **Backup Management** or **Restoration Management**.

Step 3 In the **Operation** column of the specified task in the task list, select the operation to be performed.

Table 10-28 Maintenance and management operations

Operation Entry	Description
Config	Modify parameters for the backup task.

Operation Entry	Description
Recover	After some service data is successfully backed up, you can use this function to quickly restore data.
More > **Back Up Now**	Perform this operation to execute the backup task immediately.
More > **Stop**	Perform this operation to stop a running task.
More > **Delete** or **Delete**	This operation is used to delete tasks.
More > **Suspend**	Perform this operation to disable the automatic backup task function.
More > **Resume**	Perform this operation to enable the automatic backup task function.
More > **View History** or **View History**	Perform this operation to switch to the task run log page to view the task running details and backup path.
View	Perform this operation to check the parameter settings of the restoration task.
Start	Perform this operation to run the restoration task.

----End

10.6 Audit

10.6.1 Overview

Scenario

The **Audit** page displays the user operations on Manager. On this page, administrators can view historical user operations on Manager. For details about the audit information, see **Audit Logs**.

Overview

Log in to FusionInsight Manager and choose **Audit**. The **Audit** page displays the audit information, including the operation type, risk level, start time, end time, user, host name, service, instance, and operation result.

- You can select audit logs at the **Critical**, **Major**, **Minor**, or **Notice** level from the **All risk levels** drop-down list.
- In **Advanced Search**, you can set filter criteria to query audit logs.
  a. You can query audit logs by user management, cluster, service, and health in the **Operation Type** column.
  b. In the **Service** column, you can select a service to query corresponding audit logs.

NOTE

You can select -- to search for audit logs using all other search criteria except services.

c. You can query audit logs by operation result. Value options are **All**, **Successful**, **Failed**, and **Unknown**.

- You can click to manually refresh the current page or click to filter the columns displayed in the page.
- Click **Export All** to export all audit information at a time. The audit information can be exported in **TXT** or **CSV** format.

10.6.2 Configuring Audit Log Dumping

Scenario

The audit logs of FusionInsight Manager are stored in the database by default. If the audit logs are retained for a long time, the disk space of the data directory may be insufficient. To store audit logs to another archive server, administrators can set the required dump parameters to automatically dump these logs. This facilitates the management of audit logs.

If you do not configure the audit log dumping, the system automatically saves the audit logs to a file when the number of audit logs reaches 100,000 pieces. The save path is **${BIGDATA_DATA_HOME} /dbdata_om/dumpData/iam/operatelog** on the active management node. The file name format is **OperateLog_store**_*YY_MM_DD_HH_MM_SS*.**csv**. The maximum number of historical audit log files is 50.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Audit** > **Configuration**.

Step 3 Click the switch on the right of **Audit Log Dumping Flag**.

Audit Log Dump is disabled by default. If is displayed, **Audit Log Dump** is enabled.

Step 4 Set the dump parameters based on information provided in **Table 10-29**

Table 10-29 Audit log dump parameters

Parameter	Description	Value
SFTP IP Mode	Mode of the destination IP address. The value can be **IPv4** or **IPv6**.	IPv4
SFTP IP	SFTP server for storing dumped audit logs. You are advised to use the SFTP service based on SSH v2 to prevent security risks.	**192.168.10.51** (example value)

Parameter	Description	Value
SFTP Port	Connection port of the SFTP server for storing dumped audit logs	**22** (example value)
Save Path	Path for storing audit logs on the SFTP server	**/opt/omm/oms/auditLog** (example value)
SFTP Username	User name for logging in to the SFTP server	**root** (example value)
SFTP Password	Password for logging in to the SFTP server	*Password for logging into the SFTP server*
SFTP Public key	Specifies the public key of the SFTP server. This parameter is optional. You are advised to set the public key of the SFTP server. Otherwise, security risks may exist.	-
Dumping Mode	Dump mode. Value options are as follows: • **By Quantity**: If the number of pieces of logs reaches the value of this parameter (**100000** by default), the logs are dumped. • **By Time**: specifies the date when logs are dumped. The dumping frequency is once a year.	• By Quantity • By Time
Dumping Date	This parameter is available only when **Dumping Mode** is set to **By time**. After you select a dump date, the system starts dumping on this date. The logs to be dumped include all the audit logs generated before January 1 00:00 of the current year.	11-06

NOTE

If the SFTP public key is empty, the system displays a security risk warning. Evaluate the security risk and then save the configuration.

Step 5 Click **OK** to complete the settings.

NOTE

Key fields in the audit log dump file are as follows:

- **USERTYPE** indicates the user type. Value **0** indicates a human-machine user, and value **1** indicates a machine-machine user.
- **LOGLEVEL** indicates the security level. Value **0** indicates Critical, value **1** indicates Major, value **2** indicates Minor, and value **3** indicates Warning.
- **OPERATERESULT** indicates the operation result. Value **0** indicates that the operation is successful, and value **1** indicates that the operation is failed.

----End

10.7 Tenant Resources

10.7.1 Multi-Tenancy

10.7.1.1 Overview

Definition

Multi-tenancy refers to multiple resource sets (a resource set is a tenant) in the MRS big data cluster and is able to allocate and schedule resources. The resources include computing resources and storage resources.

Context

Modern enterprises' data clusters are becoming more and more centralized and cloud-based. Enterprise-class big data clusters must meet the following requirements:

- Carry data of different types and formats and run jobs and applications of different types (such analysis, query, and stream processing).
- Isolate data of a user from that of another user who has demanding requirements on data security, such as a bank or government institute.

The preceding requirements bring the following challenges to the big data clusters:

- Proper allocation and scheduling of resources to ensure stable operating of applications and jobs.
- Strict access control to ensure data and service security.

Multi-tenancy isolates the resources of a big data cluster into resource sets. Users can lease desired resource sets to run applications and jobs and store data. In a big data cluster, multiple resource sets can be deployed to meet diverse requirements of multiple users.

The MRS big data cluster provides a complete enterprise-class big data multi-tenant solution.

Highlights

- Proper resource configuration and isolation

  The resources of a tenant are isolated from those of another tenant. The resource use of a tenant does not affect other tenants. This mechanism ensures that each tenant can configure resources based on service requirements, improving resource utilization.
- Resource consumption measurement and statistics

  Tenants are system resource applicants and consumers. System resources are planned and allocated based on tenants. Resource consumption by tenants can be measured and collected.
- Assured data security and access security

  In multi-tenant scenarios, the data of each tenant is stored separately to ensure data security. The access to tenants' resources is controlled to ensure access security.

10.7.1.2 Technical Principles

10.7.1.2.1 Multi-Tenant Management

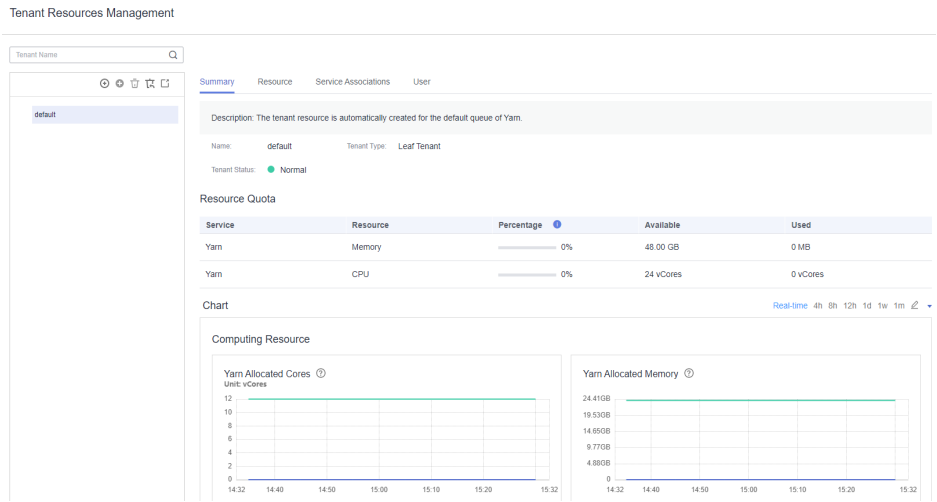
Unified Multi-Tenant Management

Log in to FusionInsight Manager and choose **Tenant Resources** > **Tenant Resources Management**. On the page that is displayed, you can find that FusionInsight Manager is a unified multi-tenant management platform that integrates multiple functions such as tenant lifecycle management, tenant resource configuration, tenant service association, and tenant resource usage statistics, delivering a mature multi-tenant management model and achieving centralized tenant and service management.

Graphical User Interface

FusionInsight Manager provides the graphical multi-tenant management interface and manages and operates multiple levels of tenants using the tree structure. Additionally, FusionInsight Manager integrates the basic information and resource quota of the current tenant in one interface to facilitate O&M and management.

Figure 10-12 Tenant management page of FusionInsight Manager



Hierarchical Tenant Management

FusionInsight Manager supports a hierarchical tenant management model in which you can add sub-tenants to an existing tenant to re-configure resources. Sub-tenants of level-1 tenants are level-2 tenants. So on and so forth. FusionInsight Manager provides enterprises with a field-tested multi-tenant management model, enabling centralized tenant and service management.

Simplified Permission Management

FusionInsight Manager hides internal permission management details from common users and simplifies permission management operations for administrators, improving usability and user experience of tenant permission management.

- FusionInsight Manager employs role-based access control (RBAC) to configure different permissions for users based on service scenarios during multi-tenant management.
- The administrator of tenants has tenant management permissions, including viewing resources and services of the current tenant, adding or deleting sub-tenants of the current tenant, and managing permissions of sub-tenants' resources. FusionInsight Manager supports setting of the administrator for a single tenant so that the management over this tenant can be delegated to a user who is not the system administrator.
- Roles of a tenant have all permissions on the computing resources and storage resources of the tenant. When a tenant is created, the system automatically creates roles for this tenant. You can add a user and bind the user to the tenant roles so that the user can use the resources of the tenant.

Clear Resource Management

- **Self-Service Resource Configuration**

  In FusionInsight Manager, you can configure the computing resources and storage resources during the creation of a tenant and add, modify, or delete the resources of the tenant.

  Permissions of the roles that are associated with a tenant are updated automatically when you modify the computing or storage resources of the tenant.

- **Resource Usage Statistics**

  Resource usage statistics are critical for administrators to determine O&M activities based on the status of cluster applications and services, improving the cluster O&M efficiency. FusionInsight Manager displays the resource statistics of tenants in **Resource Quota**, including the vCores, memory, and HDFS storage resources.

NOTE

- **Resource Quota** dynamically calculates the resource usage of tenants.

Service	Resource	Percentage	Available	Used
HDFS	Space	0.00%	20.00 GB	0 MB
Yarn	Memory	0.00%	8.00 GB	0 MB
Yarn	CPU	0.00%	4 vCores	0 vCores

  The available resources of the Superior scheduler are calculated as follows:

  - Superior

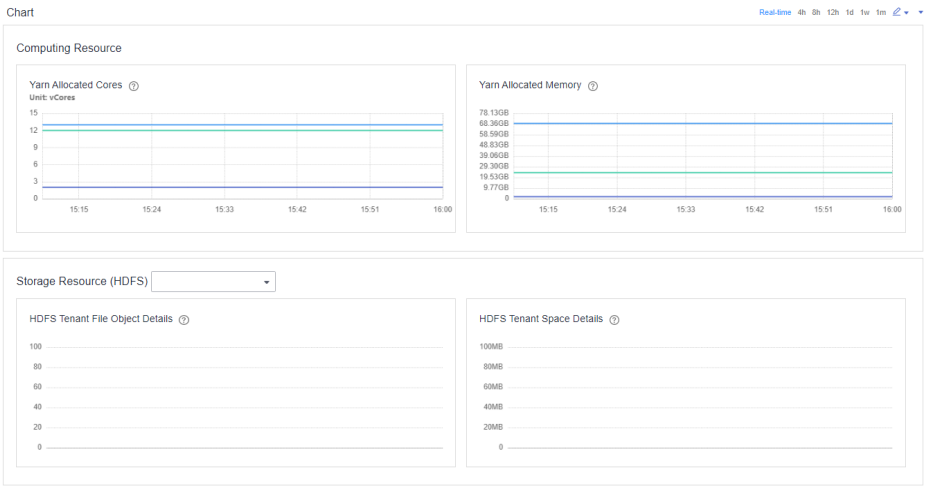
    The available Yarn resources (memory and CPU) are allocated in proportion based on the queue weight.

- When the tenant administrator is bound to a tenant role, the tenant administrator has the permissions to manage the tenant and use all resources of the tenant.

- **Graphical Resource Monitoring**

  Graphical resource monitoring supports the graphical display of monitoring metrics listed in **Table 10-30**, as shown in **Figure 10-13**.

Figure 10-13 Refined monitoring



By default, the real-time monitoring data is displayed. You can click to customize a time range. The default time ranges include 4 hours, 8 hours, 12 hours, 1 day, 1 week, and 1 month. Click and select **Export** to export the monitoring metric information.

Table 10-30 Monitoring metrics

Service	Metric Item	Description
HDFS	HDFS Tenant Space Details • Allocated Space • Used Space	HDFS can monitor a specified storage directory. The storage directory is the same as the directory added by the current tenant in **Resource**.

Service	Metric Item	Description
	HDFS Tenant File Object Details • Number of Used File Objects	
Yarn	Yarn Allocated Cores • Maximum Number of CPU Cores in an AM • Allocated Cores • Number of Used CPU Cores in an AM	Monitoring information of the current tenant is displayed. If no sub-item is configured for a tenant, this information is not displayed. The monitoring data is obtained from **Scheduler** > **Application Queues** > **Queue:** *Tenant name* on the native web UI of Yarn.
	Yarn Allocated Memory • Allocated Maximum AM Memory • Allocated Memory • Used AM Memory	

10.7.1.2.2 Multi-Tenant Model

Related Model

The following figure shows a multi-tenant model.

Figure 10-14 Multi-tenant model

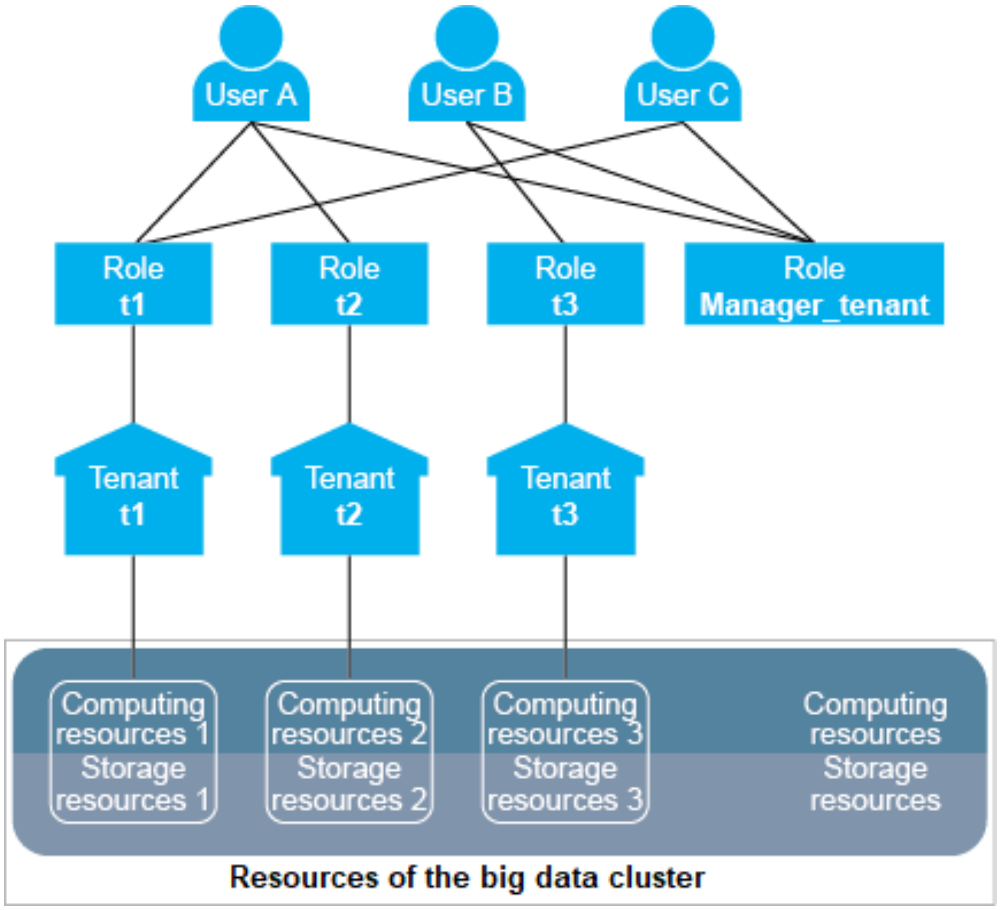


Table 10-31 describes the concepts involved in Figure 10-14.

Table 10-31 Concepts in the model

Concept	Description
User	A natural person who has a username and password and uses the big data cluster. There are three different users in Figure 10-14: user A, user B, and user C.
Role	A role is a carrier of one or more permissions. Permissions are assigned to specific objects, for example, access permissions for the **/tenant** directory in HDFS. Figure 10-14 shows four roles: **t1**, **t2**, **t3**, and **Manager_tenant**. • Roles **t1**, **t2**, and **t3** are automatically generated when tenants are created. The role names are the same as the tenant names. That is, roles **t1**, **t2**, and **t3** map to tenants **t1**, **t2**, and **t3**. Role names and tenant names need to be used in pair. • Role **Manager_tenant** is defaulted in the cluster and cannot be used separately.

Concept	Description
Tenant	A tenant is a resource set in a big data cluster. Multiple tenants are referred to as multi-tenancy. The resource sets further divided under a tenant are called sub-tenants. **Figure 10-14** shows three tenants: **t1**, **t2**, and **t3**.
Resource	• Computing resources include CPUs and memory. The computing resources of a tenant are allocated from the total computing resources in the cluster. One tenant cannot occupy the computing resources of another tenant. In **Figure 10-14**, computing resources 1, 2, and 3 are allocated for tenants **t1**, **t2**, and **t3** respectively from the cluster's computing resources. • Storage resources include disks and third-party storage systems. The storage resources of a tenant are allocated from the total storage resources in the cluster. One tenant cannot occupy the storage resources of another tenant. In **Figure 10-14**, storage resources 1, 2, and 3 are allocated for tenants **t1**, **t2**, and **t3** respectively from the cluster's storage resources.

If a user wants to use a tenant's resources or add or delete a sub-tenant of a tenant, the user needs to be bound to both the tenant role and role **Manager_tenant**. **Table 10-32** lists the roles bound to each user in **Figure 10-14**.

Table 10-32 Roles bound to each user

User	Role	Permission
User A	• Role **t1** • Role **t2** • Role **Manager_tenant**	• Uses the resources of tenants **t1** and **t2**. • Adds or deletes sub-tenants of tenants **t1** and **t2**.
User B	• Role **t3** • Role **Manager_tenant**	• Uses the resources of tenant **t3**. • Adds or deletes sub-tenants of tenant **t3**.
User C	• Role **t1** • Role **Manager_tenant**	• Uses the resources of tenant **t1**. • Adds or deletes sub-tenants of tenant **t1**.

A user can be bound to multiple roles, and one role can also be bound to multiple users. Users are associated with tenants after being bound to the tenant roles. Therefore, tenants and users form a many-to-many relationship. One user can use the resources of multiple tenants, and multiple users can use the resources of the

same tenant. For example, in **Figure 10-14**, user A uses the resources of tenants **t1** and **t2**, and users A and C uses the resources of tenant **t1**.

NOTE

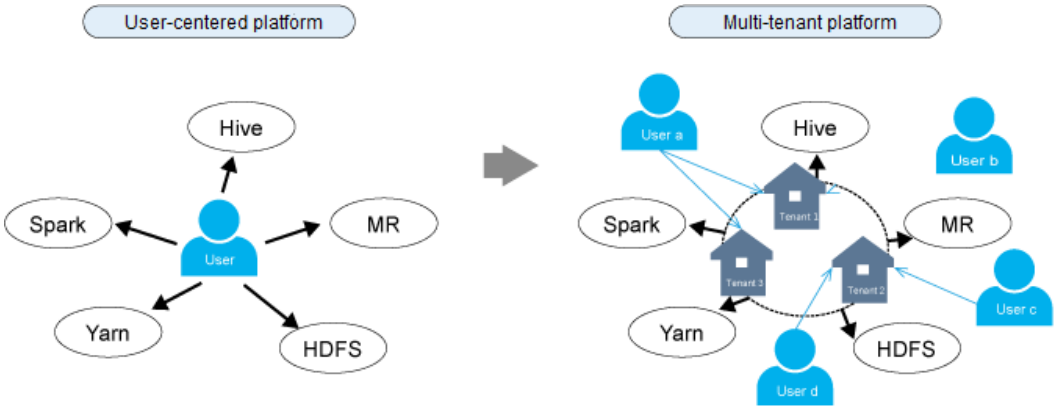
The concepts of a parent tenant, sub-tenant, level-1 tenant, and level-2 tenant are all designed for the multi-tenant service scenarios. Pay attention to the differences these concepts and the concepts of a leaf tenant and non-leaf tenant on FusionInsight Manager.

- Level-1 tenant: determined based on the tenant's level. For example, the first created tenant is a level-1 tenant and its sub-tenant is a level-2 tenant.
- Parent tenant and sub-tenant: indicates the hierarchical relationship between tenants.
- Non-leaf tenant: indicates the tenant type selected during tenant creation. This tenant type can be used to create sub-tenants.
- Leaf tenant: indicates the tenant type selected during tenant creation. This tenant type cannot be used to create sub-tenants.

Multi-Tenant Platform

Tenant is a core concept of the FusionInsight big data platform. It plays an important role in big data platforms' transformation from user-centered to multi-tenant to keep up with enterprises' multi-tenant application environments. **Figure 10-15** shows the transformation of big data platforms.

Figure 10-15 Platform transformation from user-centered to multi-tenant



On a user-centered big data platform, users can directly access and use all resources and services.

- However, user applications may use only partial cluster resources, resulting in low resource utilization.
- The data of different users may be stored together, decreasing data security.

On a multi-tenant big data platform, users use required resources and services by accessing the tenants.

- Resources are allocated and scheduled based on application requirements and used based on tenants, increasing resource utilization.
- Users can access the resources of tenants only after being associated with tenant roles, enhancing access security.
- The data of tenants is isolated, ensuring data security.

10.7.1.2.3 Resource Overview

MRS cluster resources are classified into compute resources and storage resources. The multi-tenant architecture implements resource isolation.

- **Computing resources**

  Computing resources include CPUs and memory. One tenant cannot occupy the computing resources of another tenant.

- **Storage resources**

  Storage resources include disks and third-party storage systems. One tenant cannot access the data of another tenant.

Computing Resources

Computing resources are divided into static service resources and dynamic resources.

- **Static Service Resources**

  Static service resources are computing resources allocated to each service and are not shared between services. The total computing resources of each service are fixed. These services include FTP-Server, Flume, HBase, HDFS, Solr, ClickHouse, and Yarn.

- **Dynamic Resources**

  Dynamic resources are computing resources dynamically scheduled to a job queue by the distributed resource management service Yarn. Yarn dynamically schedules resources for the job queues of MapReduce, Spark, Flink, and Hive.

NOTE

The resources allocated to Yarn in a big data cluster are static service resources but can be dynamically allocated to job queues by Yarn.

Storage Resources

Storage resources are data storage resources that can be allocated by the distributed file storage service HDFS. Directory is the basic unit of allocating HDFS storage resources. Tenants can obtain storage resources from the specified directories in the HDFS file system.

10.7.1.2.4 Dynamic Resources

Overview

Yarn provides distributed resource management for a big data cluster. The total volume of resources allocated to Yarn can be configured. Then Yarn allocates and schedules computing resources for job queues. The computing resources of MapReduce, Spark, Flink, and Hive job queues are allocated and scheduled by Yarn.

Yarn queues are fundamental units of scheduling computing resources.

The resources obtained by tenants using Yarn queues are dynamic resources. Users can dynamically create and modify the queue quotas and view the status and statistics of the queues.

Resource Pools

Nowadays, enterprise IT systems often face complex cluster environments and diverse upper-layer requirements. For example:

- Heterogeneous cluster: The computing speed, storage capacity, and network performance of each node in the cluster are different. All the tasks of complex applications need to be properly allocated to each compute node in the cluster based on service requirements.
- Computing isolation: Data must be shared among multiple departments but computing resources must be distributed onto different compute nodes.

These require that the compute nodes be further partitioned.

Resource pools are used to specify the configuration of dynamic resources. Yarn queues are associated with resource pools for resource allocation and scheduling.

One tenant can have only one default resource pool. Users can be bound to the role of a tenant to use the resources in the resource pool of the tenant. To use resources in multiple resource pools, a user can be bound to roles of multiple tenants.

Scheduling Mechanism

Yarn dynamic resources support label-based scheduling. This policy creates labels for compute nodes (Yarn NodeManagers) and adds the compute nodes with the same label into the same resource pool. Then Yarn dynamically associates the queues with resource pools based on the resource requirements of the queues.

For example, a cluster has more than 40 nodes which are labeled by **Normal**, **HighCPU**, **HighMEM**, or **HighIO** based on their hardware and network configurations and added into four resource pools, respectively. **Table 10-33** describes the performance of each node in the resource pool.

Table 10-33 Performance of each node in a resource pool

Label	Number of Nodes	Hardware and Network Configuration	Added To	Associated With
Normal	10	General	Resource pool A	Common queue
HighCPU	10	High-performance CPU	Resource pool B	Computing-intensive queue
HighMEM	10	Large memory	Resource pool C	Memory-intensive queue
HighIO	10	High-performance network	Resource pool D	I/O-intensive queue

A queue can use only the compute nodes in its associated resource pool.

- A common queue is associated with resource pool A and uses **Normal** nodes with general hardware and network configurations.
- A computing-intensive queue is associated with resource pool B and uses **HighCPU** nodes with high-performance CPUs.
- A memory-intensive queue is associated with resource pool C and uses **HighMEM** nodes with large memory.
- An I/O-intensive queue is associated with resource pool C and uses **HighIO** nodes with high-performance network.

Yarn queues are associated with specified resource pools to efficiently utilize resources in resource pools and maximize node performance.

FusionInsight Manager supports a maximum of 50 resource pools. The system has a default resource pool.

Schedulers

By default, the Superior scheduler is enabled for the MRS cluster.

- The Superior scheduler is an enhanced version and named after the Lake Superior, indicating that the scheduler can manage a large amount of data.

To meet enterprise requirements and tackle scheduling challenges faced by the Yarn community, the Superior scheduler makes the following enhancements:

- Enhanced resource sharing policy

  The Superior scheduler supports queue hierarchy. It integrates the functions of open-source schedulers and shares resources based on configurable policies. In terms of instances, administrators can use the Superior scheduler to configure an absolute value or percentage policy for queue resources. The resource sharing policy of the Superior scheduler enhances label-based scheduling of Yarn as a resource pool feature. The nodes in the Yarn cluster can be grouped based on the capacity or service type to ensure that queues can more efficiently utilize resources.
- Tenant-based resource reservation policy

  Some tenants may run critical tasks at some time, and their resource requirements must be preferentially addressed. The Superior scheduler builds a mechanism to support the resource reservation policy. Reserved resources can be allocated to the critical tasks running in the specified tenant queues in a timely manner to ensure proper task execution.
- Fair sharing among tenants and resource pool users

  The Superior scheduler allows shared resources to be configured for users in a queue. Each tenant may have users with different weights. Heavily weighted users may require more shared resources.
- Ensured scheduling performance in a big cluster

  The Superior scheduler receives heartbeats from each NodeManager and saves resource information in memory, which enables the scheduler to control cluster resource usage globally. The Superior scheduler uses the push scheduling model, which makes the scheduling more precise and efficient and remarkably improves cluster resource utilization. Additionally, the Superior

scheduler delivers excellent performance when the interval between NodeManager heartbeats is long and prevents heartbeat storms in big clusters.

- Priority policy

  If the minimum resource requirement of a service cannot be met after the service obtains all available resources, a preemption occurs. The preemption function is disabled by default.

10.7.1.2.5 Storage Resources

Overview

As a distributed file storage service in a big data cluster, HDFS stores all the user data of the upper-layer applications in the big data cluster, including the data written to HBase tables or Hive tables.

A directory is the basic unit of allocating HDFS storage resources. HDFS supports the conventional hierarchical file structure. Users or applications can create directories and create, delete, move, or rename files in directories. Tenants can obtain storage resources from specified directories in the HDFS file system.

Scheduling Mechanism

HDFS directories can be stored on nodes with specified labels or disks of specified hardware types. For example:

- When both real-time query and data analysis tasks are running in the same cluster, the real-time query tasks need to be deployed only on certain nodes, and the task data must also be stored on these nodes.
- Based on actual service requirements, key data needs to be stored on highly reliable nodes.

Administrators can flexibly configure HDFS data storage policies based on actual service requirements and data features to store data on specified nodes.

For tenants, storage resources refer to the HDFS resources they use. Data of specified directories can be stored to the tenant-specified storage paths, thereby implementing storage resource scheduling and ensuring data isolation between tenants.

Users can add or delete HDFS storage directories of tenants and set the file quantity quota and storage capacity quota of directories to manage storage resources.

10.7.1.3 Multi-Tenancy Usage

10.7.1.3.1 Overview

Tenants are used in resource control and service isolation scenarios. Administrators need to determine the service scenarios of cluster resources and then plan tenants.

NOTE

- Yarn in a new cluster uses the Superior scheduler by default. For details, see **Using the Superior Scheduler**.

Multi-tenancy involves three types of operations: creating a tenant, managing tenants, and managing resources. **Table 10-34** describes these operations.

Table 10-34 Multi-tenant operations

Operation	Action	Description
Creating a tenant	• Add a tenant. • Add a sub-tenant. • Create a user and bind the user to the role of a tenant.	During the creation of a tenant, you can configure its computing resources, storage resources, and associated services based on service requirements. In addition, you can add users to the tenant and bind necessary roles to these users. A user to create a level-1 tenant needs to be bound to the **Manager_administrator** or **System_administrator** role. A user to create a sub-tenant needs to be bound to the role of the parent tenant at least.
Managing tenants	• Manage the tenant directory. • Restore tenant data. • Clear non-associated queues of a tenant. • Delete a tenant.	You can edit tenants as services change. A user to manage or delete a level-1 tenant or restore tenant data needs to be bound to the **Manager_administrator** or **System_administrator** role. A user to manage or delete a sub-tenant needs to be bound to the role of the parent tenant at least.
Managing resources	• Create a resource pool. • Modify a resource pool. • Delete a resource pool. • Configure a queue. • Configure the queue capacity policy of a resource pool. • Clear configurations of a queue.	You can reconfigure resources for tenants as the services change. A user to manage resources needs to be bound to the **Manager_administrator** or **System_administrator** role.

10.7.1.3.2 Process Overview

Administrators need to determine the service scenarios of cluster resources and then plan tenants. After that, administrators add tenants and configure dynamic resources, storage resources, and associated services for the tenants on FusionInsight Manager.

Process Overview shows the process for creating a tenant.

Figure 10-16 Creating a tenant

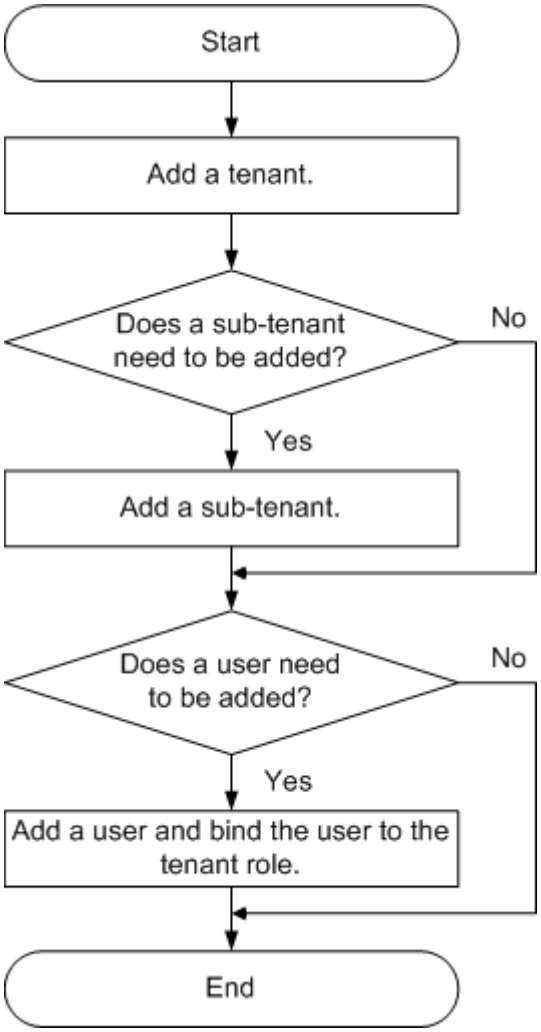


Table 10-35 describes the operations for creating a tenant.

Table 10-35 Operations for creating a tenant

Operation	Description
Add a tenant.	You can configure the computing resources, storage resources, and associated services of the tenant.

Operation	Description
Add a sub-tenant.	You can configure the computing resources, storage resources, and associated services of the sub-tenant.
Add a user and bind the user to the tenant role.	If a user wants to use the resources of tenant **tenant1** or add or delete sub-tenants for **tenant1**, the user must be bound to both the **Manager_tenant** and **tenant1**_*Cluster ID* roles.

10.7.2 Using the Superior Scheduler

10.7.2.1 Creating Tenants

10.7.2.1.1 Adding a Tenant

Scenario

You can create tenants on FusionInsight Manager based on the resource consumption and isolation planning and requirements of services.

Prerequisites

- A tenant name has been planned based on service requirements. The name cannot be the same as that of a role, HDFS directory, or Yarn queue that exists in the current cluster.
- Resources to be allocated to the current tenant have been planned to ensure that the sum of resources of direct sub-tenants at each level does not exceed the resources of the current tenant.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Tenant Resources**.

Step 2 Click ⊕. On the page that is displayed, configure tenant attributes according to **Table 10-36**.

Table 10-36 Tenant parameters

Parameter	Description
Name	• Indicates the name of the current tenant. The value consists of 3 to 50 characters, including digits, letters, and underscores (_). • Plan a tenant name based on service requirements. The name cannot be the same as that of a role, HDFS directory, or Yarn queue that exists in the current cluster.
Tenant Resource Type	Specifies whether the tenant is a leaf tenant. • When **Leaf Tenant** is selected, the current tenant is a leaf tenant and no sub-tenant can be added. • When **Non-leaf Tenant** is selected, the current tenant is not a leaf tenant and sub-tenants can be added to the current tenant. **NOTE** If you select **ClickHouse** for **Service**, this parameter can only be set to **Leaf Tenant**.
Computing Resource	Specifies the dynamic computing resources for the current tenant. • When **Yarn** is selected, the system automatically creates a queue in Yarn and the queue is named the same as the tenant name. – A leaf tenant can directly submit jobs to the queue. – A non-leaf tenant cannot directly submit jobs to the queue. However, Yarn adds an extra queue (hidden) named **default** for the non-leaf tenant to record the remaining resource capacity of the tenant. Actual jobs do not run in this queue. • If **Yarn** is not selected, the system does not automatically create a queue.
Configuration Mode	Indicates the configuration mode of computing resource parameters. • If you select **Basic**, you only need to set **Default Resource Pool Capacity (%)**. • If you select **Advanced**, you can manually configure the resource allocation weight and the minimum, maximum, and reserved resources of the tenant.
Default Resource Pool Capacity (%)	Indicates the percentage of computing resources used by the current tenant in the default resource pool. The value ranges from **0** to **100%**.

Parameter	Description
Weight	Indicates the resource allocation weight. The value ranges from **0** to **100**.
Minimum Resource	Indicates the resources guaranteed for the tenant (preemption supported). The value can be a percentage or an absolute value of the parent tenant's resources. When a tenant has a light workload, the resources of the tenant are automatically allocated to other tenants. When the available tenant resources are less than the value of **Minimum Resource**, the tenant can preempt the resources that have been lent to other tenants.
Maximum Resource	Indicates the maximum resources that can be used by the tenant. The tenant cannot obtain more resources than the value configured. The value can be a percentage or an absolute value of the parent tenant's resources.
Reserved Resource	Indicates the resources reserved for the tenant. The reserved resources cannot be used by other tenants even if no job is running in the current tenant resources. The value can be a percentage or an absolute value of the parent tenant's resources.
Storage Resource	Specifies storage resources for the current tenant. ● When **HDFS** is selected, the system automatically allocates storage resources. ● When **HDFS** is not selected, the system does not automatically allocate storage resources.
Quota	Indicates the quota for files and directories.
Space Quota	Indicates the quota for the HDFS storage space used by the current tenant. ● If the unit is set to **MB**, the value ranges from **1** to **8796093022208**. If the unit is set to **GB**, the value ranges from **1** to **8589934592**. ● This parameter indicates the maximum HDFS storage space that can be used by the tenant, but not the actual space used. ● If its value is greater than the size of the HDFS physical disk, the maximum space available is the full space of the HDFS physical disk.

Parameter	Description
Storage Path	Indicates the HDFS storage directory for the tenant. • The system automatically creates a folder named after the tenant name in the **/tenant** directory by default. For example, the default HDFS storage directory for tenant **ta1** is **/tenant/ta1**. • When a tenant is created for the first time, the system creates the **/tenant** directory in the HDFS root directory. The storage path is customizable.
Service	Specifies whether to associate resources of other services. For details, see **Step 4**.
Description	Indicates the description of the current tenant.

NOTE

Roles, computing resources, and storage resources are automatically created when tenants are created.

- The new role has permissions on the computing and storage resources. This role and its permissions are automatically controlled by the system and cannot be manually managed by choosing **System** > **Permission** > **Role**. The role name is in the format of *Tenant name_Cluster ID*. The ID of the first cluster is not displayed by default.
- When using this tenant, create a system user and bind the user to the role of the tenant. For details, see **Adding a User and Binding the User to a Tenant Role**.
- During the tenant creation, the system automatically creates a Yarn queue named after the tenant. If the queue name already exists, the new queue is named **Tenant name-***N*. *N* indicates a natural number starting from **1**. When a same name exists, the value *N* increases automatically to differentiate the queue from others. For example, **saletenant**, **saletenant-1**, and **saletenant-2**.

Step 3 Check whether the current tenant needs to be associated with resources of other services.

- If yes, go to **Step 4**.
- If no, go to **Step 5**.

Step 4 Click **Associate Service** to configure other service resources used by the current tenant, and click **OK**.

- Set **Service** to **HBase** and **Association Type** to **Exclusive** or **Shared**.

  NOTE

  - **Exclusive** indicates that the service resources are used by the tenant exclusively and cannot be associated with other tenants.
  - **Shared** indicates that the service resources can be shared with other tenants.

- Select **ClickHouse** for **Service**.
  - **Association Type**: Select **Exclusive** or **Shared**.
  - **Associate Logical Cluster**: If the logical cluster function is not enabled for ClickHouse, **default_cluster** is selected by default. If the function is enabled, select the logical cluster to which you want to associate.

- **CPU Priority**: The CPU priority ranges from –20 to 19. This value is associated with the NICE value of the OS. A smaller value indicates a higher CPU priority.
- **Memory**: The maximum value of this parameter is **100**, in percentage. For example, if this parameter is set to **80**, the total memory that can be used by the current tenant is calculated as follows: Available memory x 80%.
- **Concurrency**: The maximum number of concurrent resources available for all the users bound to the tenant.

NOTE

- HBase or ClickHouse can be associated with a new tenant. However, Yarn, ClickHouse, HDFS, and HBase can be associated with existing tenants.
- To associate an existing tenant with service resources, click the target tenant in the tenant list, switch to the **Service Associations** page, and click **Associate Service** to configure resources to be associated with the tenant.
- To disassociate an existing tenant from service resources, click the target tenant in the tenant list, switch to the **Service Associations** page, and click **Delete** in the **Operation** column. In the displayed dialog box, select **I have read the information and understand the impact** and click **OK**.

Step 5 Click **OK**. Wait until the system displays a message indicating that the tenant is successfully created.

You can click to export basic information about all tenants in the current cluster.

----End

10.7.2.1.2 Adding a Sub-Tenant

Scenario

You can create sub-tenants on FusionInsight Manager and allocate resources of the current tenant to the sub-tenants based on the resource consumption and isolation planning and requirements of services.

Prerequisites

- A parent non-leaf tenant has been added.
- A sub-tenant name has been planned based on service requirements. The name cannot be the same as that of a role, HDFS directory, or Yarn queue that exists in the current cluster.
- Resources to be allocated to the current tenant have been planned to ensure that the sum of resources of direct sub-tenants at each level does not exceed the resources of the current tenant.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Tenant Resources**.

Step 2 In the tenant list on the left, select a parent tenant and click . On the page for adding a sub-tenant, set attributes for the sub-tenant according to **Table 10-37**.

Table 10-37 Sub-tenant parameters

Parameter	Description
Cluster	Indicates the name of the current cluster.
Parent Tenant	Indicates the name of the parent tenant.
Name	• Indicates the name of the current tenant. The value consists of 3 to 50 characters, including digits, letters, and underscores (_). • Plan a sub-tenant name based on service requirements. The name cannot be the same as that of a role, HDFS directory, or Yarn queue that exists in the current cluster.
Tenant Type	Specifies whether the tenant is a leaf tenant. • When **Leaf Tenant** is selected, the current tenant is a leaf tenant and no sub-tenant can be added. • When **Non-leaf Tenant** is selected, the current tenant is not a leaf tenant and sub-tenants can be added to the current tenant. However, the tenant depth cannot exceed 5 levels. **NOTE** If you select **ClickHouse** for **Service**, this parameter can only be set to **Leaf Tenant**.
Computing Resource	Specifies the dynamic computing resources for the current tenant. • When **Yarn** is selected, the system automatically creates a queue in Yarn and the queue is named the same as the sub-tenant name. – A leaf tenant can directly submit jobs to the queue. – A non-leaf tenant cannot directly submit jobs to the queue. However, Yarn adds an extra queue (hidden) named **default** for the non-leaf tenant to record the remaining resource capacity of the tenant. Actual jobs do not run in this queue. • If **Yarn** is not selected, the system does not automatically create a queue.
Configuration Mode	Indicates the configuration mode of computing resource parameters. • If you select **Basic**, you only need to set **Default Resource Pool Capacity (%)**. • If you select **Advanced**, you can manually configure the resource allocation weight and the minimum, maximum, and reserved resources of the tenant.

Parameter	Description
Default Resource Pool Capacity (%)	Indicates the percentage of computing resources used by the current tenant. The base value is the total resources of the parent tenant.
Weight	Indicates the resource allocation weight. The value ranges from **0** to **100**.
Minimum Resource	Indicates the resources guaranteed for the tenant (preemption supported). The value can be a percentage or an absolute value of the parent tenant's resources. When a tenant has a light workload, the resources of the tenant are automatically allocated to other tenants. When the available tenant resources are less than the value of **Minimum Resource**, the tenant can preempt the resources that have been lent to other tenants.
Maximum Resource	Indicates the maximum resources that can be used by the tenant. The tenant cannot obtain more resources than the value configured. The value can be a percentage or an absolute value of the parent tenant's resources.
Reserved Resource	Indicates the resources reserved for the tenant. The reserved resources cannot be used by other tenants even if no job is running in the current tenant resources. The value can be a percentage or an absolute value of the parent tenant's resources.
Storage Resource	Specifies storage resources for the current tenant. ● When **HDFS** is selected, the system automatically creates a folder named after the sub-tenant in the HDFS parent tenant directory. ● When **HDFS** is not selected, the system does not automatically allocate storage resources.
Quota	Indicates the quota for files and directories.

Parameter	Description
Space Quota	Indicates the quota for the HDFS storage space used by the current tenant. • If the unit is set to **MB**, the value ranges from **1** to **8796093022208**. If the unit is set to **GB**, the value ranges from **1** to **8589934592**. • This parameter indicates the maximum HDFS storage space that can be used by the tenant, but not the actual space used. • If its value is greater than the size of the HDFS physical disk, the maximum space available is the full space of the HDFS physical disk. • If this quota is greater than the quota of the parent tenant, the actual storage space does not exceed the quota of the parent tenant.
Storage Path	Indicates the HDFS storage directory for the tenant. • The system automatically creates a folder named after the sub-tenant name in the directory of the parent tenant by default. For example, if the sub-tenant is **ta1s** and the parent directory is **/tenant/ta1**, the storage path for the sub-tenant is then **/tenant/ta1/ta1s**. • The storage path is customizable in the parent directory.
Service	Specifies whether to associate resources of other services. For details, see **Step 4**.
Description	Indicates the description of the current tenant.

NOTE

Roles, computing resources, and storage resources are automatically created when tenants are created.

- The new role has permissions on the computing and storage resources. This role and its permissions are automatically controlled by the system and cannot be manually managed by choosing **System** > **Permission** > **Role**. The role name is in the format of *Tenant name_Cluster ID*. The ID of the first cluster is not displayed by default.
- When using this tenant, create a system user and bind the user to the role of the tenant. For details, see **Adding a User and Binding the User to a Tenant Role**.
- The sub-tenant can further allocate the resources of its parent tenant. The sum of the resource percentages of direct sub-tenants under a parent tenant at each level cannot exceed 100%. The sum of the computing resource percentages of all level-1 tenants cannot exceed 100%.

Step 3 Check whether the current tenant needs to be associated with resources of other services.

- If yes, go to **Step 4**.

- If no, go to **Step 5**.

Step 4 Click **Associate Service** to configure other service resources used by the current tenant.

1. Set **Service** to **HBase** or **ClickHouse**.
2. Set **Association Type** as follows:
   - **Exclusive** indicates that the service resources are used by the tenant exclusively and cannot be associated with other tenants.
   - **Shared** indicates that the service resources can be shared with other tenants.

NOTE

- HBase or ClickHouse can be associated with a new tenant. However, HDFS, HBase, Yarn, and ClickHouse can be associated with existing tenants.
- To associate an existing tenant with service resources, click the target tenant in the tenant list, switch to the **Service Associations** page, and click **Associate Service** to configure resources to be associated with the tenant.
- To disassociate an existing tenant from service resources, click the target tenant in the tenant list, switch to the **Service Associations** page, and click **Delete** in the **Operation** column. In the displayed dialog box, select **I have read the information and understand the impact** and click **OK**.

3. Click **OK**.

Step 5 Click **OK**. Wait until the system displays a message indicating that the tenant is successfully created.

----End

10.7.2.1.3 Adding a User and Binding the User to a Tenant Role

Scenario

A newly created tenant cannot directly log in to the cluster to access resources. You need to add a user for the tenant on FusionInsight Manager and bind the user to the role of the tenant to assign operation permissions to the user.

Prerequisites

You have clarified service requirements and created a tenant.

Procedure

Step 1 Log in to FusionInsight Manager and choose **System** > **Permission** > **User**.

Step 2 If you want to add a user to the system, click **Create**.

If you want to bind tenant roles to an existing user in the system, locate the row of the user and click **Modify** in the **Operation** column.

Set user attributes according to **Table 10-38**.

Table 10-38 User parameters

Parameter	Description
Username	Indicates the current username. The value contains 3 to 32 characters, including digits, letters, underscores (_), hyphens (-), and spaces. ● The username cannot be the same as the OS username of any node in the cluster. Otherwise, the user cannot be used. ● A username that differs only in alphabetic case from an existing username is not allowed. For example, if **User1** has been created, you cannot create **user1**. Enter the correct username when using **User1**.
User Type	The options are **Human-Machine** and **Machine-Machine**. ● **Human-Machine** user: used for FusionInsight Manager O&M and component client operations. If you select this option, set both **Password** and **Confirm Password** accordingly. ● **Machine-Machine** user: used for application development. If you select this option, the password is randomly generated.
Password	This parameter is mandatory if **User Type** is set to **Human-Machine**. The password must contain 8 to 64 characters of at least four types of the following: uppercase letters, lowercase letters, digits, special characters, and spaces. The password cannot be the username or the username spelled backwards.
Confirm Password	Enter the password again.
User Group	In the **User Group** area, click **Add** and select user groups to add the user to the groups. ● If roles have been added to the user groups, the user can be granted the permissions of the roles. ● For example, add the user to the Hive user group to assign Hive permissions to the user.
Primary Group	Select a group as the primary group for the user to create directories and files. The drop-down list contains all groups selected in **User Group**.

Parameter	Description
Role	Click **Add** to bind a tenant role to the user. **NOTE** • If a user wants to use the resources of tenant **tenant1** and to add or delete sub-tenants for **tenant1**, the user must be bound to both the **Manager_tenant** and **tenant1**_*Cluster ID* roles. • If the tenant has been associated with the HBase service and Ranger authentication is enabled for the cluster, you need to configure the HBase execution permissions on the Ranger page.
Description	Indicates the description of the current user.

Step 3 Click **OK**.

----End

10.7.2.2 Managing Tenants

10.7.2.2.1 Managing Tenant Directories

Scenario

You can manage the HDFS storage directories used by specified tenants based on service requirements on FusionInsight Manager, such as adding tenant directories, changing the quotas for directories and files and for storage space, and deleting directories.

Prerequisites

A tenant with HDFS storage resources has been added.

Viewing a Tenant Directory

Step 1 Log in to FusionInsight Manager and choose **Tenant Resources**.

Step 2 In the tenant list on the left, click the target tenant.

Step 3 Click the **Resource** tab.

Step 4 View the **HDFS Storage** table.

- The **File Number Threshold** column provides the quota for files and directories of the tenant directory.
- The **Space Quota** column provides the storage space size of the tenant directory.

----End

Adding a Tenant Directory

Step 1 On FusionInsight Manager, choose **Tenant Resources**.

Step 2 In the tenant list on the left, click the target tenant.

Step 3 Click the **Resource** tab.

Step 4 In the **HDFS Storage** area, click **Create Directory**.

- **Parent Directory**: indicates the storage directory used by the parent tenant of the current tenant.

  NOTE

  This parameter is not displayed if the current tenant is not a sub-tenant.

- Set **Path** to a tenant directory path.

  NOTE

  If the current tenant is not a sub-tenant, the new path is created in the HDFS root directory.

- Set **Quota** to the quota for files and directories.
- **File Number Threshold (%)** is valid only when **Quota** is set. If the ratio of the number of used files to the value of **Quota** exceeds the value of this parameter, an alarm is generated. If this parameter is not specified, no alarm is reported in this scenario.

  NOTE

  The number of used files is collected every hour. Therefore, the alarm indicating that the ratio of used files exceeds the threshold is delayed.

- Set **Space Quota** to the storage space size of the tenant directory.
- If the ratio of used storage space to the value of **Space Quota** exceeds the **Storage Space Threshold (%)** value, an alarm is generated. If this parameter is not specified, no alarm is reported in this scenario.

  NOTE

  The used storage space is collected every hour. Therefore, the alarm indicating that the ratio of used storage space exceeds the threshold is delayed.

Step 5 Click **OK**.

----End

Modifying a Tenant Directory

Step 1 On FusionInsight Manager, choose **Tenant Resources**.

Step 2 In the tenant list on the left, click the target tenant.

Step 3 Click the **Resource** tab.

Step 4 In the **HDFS Storage** table, click **Modify** in the **Operation** column of the specified tenant directory.

- Set **Quota** to the quota for files and directories.
- **File Number Threshold (%)** is valid only when **Quota** is set. If the ratio of the number of used files to the value of **Quota** exceeds the value of this

parameter, an alarm is generated. If this parameter is not specified, no alarm is reported in this scenario.

- Set **Space Quota** to the storage space size of the tenant directory.
- If the ratio of used storage space to the value of **Space Quota** exceeds the **Storage Space Threshold (%)** value, an alarm is generated. If this parameter is not specified, no alarm is reported in this scenario.

Step 5 Click **OK**.

----End

Deleting a Tenant Directory

Step 1 On FusionInsight Manager, choose **Tenant Resources**.

Step 2 In the tenant list on the left, click the target tenant.

Step 3 Click the **Resource** tab.

Step 4 In the **HDFS Storage** table, click **Delete** in the **Operation** column of the specified tenant directory.

NOTE

The tenant directory that is created by the system during tenant creation cannot be deleted.

Step 5 Click **OK**.

----End

10.7.2.2.2 Restoring Tenant Data

Scenario

Tenant data is stored on FusionInsight Manager and cluster components. When components are recovered from failures or reinstalled, some configuration data of all tenants may become abnormal. In this case, you need to manually restore the configuration data on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Tenant Resources**.

Step 2 In the tenant list on the left, click the target tenant.

Step 3 Check the tenant data status.

1. On the **Summary** page, check **Tenant Status**. A green icon indicates that the tenant is available and gray indicates that the tenant is unavailable.
2. Click **Resource** and check the icons on the left of **Yarn** and **HDFS Storage**. A green icon indicates that the resource is available, and gray indicates that the resource is unavailable.
3. Click **Service Associations** and check the **Status** column of the associated services. **Normal** indicates that the component can provide services for the associated tenant. **Not Available** indicates that the component cannot provide services for the tenant.

4. If any of the preceding check items is abnormal, go to **Step 4** to restore tenant data.

Step 4 Click . In the displayed dialog box, enter the password of the current login user and click **OK**.

Step 5 In the **Restore Tenant Resource Data** window, select one or more components to restore data, and click **OK**. The system automatically restores the tenant data.

----End

10.7.2.2.3 Deleting a Tenant

Scenario

You can delete tenants that are no longer used on FusionInsight Manager based on service requirements to release resources occupied by the tenants.

Prerequisites

- A tenant has been added.
- The tenant has no sub-tenants. If the tenant has sub-tenants, delete them; otherwise, the tenant cannot be deleted.
- The role of the tenant is not associated with any user or user group.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Tenant Resources**.

Step 2 In the tenant list on the left, click the target tenant and click .

NOTE

- If you want to retain the tenant data, select **Reserve the data of this tenant resource**. Otherwise, the storage space of the tenant will be deleted.

Step 3 Click **OK**.

It takes a few minutes to save the configuration. After the tenant is deleted, the role and storage space of the tenant are also deleted.

NOTE

After the tenant is deleted, the queue of the tenant still exists in Yarn. The queue of the tenant is not displayed on the role management page in Yarn.

----End

10.7.2.3 Managing Resources

10.7.2.3.1 Adding a Resource Pool

Scenario

In a cluster, you can logically group Yarn NodeManagers into Yarn resource pools. Each NodeManager belongs to only one resource pool. You can create a custom

resource pool on FusionInsight Manager and add the hosts that have not been added to any custom resource pools to this resource pool so that specified queues can use the computing resources provided by these hosts.

The system contains a **default** resource pool by default. All NodeManagers that are not added to custom resource pools belong to this resource pool.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Tenant Resources** > **Resource Pool**.

Step 3 Click **Add Resource Pool**.

Step 4 Set resource pool attributes.

- **Name**: Enter the name of the resource pool. The name contains 1 to 50 characters, including digits, letters, and underscores (_), and cannot start with an underscore (_).
- **Resource Label**: Enter the resource label of the resource pool. The value can contain 1 to 50 characters, including digits, letters, underscores (_), and hyphens (-), and must start with a digit or letter.
- **Resource**: In the **Available Hosts** area, select specified hosts and click >> to add the hosts to the **Selected Hosts** area. Only hosts in the cluster can be selected. The host list in the resource pool can be left blank.

Step 5 Click **OK**.

After the resource pool is created, you can view its name, members, and mode in the resource pool list. Hosts that are added to the custom resource pool are no longer members of the **default** resource pool.

----End

10.7.2.3.2 Modifying a Resource Pool

Scenario

When hosts in a resource pool need to be adjusted based on service requirements, you can modify members in the resource pool on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Tenant Resources** > **Resource Pool**.

Step 3 In the resource pool list, locate the row containing the specified resource pool, and click **Modify** in the **Operation** column.

Step 4 In the **Resource** area, modify hosts.

- Adding hosts: Select desired hosts in **Available Hosts** and click >> to add them to the resource pool.

- Deleting hosts: Select desired hosts in **Selected Hosts** and click << to remove them from the resource pool. The host list in the resource pool can be left blank.

Step 5 Click **OK**.

----End

10.7.2.3.3 Deleting a Resource Pool

Scenario

If a resource pool is no longer used based on service requirements, you can delete it on FusionInsight Manager.

Prerequisites

- Any queue in the cluster does not use the resource pool to be deleted as the default resource pool. Before deleting the resource pool, cancel the default resource pool. For details, see **Configuring a Queue**.
- Resource distribution policies of all queues have been cleared from the resource pool to be deleted. For details, see **Clearing Queue Configurations**.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Tenant Resources** > **Resource Pool**.

Step 3 Locate the row that contains the specified resource pool, and click **Delete** in the **Operation** column.

Step 4 In the displayed dialog box, click **OK**.

----End

10.7.2.3.4 Configuring a Queue

Scenario

You can modify the queue configurations for a specified tenant on FusionInsight Manager.

Prerequisites

A tenant who uses the Superior scheduler has been added.

Procedure

Step 1 On FusionInsight Manager, choose **Tenant Resources**.

Step 2 Choose **Dynamic Resource Plan**.

Step 3 Click the **Queue Configurations** tab.

Step 4 Locate the row containing the specified tenant resource name and click **Modify** in the **Operation** column.

NOTE

- You can also access the **Modify Queue Configuration** page as follows: In the tenant list on the **Tenant Resources Management** page, click the target tenant, click the **Resource** tab, and click next to **Queue Configurations (*Queue name*)**.
- A queue can be bound to only one non-default resource pool.
- For parameters such as **Max Allocated vCores**, **Max Allocated Memory(MB)**, **Max Running Apps**, **Max Running Apps per User**, and **Max Pending Apps**, if the value of a sub-tenant is **-1**, the value of the parent tenant can be set to a specific limit. If the parent tenant value is a specific limit, the sub-tenant value can be set to **-1**.
- **Max Allocated vCores** and **Max Allocated Memory(MB)** must be both changed to values other than **-1**.
- For queues with cross-resource-pool scheduling enabled, existing resource pools cannot be deleted during job running. Otherwise, running jobs may be continuously blocked because they cannot apply for resources. Similarly, if a new resource pool is configured for a queue during job running, the queue in the running state may not immediately use the resources in the new resource pool. The new resources are available only to jobs submitted after modification.

Table 10-39 Queue configuration parameters

Parameter	Description
Max Master Shares(%)	Indicates the maximum percentage of resources occupied by all ApplicationMasters in the current queue.
Max Allocated vCores	Indicates the maximum number of cores that can be allocated to a single Yarn container in the current queue. The default value is **-1**, indicating that the number of cores is not limited within the value range.
Max Allocated Memory(MB)	Indicates the maximum memory that can be allocated to a single Yarn container in the current queue. The default value is **-1**, indicating that the memory is not limited within the value range.
Max Running Apps	Indicates the maximum number of tasks that can be executed at the same time in the current queue. The default value is **-1**, indicating that the number is not limited within the value range (the meaning is the same if the value is empty). Value **0** indicates that tasks cannot be executed. The value ranges from **-1** to **2147483647**.
Max Running Apps per User	Indicates the maximum number of tasks that can be executed by each user in the current queue at the same time. The default value is **-1**, indicating that the number is not limited within the value range (the meaning is the same if the value is empty). Value **0** indicates that tasks cannot be executed. The value ranges from **-1** to **2147483647**.

Parameter	Description
Max Pending Apps	Indicates the maximum number of tasks that can be suspended at the same time in the current queue. The default value is **-1**, indicating that the number is not limited within the value range (the meaning is the same if the value is empty). Value **0** indicates that tasks cannot be suspended. The value ranges from **-1** to **2147483647**.
Resource Allocation Rule	Indicates the rule for allocating resources to different tasks of a user. The rule can be **FIFO** or **FAIR**. If a user submits multiple tasks in the current queue and the rule is **FIFO**, the tasks are executed one by one in sequential order; If the rule is **FAIR**, resources are evenly allocated to all tasks.
Default Resource Label	Indicates that tasks are executed on a node with a specified resource label.
Cross-Pool Scheduling	Indicates whether containers in the current queue support cross-pool scheduling. This function cannot be enabled for the default queue.
Cross-Pool AM Scheduling	Indicates whether ApplicationMasters in the current queue support cross-pool scheduling. This function cannot be enabled for the default queue.
Active	• **ACTIVE**: indicates that the current queue can receive and execute tasks. • **INACTIVE**: indicates that the current queue can receive but cannot execute tasks. Tasks submitted to the queue are suspended.
Open	• **OPEN**: indicates that the current queue is opened. • **CLOSED**: indicates that the current queue is closed. Tasks submitted to the queue are rejected.
Migrate Queue Upon Fault	If cross-AZ HA is enabled for a cluster and an AZ is faulty, set **Migrate Queue Upon Fault** to **TRUE** to migrate running queues of the tenant to other AZs.

Step 5 Click **OK**.

----End

10.7.2.3.5 Configuring the Queue Capacity Policy of a Resource Pool

Scenario

After a resource pool is added, you can configure the capacity policy of available resources for Yarn queues so that jobs in the queues can be properly executed in the resource pool.

This section describes how to configure the queue policy on FusionInsight Manager. Tenant queues equipped with the Superior scheduler can use resources in different resource pools.

Prerequisites

- You have logged in to FusionInsight Manager.
- A resource pool has been added.
- The target queue is not associated with the resource pools of other queues except the default resource pool.

Procedure

Step 1 On FusionInsight Manager, choose **Tenant Resources**.

Step 2 Choose **Dynamic Resource Plan**.

Step 3 Click the **Resource Distribution Policy** tab.

Step 4 In **Resource Pools**, select a specified resource pool.

Step 5 Locate the row that contains the target queue in the **Resource Allocation** area, and click **Modify** in the **Operation** column.

Step 6 On the **Resource Configuration Policy** tab of the **Modify Resource Allocation** window, set the resource configuration policy of the queue in the resource pool.

- **Weight**: The task queue with a larger weight preempts resources first when resources are insufficient. Its initial value is the same as the minimum resource percentage.
- **Minimum Resource**: indicates the minimum resources that a tenant can obtain.
- **Maximum Resource**: indicates the maximum resources that a tenant can obtain.
- **Reserved Resource**: indicates the resources that are reserved for the tenant's queues and cannot be lent to other tenants' queues.

Step 7 Click the **User Policy** tab in the **Modify Resource Allocation** window and set the user policy.

NOTE

defaultUser(built-in) indicates that the policy specified for **defaultUser** is used if a user does not have a policy. The default policy cannot be deleted.

- Click **Add User Policy** to add a user policy.
  - **Username**: indicates the name of a user.
  - **Weight**: The task queue with a larger weight preempts resources first when resources are insufficient.
  - **Max vCores**: indicates the maximum number of virtual cores that the user can obtain.
  - **Max Memory(MB)**: indicates the maximum memory that the user can obtain.
- Click **Modify** in the **Operation** column to modify an existing user policy.

- Click **Clear** in the **Operation** column to delete an existing user policy.

Step 8 Click **OK**.

----End

10.7.2.3.6 Clearing Queue Configurations

Scenario

You can clear the configurations of a queue on FusionInsight MRS Manager when the queue does not need resources of a resource pool or the resource pool needs to be disassociated from the queue. Clearing queue configurations cancels the resource capacity policy of the queue in the resource pool.

Prerequisites

You have changed the default resource pool of the queue to another one. If a queue is to be disassociated from a resource pool, this resource pool cannot serve as the default resource pool of the queue. For details, see **Configuring a Queue**.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Tenant Resources** > **Dynamic Resource Plan**.

Step 3 In **Resource Pools**, select the target resource pool.

Step 4 Locate the row that contains the target resource name in the **Resource Allocation** area, and click **Clear** in the **Operation** column.

Step 5 In the displayed dialog box, click **OK** to clear the queue configurations from the current resource pool.

----End

10.7.2.4 Managing Global User Policies

Scenario

If a tenant uses a Superior scheduler, you can configure the global policy for users to use the resource scheduler, including:

- Maximum running apps
- Maximum pending apps
- Default queue

Procedure

- Add a policy.
  a. On FusionInsight Manager, choose **Tenant Resources**.
  b. Choose **Dynamic Resource Plan**.

c. Click the **Global User Policy** tab.

NOTE

defaults(default setting) indicates that the policy specified for **defaults** is used if a user does not have a global policy. The default policy cannot be deleted.

d. Click **Create Global User Policy**. In the displayed dialog box, set the following parameters:

- **Username**: indicates the user for whom resource scheduling is controlled. Enter an existing username in the current cluster.
- **Max Running Apps**: indicates the maximum number of tasks that the user can run in the current cluster.
- **Max Pending Apps**: indicates the maximum number of tasks that the user can suspend in the current cluster.
- **Default Queue**: indicates the queue of the user. Enter the name of an existing queue in the current cluster.

- Modify a policy.
  a. On FusionInsight Manager, choose **Tenant Resources**.
  b. Choose **Dynamic Resource Plan**.
  c. Click the **Global User Policy** tab.
  d. In the row that contains the desired user policy, click **Modify** in the **Operation** column.
  e. In the displayed dialog box, modify parameters and click **OK**.
- Delete a policy.
  a. On FusionInsight Manager, choose **Tenant Resources**.
  b. Choose **Dynamic Resource Plan**.
  c. Click the **Global User Policy** tab.
  d. In the row that contains the desired user policy, click **Delete** in the **Operation** column.

     In the displayed dialog box, click **OK**.

10.7.3 Using the Capacity Scheduler

10.7.3.1 Creating Tenants

10.7.3.1.1 Adding a Tenant

Scenario

You can create tenants on FusionInsight Manager based on the resource consumption and isolation planning and requirements of services.

Prerequisites

- A tenant name has been planned based on service requirements. The name cannot be the same as that of a role, HDFS directory, or Yarn queue that exists in the current cluster.
- Resources to be allocated to the current tenant have been planned to ensure that the sum of resources of direct sub-tenants at each level does not exceed the resources of the current tenant.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Tenant Resources**.

Step 2 Click . On the page that is displayed, configure tenant attributes according to **Table 10-40**.

Table 10-40 Tenant parameters

Parameter	Description
Name	• Indicates the name of the current tenant. The value consists of 3 to 50 characters, including digits, letters, and underscores (_). • Plan a tenant name based on service requirements. The name cannot be the same as that of a role, HDFS directory, or Yarn queue that exists in the current cluster.
Tenant Resource Type	Specifies whether the tenant is a leaf tenant. • When **Leaf Tenant** is selected, the current tenant is a leaf tenant and no sub-tenant can be added. • When **Non-leaf Tenant** is selected, the current tenant is not a leaf tenant and sub-tenants can be added to the current tenant. **NOTE** If you select **ClickHouse** for **Service**, this parameter can only be set to **Leaf Tenant**.

Parameter	Description
Computing Resource	Specifies the dynamic computing resources for the current tenant. ● When **Yarn** is selected, the system automatically creates a queue in Yarn and the queue is named the same as the tenant name. – A leaf tenant can directly submit jobs to the queue. – A non-leaf tenant cannot directly submit jobs to the queue. However, Yarn adds an extra queue (hidden) named **default** for the non-leaf tenant to record the remaining resource capacity of the tenant. Actual jobs do not run in this queue. ● If **Yarn** is not selected, the system does not automatically create a queue.
Configuration Mode	Indicates the configuration mode of computing resource parameters. ● If you select **Basic**, you only need to set **Default Resource Pool Capacity (%)**. ● If you select **Advanced**, you can manually configure the resource allocation weight and the minimum, maximum, and reserved resources of the tenant.
Default Resource Pool Capacity (%)	Indicates the percentage of computing resources used by the current tenant in the default resource pool. The value ranges from **0** to **100%**.
Weight	Indicates the resource allocation weight. The value ranges from **0** to **100**.
Minimum Resource	Indicates the resources guaranteed for the tenant (preemption supported). The value can be a percentage or an absolute value of the parent tenant's resources. When a tenant has a light workload, the resources of the tenant are automatically allocated to other tenants. When the available tenant resources are less than the value of **Minimum Resource**, the tenant can preempt the resources that have been lent to other tenants.
Maximum Resource	Indicates the maximum resources that can be used by the tenant. The tenant cannot obtain more resources than the value configured. The value can be a percentage or an absolute value of the parent tenant's resources.

Parameter	Description
Reserved Resource	Indicates the resources reserved for the tenant. The reserved resources cannot be used by other tenants even if no job is running in the current tenant resources. The value can be a percentage or an absolute value of the parent tenant's resources.
Storage Resource	Specifies storage resources for the current tenant. • When **HDFS** is selected, the system automatically allocates storage resources. • When **HDFS** is not selected, the system does not automatically allocate storage resources.
Quota	Indicates the quota for files and directories.
Space Quota	Indicates the quota for the HDFS storage space used by the current tenant. • If the unit is set to **MB**, the value ranges from **1** to **8796093022208**. If the unit is set to **GB**, the value ranges from **1** to **8589934592**. • This parameter indicates the maximum HDFS storage space that can be used by the tenant, but not the actual space used. • If its value is greater than the size of the HDFS physical disk, the maximum space available is the full space of the HDFS physical disk.
Storage Path	Indicates the HDFS storage directory for the tenant. • The system automatically creates a folder named after the tenant name in the **/tenant** directory by default. For example, the default HDFS storage directory for tenant **ta1** is **/tenant/ta1**. • When a tenant is created for the first time, the system creates the **/tenant** directory in the HDFS root directory. The storage path is customizable.
Service	Specifies whether to associate resources of other services. For details, see **Step 4**.
Description	Indicates the description of the current tenant.

NOTE

Roles, computing resources, and storage resources are automatically created when tenants are created.

- The new role has permissions on the computing and storage resources. This role and its permissions are automatically controlled by the system and cannot be manually managed by choosing **System** > **Permission** > **Role**. The role name is in the format of *Tenant name_Cluster ID*. The ID of the first cluster is not displayed by default.
- When using this tenant, create a system user and bind the user to the role of the tenant. For details, see **Adding a User and Binding the User to a Tenant Role**.
- During the tenant creation, the system automatically creates a Yarn queue named after the tenant. If the queue name already exists, the new queue is named **Tenant name-***N*. *N* indicates a natural number starting from **1**. When a same name exists, the value *N* increases automatically to differentiate the queue from others. For example, **saletenant**, **saletenant-1**, and **saletenant-2**.

Step 3 Check whether the current tenant needs to be associated with resources of other services.

- If yes, go to **Step 4**.
- If no, go to **Step 5**.

Step 4 Click **Associate Service** to configure other service resources used by the current tenant, and click **OK**.

- Set **Service** to **HBase** and **Association Type** to **Exclusive** or **Shared**.

  NOTE

  - **Exclusive** indicates that the service resources are used by the tenant exclusively and cannot be associated with other tenants.
  - **Shared** indicates that the service resources can be shared with other tenants.

- Select **ClickHouse** for **Service**.
  - **Association Type**: Select **Exclusive** or **Shared**.
  - **Associate Logical Cluster**: If the logical cluster function is not enabled for ClickHouse, **default_cluster** is selected by default. If the function is enabled, select the logical cluster to which you want to associate.
  - **CPU Priority**: The CPU priority ranges from –20 to 19. This value is associated with the NICE value of the OS. A smaller value indicates a higher CPU priority.
  - **Memory**: The maximum value of this parameter is **100**, in percentage. For example, if this parameter is set to **80**, the total memory that can be used by the current tenant is calculated as follows: Available memory x 80%.
  - **Concurrency**: The maximum number of concurrent resources available for all the users bound to the tenant.

NOTE

- HBase or ClickHouse can be associated with a new tenant. However, Yarn, ClickHouse, HDFS, and HBase can be associated with existing tenants.
- To associate an existing tenant with service resources, click the target tenant in the tenant list, switch to the **Service Associations** page, and click **Associate Service** to configure resources to be associated with the tenant.
- To disassociate an existing tenant from service resources, click the target tenant in the tenant list, switch to the **Service Associations** page, and click **Delete** in the **Operation** column. In the displayed dialog box, select **I have read the information and understand the impact** and click **OK**.

Step 5 Click **OK**. Wait until the system displays a message indicating that the tenant is successfully created.

You can click to export basic information about all tenants in the current cluster.

----End

10.7.3.1.2 Adding a Sub-Tenant

Scenario

You can create sub-tenants on FusionInsight Manager and allocate resources of the current tenant to the sub-tenants based on the resource consumption and isolation planning and requirements of services.

Prerequisites

- A parent non-leaf tenant has been added.
- A tenant name has been planned based on service requirements. The name cannot be the same as that of a role, HDFS directory, or Yarn queue that exists in the current cluster.
- Resources to be allocated to the current tenant have been planned to ensure that the sum of resources of direct sub-tenants at each level does not exceed the resources of the current tenant.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Tenant Resources**.

Step 2 In the tenant list on the left, select a parent tenant and click . On the page for adding a sub-tenant, set attributes for the sub-tenant according to **Table 10-41**.

Table 10-41 Sub-tenant parameters

Parameter	Description
Cluster	Indicates the name of the current cluster.
Parent Tenant	Indicates the name of the parent tenant.

Parameter	Description
Name	• Indicates the name of the current tenant. The value consists of 3 to 50 characters, including digits, letters, and underscores (_). • Plan a sub-tenant name based on service requirements. The name cannot be the same as that of a role, HDFS directory, or Yarn queue that exists in the current cluster.
Tenant Type	Specifies whether the tenant is a leaf tenant. • When **Leaf Tenant** is selected, the current tenant is a leaf tenant and no sub-tenant can be added. • When **Non-leaf Tenant** is selected, the current tenant is not a leaf tenant and sub-tenants can be added to the current tenant. However, the tenant depth cannot exceed 5 levels. **NOTE** If you select **ClickHouse** for **Service**, this parameter can only be set to **Leaf Tenant**.
Computing Resource	Specifies the dynamic computing resources for the current tenant. • When **Yarn** is selected, the system automatically creates a queue in Yarn and the queue is named the same as the sub-tenant name. – A leaf tenant can directly submit jobs to the queue. – A non-leaf tenant cannot directly submit jobs to the queue. However, Yarn adds an extra queue (hidden) named **default** for the non-leaf tenant to record the remaining resource capacity of the tenant. Actual jobs do not run in this queue. • If **Yarn** is not selected, the system does not automatically create a queue.
Configuration Mode	Indicates the configuration mode of computing resource parameters. • If you select **Basic**, you only need to set **Default Resource Pool Capacity (%)**. • If you select **Advanced**, you can manually configure the resource allocation weight and the minimum, maximum, and reserved resources of the tenant.
Default Resource Pool Capacity (%)	Indicates the percentage of computing resources used by the current tenant. The base value is the total resources of the parent tenant.

Parameter	Description
Weight	Indicates the resource allocation weight. The value ranges from **0** to **100**.
Minimum Resource	Indicates the resources guaranteed for the tenant (preemption supported). The value can be a percentage or an absolute value of the parent tenant's resources. When a tenant has a light workload, the resources of the tenant are automatically allocated to other tenants. When the available tenant resources are less than the value of **Minimum Resource**, the tenant can preempt the resources that have been lent to other tenants.
Maximum Resource	Indicates the maximum resources that can be used by the tenant. The tenant cannot obtain more resources than the value configured. The value can be a percentage or an absolute value of the parent tenant's resources.
Reserved Resource	Indicates the resources reserved for the tenant. The reserved resources cannot be used by other tenants even if no job is running in the current tenant resources. The value can be a percentage or an absolute value of the parent tenant's resources.
Storage Resource	Specifies storage resources for the current tenant. ● When **HDFS** is selected, the system automatically creates a folder named after the sub-tenant in the HDFS parent tenant directory. ● When **HDFS** is not selected, the system does not automatically allocate storage resources.
Quota	Indicates the quota for files and directories.
Space Quota	Indicates the quota for the HDFS storage space used by the current tenant. ● If the unit is set to **MB**, the value ranges from **1** to **8796093022208**. If the unit is set to **GB**, the value ranges from **1** to **8589934592**. ● This parameter indicates the maximum HDFS storage space that can be used by the tenant, but not the actual space used. ● If its value is greater than the size of the HDFS physical disk, the maximum space available is the full space of the HDFS physical disk. ● If this quota is greater than the quota of the parent tenant, the actual storage space does not exceed the quota of the parent tenant.

Parameter	Description
Storage Path	Indicates the HDFS storage directory for the tenant. • The system automatically creates a folder named after the sub-tenant name in the directory of the parent tenant by default. For example, if the sub-tenant is **ta1s** and the parent directory is **/tenant/ta1**, the storage path for the sub-tenant is then **/tenant/ta1/ta1s**. • The storage path is customizable in the parent directory.
Service	Specifies whether to associate resources of other services. For details, see **Step 4**.
Description	Indicates the description of the current tenant.

NOTE

Roles, computing resources, and storage resources are automatically created when tenants are created.

- The new role has permissions on the computing and storage resources. This role and its permissions are automatically controlled by the system and cannot be manually managed by choosing **System** > **Permission** > **Role**. The role name is in the format of *Tenant name_Cluster ID*. The ID of the first cluster is not displayed by default.
- When using this tenant, create a system user and bind the user to the role of the tenant. For details, see **Adding a User and Binding the User to a Tenant Role**.
- The sub-tenant can further allocate the resources of its parent tenant. The sum of the resource percentages of direct sub-tenants under a parent tenant at each level cannot exceed 100%. The sum of the computing resource percentages of all level-1 tenants cannot exceed 100%.

Step 3 Check whether the current tenant needs to be associated with resources of other services.

- If yes, go to **Step 4**.
- If no, go to **Step 5**.

Step 4 Click **Associate Service** to configure other service resources used by the current tenant.

1. Set **Service** to **HBase** or **ClickHouse**.
2. Set **Association Type** as follows:
   - **Exclusive** indicates that the service resources are used by the tenant exclusively and cannot be associated with other tenants.
   - **Shared** indicates that the service resources can be shared with other tenants.

NOTE

- HBase or ClickHouse can be associated with a new tenant. However, HDFS, HBase, Yarn, and ClickHouse can be associated with existing tenants.
- To associate an existing tenant with service resources, click the target tenant in the tenant list, switch to the **Service Associations** page, and click **Associate Service** to configure resources to be associated with the tenant.
- To disassociate an existing tenant from service resources, click the target tenant in the tenant list, switch to the **Service Associations** page, and click **Delete** in the **Operation** column. In the displayed dialog box, select **I have read the information and understand the impact** and click **OK**.

3. Click **OK**.

Step 5 Click **OK**. Wait until the system displays a message indicating that the tenant is successfully created.

----End

10.7.3.1.3 Adding a User and Binding the User to a Tenant Role

Scenario

A newly created tenant cannot directly log in to the cluster to access resources. You need to add a user for the tenant on FusionInsight Manager and bind the user to the role of the tenant to assign operation permissions to the user.

Prerequisites

You have clarified service requirements and created a tenant.

Procedure

Step 1 Log in to FusionInsight Manager and choose **System** > **Permission** > **User**.

Step 2 If you want to add a user to the system, click **Create**.

If you want to bind tenant roles to an existing user in the system, locate the row of the user and click **Modify** in the **Operation** column.

Set user attributes according to **Table 10-42**.

Table 10-42 User parameters

Parameter	Description
Username	Specifies the current user name. The value can contain 3 to 32 characters, including digits, letters, underscores (_), hyphens (-), and spaces. ● The username cannot be the same as the OS username of any node in the cluster. Otherwise, the user cannot be used. ● A username that differs only in alphabetic case from an existing username is not allowed. For example, if **User1** has been created, you cannot create **user1**. Enter the correct username when using **User1**.
User Type	The options are **Human-Machine** and **Machine-Machine**. ● **Human-Machine** user: used for FusionInsight Manager O&M and component client operations. If you select this option, set both **Password** and **Confirm Password** accordingly. ● **Machine-Machine** user: used for application development. If you select this option, the password is randomly generated.
Password	This parameter is mandatory if **User Type** is set to **Human-Machine**. The password must contain 8 to 64 characters of at least four types of the following: uppercase letters, lowercase letters, digits, special characters, and spaces. The password cannot be the username or the username spelled backwards.
Confirm Password	Enter the password again.
User Group	In the **User Group** area, click **Add** and select user groups to add the user to the groups. ● If roles have been added to the user groups, the user can be granted the permissions of the roles. ● For example, add the user to the Hive user group to assign Hive permissions to the user.
Primary Group	Select a group as the primary group for the user to create directories and files. The drop-down list contains all groups selected in **User Group**.
Role	Click **Add** to bind a tenant role to the user. **NOTE** If a user wants to use the resources of tenant **tenant1** and to add or delete sub-tenants for **tenant1**, the user must be bound to both the **Manager_tenant** and **tenant1**_*Cluster ID* roles.

Parameter	Description
Description	Indicates the description of the current user.

Step 3 Click **OK**.

----End

10.7.3.2 Managing Tenants

10.7.3.2.1 Managing Tenant Directories

Scenario

You can manage the HDFS storage directories used by specified tenants based on service requirements on FusionInsight Manager, such as adding tenant directories, changing the quotas for directories and files and for storage space, and deleting directories.

Prerequisites

A tenant with HDFS storage resources has been added.

Viewing a Tenant Directory

Step 1 On FusionInsight Manager, choose **Tenant Resources**.

Step 2 In the tenant list on the left, click the target tenant.

Step 3 Click the **Resource** tab.

Step 4 View the **HDFS Storage** table.

- The **File Number Threshold** column provides the quota for files and directories of the tenant directory.
- The **Space Quota** column provides the storage space size of the tenant directory.

----End

Adding a Tenant Directory

Step 1 On FusionInsight Manager, choose **Tenant Resources**.

Step 2 In the tenant list on the left, click the target tenant.

Step 3 Click the **Resource** tab.

Step 4 In the **HDFS Storage** area, click **Create Directory**.

- **Parent Directory**: indicates the storage directory used by the parent tenant of the current tenant.

  NOTE

  This parameter is not displayed if the current tenant is not a sub-tenant.

- Set **Path** to a tenant directory path.

  NOTE

  If the current tenant is not a sub-tenant, the new path is created in the HDFS root directory.

- Set **Quota** to the quota for files and directories.
- **File Number Threshold (%)** is valid only when **Quota** is set. If the ratio of the number of used files to the value of **Quota** exceeds the value of this parameter, an alarm is generated. If this parameter is not specified, no alarm is reported in this scenario.

  NOTE

  The number of used files is collected every hour. Therefore, the alarm indicating that the ratio of used files exceeds the threshold is delayed.

- Set **Space Quota** to the storage space size of the tenant directory.
- If the ratio of used storage space to the value of **Space Quota** exceeds the **Storage Space Threshold (%)** value, an alarm is generated. If this parameter is not specified, no alarm is reported in this scenario.

  NOTE

  The used storage space is collected every hour. Therefore, the alarm indicating that the ratio of used storage space exceeds the threshold is delayed.

Step 5 Click **OK**.

----End

Modifying a Tenant Directory

Step 1 On FusionInsight Manager, choose **Tenant Resources**.

Step 2 In the tenant list on the left, click the target tenant.

Step 3 Click the **Resource** tab.

Step 4 In the **HDFS Storage** table, click **Modify** in the **Operation** column of the specified tenant directory.

- Set **Quota** to the quota for files and directories.
- **File Number Threshold (%)** is valid only when **Quota** is set. If the ratio of the number of used files to the value of **Quota** exceeds the value of this parameter, an alarm is generated. If this parameter is not specified, no alarm is reported in this scenario.
- Set **Space Quota** to the storage space size of the tenant directory.
- If the ratio of used storage space to the value of **Space Quota** exceeds the **Storage Space Threshold (%)** value, an alarm is generated. If this parameter is not specified, no alarm is reported in this scenario.

Step 5 Click **OK**.

----End

Deleting a Tenant Directory

Step 1 On FusionInsight Manager, choose **Tenant Resources**.

Step 2 In the tenant list on the left, click the target tenant.

Step 3 Click the **Resource** tab.

Step 4 In the **HDFS Storage** table, click **Delete** in the **Operation** column of the specified tenant directory.

NOTE

The tenant directory that is created by the system during tenant creation cannot be deleted.

Step 5 Click **OK**.

----End

10.7.3.2.2 Restoring Tenant Data

Scenario

Tenant data is stored on FusionInsight Manager and cluster components. When components are recovered from failures or reinstalled, some configuration data of all tenants may become abnormal. In this case, you need to manually restore the configuration data on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Tenant Resources**.

Step 2 In the tenant list on the left, click the target tenant.

Step 3 Check the tenant data status.

1. On the **Summary** page, check **Tenant Status**. A green icon indicates that the tenant is available and gray indicates that the tenant is unavailable.
2. Click **Resource** and check the icons on the left of **Yarn** and **HDFS Storage**. A green icon indicates that the resource is available, and gray indicates that the resource is unavailable.
3. Click **Service Associations** and check the **Status** column of the associated services. **Normal** indicates that the component can provide services for the associated tenant. **Not Available** indicates that the component cannot provide services for the tenant.
4. If any of the preceding check items is abnormal, go to **Step 4** to restore tenant data.

Step 4 Click . In the displayed dialog box, enter the password of the current login user and click **OK**.

Step 5 In the **Restore Tenant Resource Data** window, select one or more components to restore data, and click **OK**. The system automatically restores the tenant data.

----End

10.7.3.2.3 Deleting a Tenant

Scenario

You can delete tenants that are no longer used on FusionInsight Manager based on service requirements to release resources occupied by the tenants.

Prerequisites

- A tenant has been added.
- The tenant has no sub-tenants. If the tenant has sub-tenants, delete them; otherwise, the tenant cannot be deleted.
- The role of the tenant is not associated with any user or user group.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Tenant Resources**.

Step 2 In the tenant list on the left, click the target tenant and click .

NOTE

- If you want to retain the tenant data, select **Reserve the data of this tenant resource**. Otherwise, the storage space of the tenant will be deleted.
- To delete a tenant without retaining the tenant data as a user who does not belong to the supergroup, you should first log in to the HDFS client as a user who belongs to the supergroup and then manually clear the storage space of that tenant to avoid residual data.

Step 3 Click **OK**.

It takes a few minutes to save the configuration. After the tenant is deleted, the role and storage space of the tenant are also deleted.

NOTE

After the tenant is deleted, the queue of the tenant still exists in Yarn. The queue of the tenant is not displayed on the role management page in Yarn.

----End

10.7.3.2.4 Clearing Non-associated Queues of a Tenant

Scenario

If Yarn uses the Capacity scheduler, deleting a tenant only sets the queue capacity of the tenant to **0** and the tenant status to **STOPPED** but does not clear the queues of the tenant in Yarn. Limited by the Yarn mechanism, queues cannot be dynamically deleted. You can run commands to manually delete residual queues.

Impact on the System

- During the script execution, the Controller service is restarted, Yarn configurations are synchronized, and the active and standby ResourceManagers are restarted.
- FusionInsight Manager becomes inaccessible during the restart of the Controller service.

- After the active and standby ResourceManagers are restarted, an alarm is generated indicating that Yarn and components that depend on Yarn are temporarily unavailable.

Prerequisites

Queues of a deleted tenant still exist.

Procedure

Step 1 Check that queues of the deleted tenant still exist.

1. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Yarn**. Click the link of the active ResourceManager in **ResourceManager WebUI** to go to the ResourceManager web UI.
2. Click **Scheduler** in the navigation tree on the left. In the right pane, you can view that queues of the tenant still exist in the **STOPPED** state and their **Configured Capacity** is **0**.

Step 2 Log in to the active management node as user **omm**.

Step 3 Switch the directory and execute the **cleanQueuesAndRestartRM.sh** script.

cd ${BIGDATA_HOME}/om-server/om/sbin

./cleanQueuesAndRestartRM.sh -c *Cluster ID*

NOTE

You can choose **Cluster** > **Cluster Properties** on FusionInsight Manager to view the cluster ID.

During the script execution, you need to enter **yes** and the password.

```
Running the script will restart Controller and restart ResourceManager.
Are you sure you want to continue connecting (yes/no)?yes
Please input admin password:
Begin to backup queues ...
...
```

Step 4 After the script is executed successfully, choose **Cluster** > **Services** > **Yarn** on FusionInsight Manager. Click the link of the active ResourceManager in **ResourceManager WebUI** to go to the ResourceManager web UI.

Step 5 Click **Scheduler** in the navigation tree on the left. In the right pane, you can view that queues of the tenant have been cleared.

----End

10.7.3.3 Managing Resources

10.7.3.3.1 Adding a Resource Pool

Scenario

In a cluster, you can logically group Yarn NodeManagers into Yarn resource pools. Each NodeManager belongs to only one resource pool. You can create a custom

resource pool on FusionInsight Manager and add the hosts that have not been added to any custom resource pools to this resource pool so that specified queues can use the computing resources provided by these hosts.

The system contains a **default** resource pool by default. All NodeManagers that are not added to custom resource pools belong to this resource pool.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Tenant Resources** > **Resource Pool**.

Step 3 Click **Add Resource Pool**.

Step 4 Set resource pool attributes.

- **Name**: Enter the name of the resource pool. The name contains 1 to 50 characters, including digits, letters, and underscores (_), and cannot start with an underscore (_).
- **Resource Label**: Enter the resource label of the resource pool. The value can contain 1 to 50 characters, including digits, letters, underscores (_), and hyphens (-), and must start with a digit or letter.
- **Resource**: In the **Available Hosts** area, select specified hosts and click >> to add the hosts to the **Selected Hosts** area. Only hosts in the cluster can be selected. The host list in the resource pool can be left blank.

Step 5 Click **OK**.

After the resource pool is created, you can view its name, members, and mode in the resource pool list. Hosts that are added to the custom resource pool are no longer members of the **default** resource pool.

----End

10.7.3.3.2 Modifying a Resource Pool

Scenario

When hosts in a resource pool need to be adjusted based on service requirements, you can modify members in the resource pool on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Tenant Resources** > **Resource Pool**.

Step 3 In the resource pool list, locate the row containing the specified resource pool, and click **Modify** in the **Operation** column.

Step 4 In the **Resource** area, modify hosts.

- Adding hosts: Select desired hosts in **Available Hosts** and click >> to add them to the resource pool.

- Deleting hosts: Select desired hosts in **Selected Hosts** and click << to remove them from the resource pool. The host list in the resource pool can be left blank.

Step 5 Click **OK**.

----End

10.7.3.3.3 Deleting a Resource Pool

Scenario

If a resource pool is no longer used based on service requirements, you can delete it on FusionInsight Manager.

Prerequisites

- Any queue in the cluster does not use the resource pool to be deleted as the default resource pool. Before deleting the resource pool, cancel the default resource pool. For details, see **Configuring a Queue**.
- Resource distribution policies of all queues have been cleared from the resource pool to be deleted. For details, see **Clearing Queue Configurations**.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Tenant Resources** > **Resource Pool**.

Step 3 Locate the row that contains the specified resource pool, and click **Delete** in the **Operation** column.

Step 4 In the displayed dialog box, click **OK**.

----End

10.7.3.3.4 Configuring a Queue

Scenario

You can modify the queue configurations for a specified tenant on FusionInsight Manager.

Prerequisites

A tenant who uses the Capacity scheduler has been added.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Tenant Resources** > **Dynamic Resource Plan**.

The **Resource Distribution Policy** page is displayed by default.

Step 3 Click the **Queue Configurations** tab.

Step 4 Locate the row containing the specified tenant resource name and click **Modify** in the **Operation** column.

NOTE

- You can also access the **Modify Queue Configuration** page as follows: In the tenant list on the **Tenant Resources Management** page, click the target tenant, click the **Resource** tab, and click  next to **Queue Configurations (***Queue name***)**.
- A queue can be bound to only one non-default resource pool. That is, a newly added resource pool can be bound to only one queue to serve as the default resource pool of the queue.

Table 10-43 Queue configuration parameters

Parameter	Description
Tenant Resources Name (Queue)	Indicates the tenant name and queue name.
Maximum Applications	Indicates the maximum number of applications.
Maximum AM Resource Percent	Indicates the maximum percentage of resources that can be used to run the ApplicationMaster in a cluster.
Minimum User Resource Upper-Limit Percent (%)	Indicates the minimum resource guarantee (percentage) of a user. The resources for each user in a queue are limited at any time. If applications of multiple users are running at the same time in a queue, the resource usage of each user fluctuates between the minimum value and the maximum value. The minimum value is determined by the number of running applications, while the maximum value is determined by this parameter. For example, assume that this parameter is set to **25**. If two users submit applications to the queue, each user can use a maximum of 50% resources; if three users submit applications to the queue, each user can use a maximum of 33% resources; if four users submit applications to the queue, each user can use a maximum of 25% resources.
User Resource Upper-Limit Factor	Indicates the limit factor of the maximum user resource usage. The maximum user resource usage percentage can be obtained by multiplying the limit factor with the percentage of the tenant's actual resource usage in the cluster.
Status	Indicates the current status of a resource plan. The value can be **Running** or **Stopped**.

Parameter	Description
Default Resource Pool	Indicates the resource pool used by the queue. The default value is **default**. If you want to change the resource pool, configure the queue capacity first. For details, see **Configuring the Queue Capacity Policy of a Resource Pool**.

Step 5 Click **OK**.

----End

10.7.3.3.5 Configuring the Queue Capacity Policy of a Resource Pool

Scenario

After a resource pool is added, you can configure the capacity policy of available resources for Yarn queues so that jobs in the queues can be properly executed in the resource pool. A queue can have the queue capacity policy of only one resource pool.

You can view queues and configure queue capacity policies in any resource pool. After the queue policies are configured, Yarn queues are associated with resource pools.

Prerequisites

A queue has been added, that is, a tenant associated with computing resources has been created.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Tenant Resources** > **Dynamic Resource Plan**.

The **Resource Distribution Policy** page is displayed by default.

Step 3 In **Resource Pools**, select the target resource pool.

Step 4 Locate the row that contains the target resource name in the **Resource Allocation** area, and click **Modify** in the **Operation** column.

Step 5 In the **Modify Resource Allocation** window, configure the resource capacity policy of the queue in the resource pool.

- **Capacity (%)**: indicates the percentage of computing resources used by the current tenant.
- **Maximum Capacity (%)**: indicates the maximum percentage of computing resources used by the current tenant.

Step 6 Click **OK**.

NOTE

After the resource capacity values of a queue are deleted and saved, the resource capacity policy of the queue in the resource pool is canceled, indicating that the queue is disassociated from the resource pool. To achieve this, you need to change the default resource pool of the queue to another one. For details, see **Configuring a Queue**.

----End

10.7.3.3.6 Clearing Queue Configurations

Scenario

You can clear the configurations of a queue on FusionInsight MRS Manager when the queue does not need resources of a resource pool or the resource pool needs to be disassociated from the queue. Clearing queue configurations cancels the resource capacity policy of the queue in the resource pool.

Prerequisites

You have changed the default resource pool of the queue to another one. If a queue is to be disassociated from a resource pool, this resource pool cannot serve as the default resource pool of the queue. For details, see **Configuring a Queue**.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Tenant Resources** > **Dynamic Resource Plan**.

Step 3 In **Resource Pools**, select the target resource pool.

Step 4 Locate the row that contains the target resource name in the **Resource Allocation** area, and click **Clear** in the **Operation** column.

Step 5 In the displayed dialog box, click **OK** to clear the queue configurations from the current resource pool.

----End

10.7.4 Switching the Scheduler

Scenario

The newly installed MRS cluster uses the Superior scheduler by default. If the cluster is upgraded from an earlier version, you can switch between the Capacity scheduler and the Superior scheduler.

Prerequisites

- The network connectivity of the cluster is proper and secure, and the Yarn service status is normal.
- During scheduler switching, tenants cannot be added, deleted, or modified. In addition, services cannot be started or stopped.

Switching Between the Capacity Scheduler and Superior Scheduler

Constraints

- This operation applies only to the scenario where a cluster is newly provisioned and the scheduler needs to be switched.
- During the scheduler switchover, do not perform any operation on the cluster. Otherwise, the operation may fail due to database modification.

Impact on the system

- Because the ResourceManager is restarted during scheduler switching, submitting jobs to Yarn will fail at that time.
- After the scheduler is switched, the parameters of the scheduler that takes over the workload are used.

Procedure

Step 1 Log in to FusionInsight Manager. Choose **Cluster** > **Services** > **Yarn** and check whether the Yarn service status is normal. If the service is abnormal, restore the service.

Step 2 Log in to the active management node as user **omm**.

Step 3 Switch the scheduler.

- Run the following command to switch from the Capacity scheduler to the Superior scheduler:

  sh ${BIGDATA_HOME}/om-server/om/sbin/cleanSwitchScheduler.sh 1

  If information similar to the following is displayed, the switch is successful:

  ```
  Will change scheduler type to SUPERIOR
  Start to delete all tenant resource.
  End to delete all tenant resource.
  Start to delete all resource pool.
  End to delete all resource pool.
  ...
  End to switch scheduler by reset.
  ```

- Run the following command to switch from the Capacity scheduler to the Superior scheduler:

  sh ${BIGDATA_HOME}/om-server/om/sbin/cleanSwitchScheduler.sh 0

  If information similar to the following is displayed, the switch is successful:

  ```
  Will change scheduler type to CAPACITY
  Start to delete all tenant resource.
  End to delete all tenant resource.
  Start to delete all resource pool.
  End to delete all resource pool.
  ...
  End to switch scheduler by reset.
  ```

  NOTE

  You can query the scheduler switching logs on the active management node.

  - ${BIGDATA_LOG_HOME}/controller/aos/clean_switch_scheduler.log
  - ${BIGDATA_LOG_HOME}/controller/aos/aos.log
  - ${BIGDATA_LOG_HOME}/controller/aos/plugin.log

----End

Switching from the Capacity Scheduler to the Superior Scheduler

Impact on the system

- Because the ResourceManager is restarted during scheduler switching, submitting jobs to Yarn will fail at that time.
- During scheduler switching, tasks in a job being executed on Yarn will continue, but new tasks cannot be started.
- After scheduler switching is complete, jobs executed on Yarn may fail, causing service interruptions.
- After scheduler switching is complete, parameters of the Superior scheduler are used for tenant management.
- After scheduler switching is complete, tenant queues whose capacity is 0 in the Capacity scheduler cannot be allocated resources in the Superior scheduler. As a result, jobs submitted to these tenant queues fail to be executed. Therefore, you are advised not to set the capacity of a tenant queue to 0 in the Capacity scheduler.
- After scheduler switching is complete, you cannot add or delete resource pools, Yarn node labels, or tenants during the observation period. If such an operation is performed, the scheduler cannot be rolled back to the Capacity scheduler.

  NOTE

  - The recommended observation period for scheduler switching is one week. If resource pools, Yarn node labels, or tenants are added or deleted during this period, the observation period ends immediately.
- Rollback may cause the loss of partial or all Yarn job information.

Procedure

Step 1 Modify Yarn service parameters and ensure that the Yarn service status is normal.

1. Log in to FusionInsight Manager as an administrator.
2. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Yarn**. Click **Configurations** then **All Configurations**, search for **yarn.resourcemanager.webapp.pagination.enable**, and check whether the value is **true**.
   - If yes, go to **Step 1.3**.
   - If no, set the parameter to **true** and click **Save** to save the configuration. On the **Dashboard** tab page of Yarn, choose **More** > **Restart Service**, verify the identity, and click **OK**. After the service is restarted, go to **Step 1.3**.
3. Choose **Cluster** > **Services** and check whether the Yarn service status is normal.

Step 2 Log in to the active management node as user **omm**.

Step 3 Switch the scheduler.

The following switching modes are available:

0: converts the Capacity scheduler configurations into the Superior scheduler configurations and then switches the Capacity scheduler to the Superior scheduler.

1: converts the Capacity scheduler configurations into the Superior scheduler configurations only.

2: switches the Capacity scheduler to the Superior scheduler only.

- Mode **0** is recommended if the cluster environment is simple and the number of tenants is less than 20.

  Run the following command:

  sh ${BIGDATA_HOME}/om-server/om/sbin/switchScheduler.sh -c *Cluster ID* **-m 0**

  NOTE

  You can choose **Cluster** > **Cluster Properties** on FusionInsight Manager to view the cluster ID.

  ```
  Start to convert Capacity scheduler to Superior Scheduler, clusterId=1
  Start to convert Capacity scheduler configurations to Superior. Please wait...
  Convert configurations successfully.
  Start to switch the Yarn scheduler to Superior. Please wait...
  Switch the Yarn scheduler to Superior successfully.
  ```

- If the cluster environment or tenant information is complex and you need to retain the queue configurations of the Capacity scheduler on the Superior scheduler, it is recommended that you use mode **1** first to convert the Capacity scheduler configurations, check the converted configurations, and then use mode **2** to switch the Capacity scheduler to the Superior scheduler.

  a. Run the following command to convert the Capacity scheduler configurations into the Superior scheduler configurations:

     sh ${BIGDATA_HOME}/om-server/om/sbin/switchScheduler.sh -c *Cluster ID* **-m 1**

     ```
     Start to convert Capacity scheduler to Superior Scheduler, clusterId=1
     Start to convert Capacity scheduler configurations to Superior. Please wait...
     Convert configurations successfully.
     ```

  b. Run the following command to switch the Capacity scheduler to the Superior scheduler:

     sh ${BIGDATA_HOME}/om-server/om/sbin/switchScheduler.sh -c *Cluster ID* **-m 2**

     ```
     Start to convert Capacity scheduler to Superior Scheduler, clusterId=1
     Start to switch the Yarn scheduler to Superior. Please wait...
     Switch the Yarn scheduler to Superior successfully.
     ```

- If you do not need to retain the queue configurations of the Capacity scheduler, use mode **2**.

  a. Log in to FusionInsight Manager and delete all tenants except the default tenant.

  b. On FusionInsight Manager, delete all resource pools except the default resource pool.

     Run the following command to switch the Capacity scheduler to the Superior scheduler:

     sh ${BIGDATA_HOME}/om-server/om/sbin/switchScheduler.sh -c *Cluster ID* **-m 2**

     ```
     Start to convert Capacity scheduler to Superior Scheduler, clusterId=1
     Start to switch the Yarn scheduler to Superior. Please wait...
     Switch the Yarn scheduler to Superior successfully.
     ```

NOTE

You can query the scheduler switching logs on the active management node.

- ${BIGDATA_LOG_HOME}/controller/aos/switch_scheduler.log
- ${BIGDATA_LOG_HOME}/controller/aos/aos.log

----End

10.8 System Configuration

10.8.1 Configuring Permissions

10.8.1.1 Managing Users

10.8.1.1.1 Creating a User

Scenario

FusionInsight Manager supports a maximum of 50,000 users (including built-in users). By default, only user **admin** has the highest operation permissions of FusionInsight Manager. You need to create users on FusionInsight Manager and assign operation permissions to the users based on service requirements.

NOTE

Information about the newly created user is synchronized to the OS caches of all nodes in the cluster. The value of **uid** of the new user ranges from **20000** to **100000**. You can run the **id** *Username* command on the node to check the value.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **User**.

Step 3 On the **User** page, click **Create**.

Step 4 Set **Username**. The username can contain digits, letters, underscores (_), hyphens (-), and spaces. It is case-insensitive and cannot be the same as any existing username in the system or OS.

Step 5 Set **User Type** to **Human-Machine** or **Machine-Machine**.

- **Human-Machine** user: used for FusionInsight Manager O&M and component client operations. If you select this option, you also need to set **Password** and **Confirm Password**.
- **Machine-Machine** user: used for component application development. If you select this option, the password is randomly generated.

Step 6 In the **User Group** area, click **Add** to add one or more user groups to the list.

NOTE

- If the selected user group has been bound to a role or a permission policy has been configured in Ranger, the user can obtain the corresponding permissions.
- After FusionInsight Manager is installed, some user groups generated by default have special permissions. Select desired user groups based on the descriptions on the UI.
- If existing user groups cannot meet your requirements, click **Create User Group** to create a user group. For details, see **Creating a User Group**.

Step 7 Select a group from the **Primary Group** drop-down list to create directories and files.

The drop-down list contains all groups selected in **User Group**.

NOTE

A user can belong to multiple groups (including the primary group and secondary groups). The primary group is set to facilitate maintenance and comply with the permission mechanism of the Hadoop community. The primary group has the same permission control functionality as other groups.

Step 8 In the **Role** area, click **Add** to bind roles to the user.

NOTE

- Adding a role when you create a user can specify the user permissions.
- If the permissions granted to the user from the user group cannot meet service requirements, you can bind other created roles to the user. You can also click **Create Role** to create a role first. For details, see **Creating a Role**.

  It takes 3 minutes to make role permission assignment to the user take effect. If the permissions obtained from the user group are enough, you do not need to add a role.
- After Ranger authentication is enabled for a component, you need to configure Ranger policies to assign permissions to the user except the permissions of default user group or role.
- If a user is not added to a user group or assigned a role, the user cannot view information or perform operations after logging in to FusionInsight Manager.

Step 9 Enter information in **Description**.

Step 10 Click **OK**.

After a human-machine user is created, you need to change the initial password as prompted after logging in to FusionInsight Manager.

----End

10.8.1.1.2 Modifying User Information

Scenario

You can modify user information on FusionInsight Manager, including the user group, primary group, role permission assignment, and user description.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **User**.

Step 3 Locate the row that contains the target user and click **Modify** in the **Operation** column.

Modify the parameters based on service requirements.

NOTE

It takes three minutes at most for the change of the user group or role permissions to take effect.

Step 4 Click **OK**.

----End

10.8.1.1.3 Exporting User Information

Scenario

You can export information about all created users on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **User**.

Step 3 Click **Export All** to export all user information at a time.

The exported user information contains the username, creation time, description, user type, primary group, user group list, roles bound to the user, and bound password policy.

Step 4 Set **Save AS** to **TXT** or **CSV**. Click **OK**.

----End

10.8.1.1.4 Locking a User

Scenario

A user may be suspended for a long period of time due to service changes. For security purposes, you can lock such a user.

You can lock a user in using either of the following methods:

- Automatic locking: You can set **Password Retries** in the password policy to automatically lock the user whose login attempts exceed this parameter value. For details, see **Configuring Password Policies**.
- Manual locking: You manually lock a user.

This section describes how to lock a user manually. Machine-machine users cannot be locked.

Impact on the System

A locked user cannot log in to FusionInsight Manager or perform identity authentication in the cluster. A locked user can be used only after being manually unlocked or the lock time expires.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **User**.

Step 3 Locate the row that contains the target user and click **Lock** in the **Operation** column.

Step 4 In the window that is displayed, select **I have read the information and understand the impact**. Click **OK**.

----End

10.8.1.1.5 Unlocking a User

Scenario

You can unlock a user on FusionInsight Manager if the user has been locked because the number of login attempts exceeds the threshold. Only users created on FusionInsight Manager can be unlocked.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **User**.

Step 3 Locate the row that contains the target user and click **Unlock** in the **Operation** column.

Step 4 In the window that is displayed, select **I have read the information and understand the impact**. Click **OK**.

----End

10.8.1.1.6 Deleting a User

Scenario

Based on service requirements, you can delete system users that are no longer used on FusionInsight Manager.

NOTE

- After a user is deleted, the provisioned ticket granting ticket (TGT) is still valid within 24 hours. The user can use the TGT for security authentication and access the system.
- If a new user has the same name as the deleted user, the new user will inherit all owner permissions of the deleted user. You are advised to determine whether to delete the resources owned by the deleted user based on service requirements, for example, files in HDFS.
- The default user **admin** cannot be deleted.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **User**.

Step 3 Locate the row that contains the target user, click **More**, and select **Delete**.

NOTE

To delete users in batches, select the users at a time and click **Delete**.

Step 4 In the displayed dialog box, click **OK**.

----End

10.8.1.1.7 Changing a User Password

Scenario

For security purposes, the password of a human-machine user must be changed periodically.

If users have the permission to use FusionInsight Manager, they can change their passwords on FusionInsight Manager.

If users do not have the permission to use FusionInsight Manager, they can change their passwords on the client.

Prerequisites

- You have obtained the current password policy.
- The user has installed the client on any node in the cluster and obtained the IP address of the node. The password of the client installation user can be obtained from the administrator.

Changing the Password on FusionInsight Manager

Step 1 Log in to FusionInsight Manager.

Step 2 Move the cursor to the username in the upper right corner of the page.

On the user account drop-down menu, choose **Change Password**.

Step 3 On the displayed page, set **Current Password**, **New Password**, and **Confirm Password**, and click **OK**.

By default, the password must meet the following complexity requirements:

- The password contains at least 8 characters.
- The password must contain at least four types of the following characters: uppercase letters, lowercase letters, digits, spaces, and special characters (`~!@#$%^&*()-_=+|[{}];',<.>/\?).
- The password cannot be the same as the username or the username spelled backwards.
- The password cannot be a common easily-cracked password.
- The password cannot be the same as the password used in the latest *N* times. *N* indicates the value of **Repetition Rule** configured in **Configuring Password Policies**.

----End

Changing the Password on the Client

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to switch to the client directory, for example, **/opt/client**:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Change the user password. This operation takes effect for all servers.

kpasswd *System username*

For example, if you want to change the password of system user **test1**, run the **kpasswd test1** command.

By default, the password must meet the following complexity requirements:

- The password contains at least 8 characters.
- The password must contain at least four types of the following characters: uppercase letters, lowercase letters, digits, spaces, and special characters (`~!@#$%^&*()-_=+|[{}];',<.>/\?).
- The password cannot be the same as the username or the username spelled backwards.
- The password cannot be a common easily-cracked password.
- The password cannot be the same as the password used in the latest *N* times. *N* indicates the value of **Repetition Rule** configured in **Configuring Password Policies**.

NOTE

If an error occurs during the running of the **kpasswd** command, try the following operations:

- Stop the SSH session and start it again.
- Run the **kdestroy** command and then run the **kpasswd** command again.

----End

10.8.1.1.8 Initializing a Password

Scenario

If a user forgets the password or the public account password needs to be changed periodically, you can initialize the password on FusionInsight Manager. After the password is initialized, the system user needs to change the password upon first login.

NOTE

This operation applies only to human-machine users.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **User**.

Step 3 Locate the row that contains the target user, click **More**, and select **Initialize Password**. In the displayed dialog box, enter the password of the current login user and click **OK**. In the **Initialize Password** dialog box, click **OK**.

Step 4 Set **New Password** and **Confirm Password**, and click **OK**.

The password must meet the following complexity requirements by default:

- Contains at least 8 characters.
- Contains at least four types of the following: uppercase letters, lowercase letters, numbers, spaces, and special characters (`~!@#$%^&*()-_=+|[{}];',<.>/\?).
- Cannot be the same as the username or the username spelled backwards.
- Cannot be a common easily-cracked password.
- Cannot be the same as the password used in the latest *N* times. *N* indicates the value of **Repetition Rule** configured in **Configuring Password Policies**.

----End

10.8.1.1.9 Exporting an Authentication Credential File

Scenario

If a user uses a security mode cluster to develop applications, the keytab file of the user needs to be obtained for security authentication. You can export keytab files on FusionInsight Manager.

NOTE

After a user password is changed, the exported keytab file becomes invalid, and you need to export a keytab file again.

Prerequisites

Before downloading the keytab file of a Human-Machine user, the password of the user must be changed at least once on the Manager portal or a client;

otherwise, the downloaded keytab file cannot be used For details, see **Changing a User Password**.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **User**.

Step 3 Locate the row that contains the user whose keytab file needs to be exported, choose **More** > **Download Authentication Credential**, specify the save path after the file is automatically generated, and keep the file properly.

The authentication credential includes the **krb5.conf** file of the Kerberos service.

After the authentication credential file is decompressed, you can obtain the following two files:

- The **krb5.conf** file contains the authentication service connection information.
- The **user.keytab** file contains user authentication information.

----End

10.8.1.2 Managing User Groups

Scenario

FusionInsight Manager supports a maximum of 5000 user groups (including built-in user groups). You can create and manage different user groups based on service scenarios on FusionInsight Manager. A user group is bound to a role to obtain operation permissions. After a user is added to a user group, the user can obtain the operation permissions of the user group. A user group can be used to classify users and manage multiple users.

NOTE

Information about the newly created user group is synchronized to the OS cache of all nodes in the cluster. The value range of **gid** for the newly created user group is 8000–8999, 9998, and 10000–300000.

Prerequisites

- You have learned service requirements and created roles required by service scenarios.
- You have logged in to FusionInsight Manager.

Creating a User Group

Step 1 Choose **System** > **Permission** > **User Group**.

Step 2 Above the user group list, click **Create User Group**.

Step 3 Set **Group Name** and **Description**.

The group name contains 1 to 64 characters, including case-insensitive letters, digits, underscores (_), hyphens (-), and spaces. It cannot be the same as an existing user group name in the system.

Step 4 In the **Role** area, click **Add** to select a role and add it.

NOTE

- For components (except HDFS and Yarn) for which Ranger authorization has been enabled, the permissions of non-default roles on Manager do not take effect. You need to configure Ranger policies to assign permissions to user groups.
- If the resource requests of HDFS and Yarn are beyond the Ranger policies, the ACL rules of the components still take effect.

Step 5 In the **User** area, click **Add** to select a user and add it.

Step 6 Click **OK**.

The user group is created.

----End

Viewing User Group Information

By default, all user groups are displayed in the user group list. You can click the arrow on the left of a user group name to view details about the user group, including the user quantity, specific users, and bound roles of the user group.

Modifying Information About a User Group

Locate the row that contains the target user group, and click **Modify** to modify its information.

Exporting Information About a User Group

Click **Export All** to export all user group information at a time in **TXT** or **CSV** format.

The user group information contains the following fields: user group name, description, number of users, cluster, service, user list, and role list.

Deleting a User Group

Locate the row that contains the target user group, and click **Delete**. To delete multiple user groups in batches, select the target user groups and click **Delete** above the user group list. A user group that contains users cannot be deleted. To delete such a user group, delete all its users by modifying the user group first.

10.8.1.3 Managing Roles

Scenario

FusionInsight Manager supports a maximum of 5000 roles (including system built-in roles but excluding roles automatically created by tenants). Based on different service requirements, you need to create and manage different roles on FusionInsight Manager and perform authorization management for FusionInsight Manager and components using roles.

Prerequisites

- You have learned service requirements.
- You have logged in to FusionInsight Manager.

Creating a Role

Step 1 Choose **System** > **Permission** > **Role**.

Step 2 On the displayed page, click **Create Role** and specify **Role Name** and **Description**.

The role name consists of 3 to 50 characters, including digits, letters, and underscores (_). It cannot be the same as an existing role name in the system. The role name cannot start with **Manager**, **System**, or **default**. For example, the role name cannot be **Manager_test**.

Step 3 In the **Configure Resource Permission** area, click the cluster whose permissions are to be added and select service permissions for the role.

When setting permissions for a component, enter a resource name in the search text box in the upper right corner and click the search icon to view the search result.

The search result contains only directories, but not subdirectories. Search by keyword supports fuzzy match and is case-insensitive.

NOTE

- For components (except HDFS and Yarn) for which Ranger authorization has been enabled, the permissions of non-default roles on Manager do not take effect. You need to configure Ranger policies to assign permissions to user groups.
- If the resource requests of HDFS and Yarn are beyond the Ranger policies, the ACL rules of the components still take effect.
- A maximum of 1000 permissions can be set for a component at a time.

Step 4 Click **OK**.

----End

Modifying Role Information

Locate the row that contains the target role and click **Modify**.

Exporting Role Information

Click **Export All** to export all role information at a time in **TXT** or **CSV** format.

The role information contains the following fields: role name, description, creation time, user, and user group.

Deleting a Role

Locate the row that contains the target role and click **Delete**. To delete multiple roles in batches, select the target roles and click **Delete** above the role list. A role bound to a user cannot be deleted. To delete such a role, disassociate the role from the user by modifying the user first.

Task Example (Creating a Manager Role)

Step 1 Choose **System** > **Permission** > **Role**.

Step 2 On the displayed page, click **Create Role** and fill in **Role Name** and **Description**.

Step 3 In the **Configure Resource Permission** area, click **Manager** and set permissions for the role.

Manager permissions:

- Cluster
  - **view** permission: permission to view information on the **Cluster** page and view alarms and events under **O&M** > **Alarm**.
  - **management** permission: permission for management on the **Cluster** and **O&M** pages.
- User
  - **view** permission: permission to view information on pages under **System** > **Permission**.
  - **management** permission: permission for management on pages under **System** > **Permission**.
- Audit

  management permission: permission for management on the **Audit** page.
- Tenant

  management permission: permission for management on the **Tenant** page and permission to view alarms and events under **O&M** > **Alarm**.
- System

  management permission: permission for management on all pages except those under **Permission** on the **System** page and permission to view alarms and events under **O&M** > **Alarm**.

Step 4 Click **OK**.

----End

10.8.1.4 Security Policies

10.8.1.4.1 Configuring Password Policies

Scenario

To keep up with service security requirements, you can set password security rules, user login security rules, and user locking rules on FusionInsight Manager.

NOTICE

- Modify password policies based on service security requirements, because they involve user management security. Otherwise, security risks may be incurred.
- Change the user password after modifying the password policy, and then the new password policy can take effect.
- This password policy applies to human-machine accounts created on Manager.

Adding a Password Policy

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **Security Policy** > **Password Policy**.

Step 3 Click **Add Password Policy** and modify the password policy as prompted.

For details about the parameters, see **Table 10-44**.

Table 10-44 Password policy parameters

Parameter	Description
Password Policy Name	The value is a string of 3 to 32 characters, including case-insensitive letters, digits, underscores (_), and hyphens (-). It cannot start with a hyphen (-).
Minimum Password Length	Indicates the minimum number of characters a password contains. The value ranges from **8** to **32**.
Character Types	Indicates how many character types in the following types a password can contain at least: uppercase letters, lowercase letters, digits, spaces, and special characters (~`!?,.:;-_'(){}[]/<>@#$%^&*+|\=). The value can be **4** or **5**. The default value is **4**, which means that a password can contain uppercase letters, lowercase letters, digits, and special characters. If you set the parameter to **5**, a password can contain all the five character types mentioned above.
Password Retries	Indicates the number of consecutive wrong password attempts allowed before the system locks the user. The value ranges from **3** to **30**.
User Lock Duration (Min)	Indicates the time period in which a user is locked when the user lockout conditions are met. The value ranges from **5** to **120**.
Password Validity Period (Day)	Indicates the validity period of a password. The value ranges from **0** to **90**. **0** indicates that the password is permanently valid.

Parameter	Description
Repetition Rule	Indicates the number of previous passwords that cannot be reused when you change the password. The value ranges from **1** to **5**. The default value is **1**. This policy applies to only human-machine accounts.
Password Expiration Notification (Days)	Indicates the number of days in advance users are notified that their passwords are about to expire. After the value is set, if the difference between the cluster time and the password expiration time is smaller than this value, the user receives password expiration notifications. When logging in to FusionInsight Manager, the user will be notified that the password is about to expire and a message is displayed asking the user to change the password. The value ranges from **0** to *X* (*X* must be set to the half of the password validity period and rounded down). Value **0** indicates that no notification is sent.
Interval for Deleting Authentication Failure Records (Min)	Indicates the interval of retaining incorrect password attempts. The value ranges from **0** to **1440**. **0** indicates that incorrect password attempts are permanently retained, and **1440** indicates that incorrect password attempts are retained for one day.

Step 4 Click **OK** to save the configurations.

A new user uses the default password policy. After a new password policy is created, you can manually select the password policy when creating a user. You can modify the password policy of an existing user. For details, see **Modifying User Information**.

----End

NOTE

A maximum of 32 password policies can be created.

Modifying a Password Policy

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **Security Policy** > **Password Policy**.

Step 3 Click **Modify** in the row that contains the target password policy. On the **Modify Password Policy** page, modify the password policy as prompted.

For details about the parameters, see **Table 10-44**.

Step 4 Click **OK** to save the configurations.

----End

NOTE

- Users (except **admin**) cannot modify their own password policies.
- After the password policy bound to a user is modified, if the remaining password validity period is greater than the password validity period in the new password policy, the password validity period is set to the validity period in the new password policy. If the remaining password validity period is less than the password validity period in the new password policy, the password validity period remains unchanged.

Deleting a Password Policy

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **Security Policy** > **Password Policy**.

Step 3 Click **Delete** in the row that contains the target password policy. In the dialog box that is displayed, click **OK**.

----End

NOTE

The default password policy and the password policy that has been bound to a user cannot be deleted.

10.8.1.4.2 Configuring the Independent Attribute

Scenario

User **admin** or administrators who are bound to the Manager_administrator role can configure the independent attribute on FusionInsight Manager so that common users (all service users in the cluster) can set or cancel their own independent attributes.

After the independent attribute option is toggled on, service users need to log in to the system and set the independent attribute.

Constraints

- Administrators cannot set or cancel the independent attribute of a user.
- Administrators cannot obtain the authentication credentials of independent users.

Prerequisites

You have obtained the required administrator username and password.

Procedure

Toggling On or Off the Independent Attribute

Step 1 Log in to FusionInsight Manager as user **admin** or a user bound to the Manager_administrator role.

Step 2 Choose **System** > **Permission** > **Security Policy** > **Independent Configurations**.

Step 3 Toggle on or off **Independent Attribute**, enter the password as prompted, and click **OK**.

Step 4 After the identity is authenticated, wait until the OMS configuration is modified and click **Finish**.

NOTE

After the independent attribute is disabled:

- A user who has the attribute can cancel it from the drop-down list of the username in the upper right corner of the page. The user cannot set the independent attribute again once it is cancelled. After the attribute is cancelled, existing independent tables will retain the attribute. However, the user cannot create independent tables again.
- Users without this attribute cannot set or cancel the attribute.

Configuring the Independent Attribute

Step 5 Log in to FusionInsight Manager as a service user.

NOTICE

Administrators cannot initialize the password of the user after the independent attribute is set. If the user password is forgotten, the password cannot be retrieved.

User **admin** cannot set the independent attribute.

Step 6 Move the cursor to the username in the upper right corner of the page.

Step 7 Select **Set Independent** or **Cancel Independent**.

NOTE

- If the independent attribute is toggled on and has been set for the service user, **Cancel Independent** is displayed.
- If the independent attribute is toggled on but has been cancelled for the service user, **Set Independent** is displayed.
- If the independent attribute is toggled off but has been set for the service user, **Cancel Independent** is displayed.
- If the independent attribute is toggled off and has been cancelled for the service user, no option related to the independent attribute is displayed.

Step 8 Enter the password as prompted and click **OK**.

Step 9 After the identity is authenticated, click **OK** in the dialog box.

----End

10.8.2 Configuring Interconnections

10.8.2.1 Configuring SNMP Northbound Parameters

Scenario

If users need to view alarms of a cluster on the O&M platform, you can use Simple Network Management Protocol (SNMP) on FusionInsight Manager to report related data to the network management system (NMS).

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Interconnection** > **SNMP**.

Step 3 Toggle on **SNMP Service**.

The SNMP service is disabled by default. indicates that the service is enabled.

Step 4 Set interconnection parameters according to **Table 10-45**.

Table 10-45 Interconnection parameters

Parameter	Description
Version	Specifies the version of SNMP, which can be: • **V2C**: This is an earlier version with low security. • **V3**: This is a later version with higher security than SNMP V2C. SNMP V3 is recommended.
Local Port	Specifies the local port. The default value is **20000**. The value ranges from **1025** to **65535**.
Read Community Name	Specifies the read-only community name. This parameter is available only when **Version** is set to **V2C**.
Write Community Name	Specifies the write community name. This parameter is available only when **Version** is set to **V2C**.
Security Username	Specifies the SNMP security username. This parameter is available only when **Version** is set to **V3**.
Authentication Protocol	Specifies the authentication protocol. This parameter is available only when **Version** is set to **V3**. SHA is recommended.
Authentication Password	Specifies the authentication password. This parameter is available only when **Version** is set to **V3**.

Parameter	Description
Confirm Password	Used to confirm the authentication password. This parameter is available only when **Version** is set to **V3**.
Encryption Protocol	Specifies the encryption protocol. This parameter is available only when **Version** is set to **V3**. AES256 is recommended.
Encryption Password	Specifies the encryption password. This parameter is available only when **Version** is set to **V3**.
Confirm Password	Used to confirm the encryption password. This parameter is available only when **Version** is set to **V3**.

NOTE

- The value of **Security Username** cannot contain repeated strings with the unit length as a common factor of 64 (such as 1, 2, 4, and 8), for example, **abab** and **abcdabcd**.
- The **Authentication Password** and **Encryption Password** must contain 8 to 16 characters, including at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters. The two passwords must be different. The two passwords cannot be the same as the security username or the reverse of the security username.
- For security purposes, periodically change the authentication password and encryption password when the SNMP protocol is used.
- If SNMP v3 is used, a security user will be locked after five consecutive authentication failures within 5 minutes. The user will be automatically unlocked 5 minutes later.

Step 5 Click **Create Trap Target** in the **Trap Target** area. In the displayed dialog box, set the following parameters:

- **Target Symbol**: specifies the trap target ID, which is the ID of the NMS or host that receives traps. The value consists of 1 to 255 characters, including letters or digits.
- **Target IP Address Mode**: specifies the mode of the target IP address. The value can be **IPv4** or **IPv6**.
- **Target IP Address**: specifies the target IP address, which can communicate with the management plane IP address of the management node.
- **Target Port**: specifies the port receiving traps. The port number must be consistent with the peer end and ranges from 0 to 65535.
- **Trap Community Name**: This parameter is available only when **Version** is set to **V2C** and is used to report the community name.

Click **OK**.

The **Create Trap Target** dialog box is closed.

Step 6 Click **OK**.

----End

10.8.2.2 Configuring Syslog Northbound Parameters

Scenario

If users need to view alarms and events of a cluster on the unified alarm reporting platform, you can use the Syslog protocol on FusionInsight Manager to report related data to the alarm platform.

NOTICE

If the Syslog protocol is not encrypted, data may be stolen.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Interconnection** > **Syslog**.

Step 3 Toggle on **Syslog Service**.

The Syslog service is disabled by default. indicates that the service is enabled.

Step 4 Set northbound parameters according to **Table 10-46**.

Table 10-46 Syslog interconnection parameters

Parameter Area	Parameter	Description
Syslog Protocol	Server IP Address Mode	Specifies the IP address mode of the interconnected server. The value can be **IPV4** or **IPV6**.
	Server IP Address	Specifies the IP address of the interconnected server.
	Server Port	Specifies the port number for interconnection.
	Protocol	Specifies the protocol type. The options are as follows: • **TCP** • **UDP**

Parameter Area	Parameter	Description
	Severity Level	Specifies the severity of the reported message. The options are as follows: • **Emergency** • **Alert** • **Critical** • **Error** • **Warning** • **Notice** • **Informational** (default value) • **Debug** **NOTE** **Severity Level** and **Facility** determine the priority of the sent message. **Priority** = **Facility** × 8 + **Severity Level** For details about the values of **Severity Level** and **Facility**, see **Table 10-47**.
	Facility	Specifies the module where the log is generated. For details about the available values of this parameter, see **Table 10-47**. Default value **local use 0 (local0)** is recommended.
	Identifier	Specifies the product ID. The default value is **FusionInsight Manager**. The identifier can contain a maximum of 256 characters, including letters, digits, underscores (_), periods (.), hyphens (-), spaces, and the following special characters: | $ { }
Report Message	Report Format	Specifies the message format of the alarm report. For details, see the help information on the page. The report format can contain a maximum of 1024 characters, including letters, digits, underscores (_), periods (.), hyphens (-), spaces, and the following special characters: | $ { } **NOTE** For details about each field in the report format, see **Table 10-48**.
	Alarm Type	Specifies the type of the alarm to be reported.
	Alarm Severities	Specifies the level of the alarm to be reported.

Parameter Area	Parameter	Description
Uncleared Alarm Reporting	Periodic Uncleared Alarm Reporting	Specifies whether to report uncleared alarms in a specified period. You can toggle on or off the function. The function is toggled off by default.
	Report Interval (min)	Specifies the interval for periodically reporting uncleared alarms. This parameter is valid only when **Periodic Uncleared Alarm Reporting** is enabled. The default value is **15**, in minutes. The value ranges from **5** to **1440** (one day).
Heartbeat Settings	Heartbeat Reporting	Specifies whether to periodically report Syslog heartbeat messages. You can toggle on or off the function. The function is toggled off by default.
	Heartbeat Interval (minutes)	Specifies the interval for periodically reporting heartbeat messages. This parameter is valid only when **Heartbeat Reporting** is enabled. The default value is **15**, in minutes. The value ranges from **1** to **60**.
	Heartbeat Packet	Specifies the heartbeat message to be reported. This parameter is valid when **Heartbeat Reporting** is toggled on and cannot be left blank. The value can contain a maximum of 256 characters, including digits, letters, underscores (_), vertical bars (|), colons (:), spaces, commas (,), and periods (.).

NOTE

After the periodic heartbeat packet function is enabled, packets may be interrupted during automatic recovery of some cluster error tolerance (for example, active/standby OMS switchover). In this case, wait for automatic recovery.

Step 5 Click **OK**.

----End

Related Information

Table 10-47 Numeric codes of **Severity Level** and **Facility**

Severity Level	Facility	Numeric Code
Emergency	kernel messages	0
Alert	user-level messages	1
Critical	mail system	2

-	clock daemon (note 2)	15
-	local use 0~7 (local0 ~ local7)	16 to 23

Table 10-48 Report format information fields

Information Field	Description
dn	Cluster name
id	Alarm ID
name	Alam name
serialNo	Alarm serial number **NOTE** The serial numbers of the fault alarms and the corresponding clear alarms are the same.
category	Alarm type. The options are as follows: ● **0**: fault alarm ● **1**: clear alarm ● **2**: event
occurTime	Time when the alarm was generated
clearTime	Time when this alarm was cleared

Information Field	Description
isAutoClear	Whether an alarm is automatically cleared. The options are as follows: • **1**: yes • **0**: no
locationInfo	Location where the alarm was generated
clearType	Alarm clearance type. The options are as follows: • **-1**: not cleared • **0**: automatically cleared • **2**: manually cleared
level	Severity. The options are as follows: • **1**: critical alarm • **2**: major alarm • **3**: minor alarm • **4**: warning alarm
cause	Alarm cause
additionalInfo	Additional information
object	Alarm object

10.8.2.3 Configuring Monitoring Metric Dumping

Scenario

The monitoring data reporting function writes the monitoring data collected in the system into a text file and uploads the file to a specified server in FTP or SFTP mode.

Before using this function, you need to perform related configurations on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Interconnection** > **Upload Performance Data**.

Step 3 Toggle on **Upload Performance Data**.

The performance data upload service is disabled by default. indicates that the service is enabled.

Step 4 Set the upload parameters according to **Table 10-49**.

Table 10-49 Upload parameters

Parameter	Description
FTP IP Address Mode	Specifies the server IP address mode. This parameter is mandatory. The value can be **IPV4** or **IPV6**.
FTP IP Address	Specifies the IP address of the FTP server for storing monitoring files after the monitoring metric data is interconnected. This parameter is mandatory.
FTP Port	Specifies the port for connecting to the FTP server. This parameter is mandatory.
FTP Username	Specifies the username for logging in to the FTP server. This parameter is mandatory.
FTP Password	Specifies the password for logging in to the FTP server. This parameter is mandatory.
Save Path	Specifies the path for storing monitoring files on the FTP server. This parameter is mandatory.
Dump Interval (second)	Specifies the interval at which monitoring files are periodically stored on the FTP server, in seconds. This parameter is mandatory.
Dump Mode	Specifies the protocol used for sending monitoring files. This parameter is mandatory. The value can be **SFTP** or **FTP**. You are advised to use the SFTP mode based on SSH v2. Otherwise, security risks may be incurred.
SFTP Service Public Key	Specifies the public key of the FTP server. This parameter is optional. It is valid only when **Dump Mode** is set to **SFTP**.

Step 5 Click **OK**.

NOTE

If the dump mode is SFTP and the public key of the SFTP service is empty, the system displays a security risk warning. You need to evaluate the security risk and then save the configuration.

----End

Data Format

After the configuration is complete, the monitoring data reporting function periodically writes monitoring data in the cluster to text files and reports the files to the corresponding FTP/SFTP service based on the configured reporting period.

- Principles for generating monitoring files
  - The monitoring metrics are written to files generated every 30, 60, and 300 seconds based on the metric collection period.

    30s: real-time metrics that are collected every 30s by default

    60s: real-time metrics that are collected every 60s by default

300s: all metrics that are not collected every 30s or 60s

- File name format: *metric_{Interval}_{File creation time YYYYMMDDHHMMSS}.log*

  Example: **metric_60_20160908085915.log**

  metric_300_20160908085613.log

- Monitoring file content
  - Format of monitoring files:

    "Cluster ID|Cluster name|Displayed name|Service name|Metric ID|Collection time|Collection host@m@Sub-metric|Unit|Metric value", where fields are separated using vertical bars (|). For example:

    ```
    1|xx1|Host|Host|10000413|2019/06/18 10:05:00|189-66-254-146|KB/s|309.910
    1|xx1|Host|Host|10000413|2019/06/18 10:05:00|189-66-254-152|KB/s|72.870
    2|xx2|Host|Host|10000413|2019/06/18 10:05:00|189-66-254-163|KB/s|100.650
    ```

    Note: The actual files are not in that format.

  - Interval for uploading monitoring files:

    The interval for uploading monitoring files can be set using the **Dump Interval (second)** parameter on the page. Currently, the interval can range from **30** to **300**. After the configuration is complete, the system periodically uploads files to the corresponding FTP/SFTP server at the specified interval.

- Monitoring metric description file
  - Metric set file

    The metric set file **all-shown-metric-zh_CN** contains detailed information about all metrics. After obtaining the metric IDs from the files reported by the third-party system, you can query details about the metrics from the metric set file.

    Location of the metric set file:

    Active and standby OMS nodes: {*FusionInsight installation path*} **/om-server/om/etc/om/all-shown-metric-zh_CN**

    Content of the metric set file:

    ```
    Real-Time Metric ID,5-Minute Metric ID,Metric Name,Metric Collection Period (s),Collected by Default,Service Belonged To,Role Belonged To
    00101,10000101,JobHistoryServer non-heap memory usage,30,false,Mapreduce,JobHistoryServer
    00102,10000102,JobHistoryServer non-heap memory allocation volume,30,false,Mapreduce,JobHistoryServer
    00103,10000103,JobHistoryServer heap memory usage,30,false,Mapreduce,JobHistoryServer
    00104,10000104,JobHistoryServer heap memory allocation volume,30,false,Mapreduce,JobHistoryServer
    00105,10000105,Number of blocked threads,30,false,Mapreduce,JobHistoryServer
    00106,10000106,Number of running threads,30,false,Mapreduce,JobHistoryServer
    00107,10000107,GC time,30,false,Mapreduce,JobHistoryServer
    00110,10000110,JobHistoryServer CPU usage,30,false,Mapreduce,JobHistoryServer
    ...
    ```

  - Field description of critical metrics

    Real-Time Metric ID: indicates the ID of the metric whose collection period is 30s or 60s.

    5-Minute Metric ID: indicates the ID of a 5-minute (300s) metric.

    Metric Collection Period (s): indicates the collection period of real-time metrics. The value can be **30** or **60**.

    Service Belonged To: indicates the name of the service to which a metric belongs, for example, HDFS and HBase.

Role Belonged To: indicates the name of the role to which a metric belongs, for example, JobServer and RegionServer.

– Description

For metrics whose collection period is 30s/60s, you can find the corresponding metric description by referring to the first column, that is, **Real-Time Metric ID**.

For metrics whose collection period is 300s, you can find the corresponding metric description by referring to the second column, that is, **5-Minute Metric ID**.

10.8.3 Importing a Certificate

Scenario

CA certificates are used to encrypt data during communication between FusionInsight Manager modules and between cluster component clients and servers to ensure security. CA certificates can be quickly imported to FusionInsight Manager for product security. Import CA certificates in following scenarios:

- When the cluster is installed for the first time, you need to replace the enterprise certificate.
- If the enterprise certificate has expired or security hardening is required, you need to replace it with a new certificate.

Impact on the System

- During certificate replacement, the cluster needs to be restarted. In this case, the system becomes inaccessible and cannot provide services.
- After the certificate is replaced, the certificates used by all components and FusionInsight Manager modules are automatically updated.
- After the certificate is replaced, you need to reinstall the certificate in the local environment where the certificate is not trusted.

Prerequisites

- You have generated the certificate file and key file or obtained them from the enterprise certificate administrator.
- You have obtained the files to be imported to the cluster, including the CA certificate file (***.crt**), key file (***.key**), and file that saves the key file password (**password.property**). The certificate name and key name can contain uppercase letters, lowercase letters, and digits. After the preceding files are generated, compress them into a TAR package.
- You have obtained a password for accessing the key file, for example, **Userpwd@123**.

  To avoid potential security risks, the password must meet the following complexity requirements:

  – It must contain at least eight characters.

  – It must contain at least four of the following character types: uppercase letters, lowercase letters, digits, and special characters ~`!?,.:;-_'(){}[]/<>@#$%^&*+|\=.

- When applying for certificates from the certificate administrator, you have provided the password for accessing the key file and applied for the certificate files in CRT, CER, CERT, and PEM formats and the key files in KEY and PEM formats. The requested certificates must have the issuing function.

Procedure

Step 1 Log in to FusionInsight Manager and choose **System** > **Certificate**.

Step 2 Click **Select File** on the right of **Upload Certificate**. In the file selection window, browse to select the obtained TAR package of the certificate files.

Step 3 Click **Upload**.

Manager uploads the compressed package and automatically imports the package.

Step 4 After the certificate is imported, the system displays a message asking you to synchronize the cluster configuration and restart the web service for the new certificate to take effect. Click **OK**.

Step 5 In the displayed dialog box, enter the password of the current login user and click **OK**. The cluster configuration is automatically synchronized and the web service is restarted.

NOTE

If the page is refreshed or the browser is closed during cluster configuration synchronization, perform the following operations to manually restart the web service:

1. Log in to the active OMS node as user **omm**.
2. Run the following command to restart HTTPD. **xxx** indicates the HTTPD version number. Replace it with the actual version number.

   sh ${BIGDATA_HOME}/om-server/Apache-httpd-*xxx*/setup/restarthttpd.sh
3. Run the following command to restart Tomcat:

   sh ${BIGDATA_HOME}/om-server/tomcat/bin/shutdown.sh;sh ${BIGDATA_HOME}/om-server/tomcat/bin/startup.sh
4. Run the following command to restart Knox:

   sh /opt/knox/bin/restart-knox.sh

Step 6 After the cluster is restarted, enter the URL for accessing FusionInsight Manager in the address box of the browser and check whether the FusionInsight Manager web page can be successfully displayed.

Step 7 Log in to FusionInsight Manager.

Step 8 In the upper right corner of **Homepage**, click **More** and select **Restart**.

Step 9 In the displayed dialog box, enter the password of the current login user and click **OK**.

----End

10.8.4 OMS Management

10.8.4.1 Overview of the OMS Page

Overview

Log in to FusionInsight Manager and choose **System** > **OMS**. You can perform maintenance operations on the OMS page, including viewing basic information, viewing the service status of OMS service modules, and manually triggering health checks.

NOTE

OMS is the management node of the O&M system. Generally, there are two OMS nodes that work in active/standby mode.

Basic Information

OMS-associated information is displayed on FusionInsight Manager, as listed in **Table 10-50**.

Table 10-50 OMS information

Item	Description
Version	Indicates the OMS version, which is consistent with the FusionInsight Manager version.
IP Mode	Indicates the IP address mode of the current cluster network.
HA Mode	Indicates the OMS working mode, which is specified by the configuration file during FusionInsight Manager installation.
Current Active	Indicates the host name of the active OMS node, that is, the host name of the active management node. Click a host name to go to the host details page.
Current Standby	Indicates the host name of the standby OMS node, that is, the host name of the standby management node. Click a host name to go to the host details page.
Duration	Indicates the duration for starting the OMS process.

OMS Service Status

FusionInsight Manager displays the running status of all OMS service modules. If the status of each service module is displayed as ●, the OMS is running properly.

Health Check

You can click **Health Check** on the OMS page to check the OMS status. If some check items are faulty, you can view the check description for troubleshooting.

Entering or Exiting Maintenance Mode

Configure OMS to enter or exit the maintenance mode.

System Parameters

Connect to the DMPS cluster in large-scale cluster scenarios.

10.8.4.2 Modifying OMS Service Configuration Parameters

Scenario

Based on the security requirements of the user environment, you can modify the Kerberos and LDAP configurations in the OMS on FusionInsight Manager.

Impact on the System

After the OMS service configuration parameters are modified, the corresponding OMS module needs to be restarted. In this case, FusionInsight Manager cannot be used.

Procedure

Modifying the okerberos configuration

Step 1 Log in to FusionInsight Manager and choose **System** > **OMS**.

Step 2 Locate the row that contains okerberos and click **Modify Configuration**.

Step 3 Modify the parameters according to **Table 10-51**.

Table 10-51 okerberos parameters

Parameter	Description
KDC Timeout (ms)	Timeout duration for an application to connect to Kerberos, in milliseconds. The value must be an integer.
Max Retries	Maximum number of retries for an application to connect to Kerberos, in seconds. The value must be an integer.
LDAP Timeout (ms)	Timeout duration for Kerberos to connect to LDAP, in milliseconds.
LDAP Search Timeout (ms)	Timeout duration for Kerberos to query user information in LDAP, in milliseconds.
Kadmin Listening Port	Port number of the Kadmin service.

Parameter	Description
KDC Listening Port	Port number of the kinit service.
Kpasswd Listening Port	Port number of the Kpasswd service.

Step 4 Click **OK**.

In the displayed dialog box, enter the password of the current login user and click **OK**. In the displayed confirmation dialog box, click **OK**.

Modifying the oldap configuration

Step 5 Locate the row that contains the oldap and click **Modify Configuration**.

Step 6 Modify the parameters according to **Table 10-52**.

Table 10-52 OLDAP parameters

Parameter	Description
LDAP Listening Port	Port number of the LDAP service.

Step 7 Click **OK**.

In the displayed dialog box, enter the password of the current login user and click **OK**. In the displayed confirmation dialog box, click **OK**.

NOTE

To reset the password of the LDAP account, you need to restart ACS. The procedure is as follows:

1. Log in to the active management node as user **omm** using PuTTY, and run the following command to update the domain configuration:

   sh ${BIGDATA_HOME}/om-server/om/sbin/restart-RealmConfig.sh

   The command is run successfully if the following information is displayed:

   Modify realm successfully. Use the new password to log into FusionInsight again.

2. Run the **sh $CONTROLLER_HOME/sbin/acs_cmd.sh stop** command to stop ACS.
3. Run the **sh $CONTROLLER_HOME/sbin/acs_cmd.sh start** command to start ACS.

Restarting the cluster

Step 8 Log in to FusionInsight Manager and restart the cluster by referring to **Performing a Rolling Restart of a Cluster**.

----End

10.8.5 Component Management

10.8.5.1 Viewing Component Packages

Scenario

A complete MRS cluster consists of multiple component packages. Before installing some services on FusionInsight Manager, check whether the component packages of those services have been installed.

Procedure

Step 1 Log in to FusionInsight Manager and choose **System** > **Component**.

Step 2 On the **Installed Component** page, view all components.

NOTE

In the **Platform Type** column, you can view the registered OS and platform type of the component.

Step 3 Click on the left of a component name to view the services and version numbers contained in the component.

----End

10.9 Cluster Management

10.9.1 Configuring Client

10.9.1.1 Installing a Client

Scenario

Install the clients of all services, except Flume, in the MRS cluster. MRS provides shell scripts for different services so that maintenance personnel can log in to related maintenance clients and implement maintenance operations.

NOTE

- Reinstall the client after server configuration is modified on FusionInsight Manager or after the system is upgraded. Otherwise, the versions of the client and server will be inconsistent.

Prerequisites

- A client installation directory will be automatically created if it does not exist. If the directory exists, it must be empty. The directory cannot contain any space.

- If a server outside the cluster is used as the client node, the node can communicate with the cluster service plane. Otherwise, client installation will fail.
- The client must have the NTP service enabled and synchronized time with the NTP server. Otherwise, client installation will fail.
- If clients of all components are downloaded, HDFS and MapReduce are installed in the same directory (*Client directory*/**HDFS/**).
- You can install and use the client as any user whose username and password have been obtained from the system administrator. This section uses **user_client** as an example. Ensure that user **user_client** is the owner of the server file directory (for example, **/opt/Bigdata/hadoopclient**) and client installation directory (for example, **/opt/client**). The permission for the two directories is **755**.
- You have obtained the component service username (a default user or new user) and password from the system administrator.
- When you install the client as a user other than **omm** or **root**, and the **/var/tmp/patch** directory already exists, you have changed the permission for the directory to **777** and changed the permission for the logs in the directory to **666**.

Procedure

Step 1 Obtain the required software packages.

Log in to FusionInsight Manager.

In the upper right corner of **Homepage**, click **Download Client**. The **Download Cluster Client** page is displayed.

NOTE

If you only need to install the client of a service in the cluster, choose **Cluster** > **Services**, click a service name, click **More**, and select **Download Client**. The **Download Client** page is displayed.

Step 2 Set **Select Client Type** to **Complete Client**.

Configuration Files Only is to download client configuration files in the following scenario: After a complete client is downloaded and installed and the system administrator modifies server configurations on Manager, developers need to update the configuration files during application development.

- **x86_64**: indicates the client software package that can be deployed on the x86 servers.
- **aarch64**: indicates the client software package that can be deployed on the Kunpeng servers.

NOTE

The cluster supports two types of clients: **x86_64** and **aarch64**. The client type must match the architecture of the node for installing the client. Otherwise, client installation will fail.

Step 3 Select the path for saving the downloaded client file.

You can directly download the client file to the node where the client is to be installed, or download the file to the active OMS node or local computer and copy it to the node where the client is to be installed.

- **Server**: Download the file to the active OMS node of the cluster.

  The generated file is stored in the **/tmp/FusionInsight-Client** directory on the active OMS node by default. You can also store the client file in other directories, and user **omm** has the read, write, and execute permissions on the directory. If the client file already exists in the path, the existing client file will be replaced.

  NOTE

  When a cluster has many services installed, the cluster client file becomes quite large. Additionally, decompressing this file during installation can consume significant disk space. It's recommended to download the client files to a different directory that has ample space, or to promptly remove unnecessary files from the client download directory after installation. Doing so helps avoid exhausting the **/tmp directory**'s disk space, which could interrupt the normal operation of the cluster nodes.

  After the file is generated, copy the obtained package to another directory, for example, **/opt/Bigdata/hadoopclient**, as user **omm** or client installation user.
- **Browser**: Download the file to the local computer.
- **Remote node:** Download the file to a node other than the active OMS node. If you select this option, you need to set the following parameters:

Table 10-53 Parameters

Parameter	Description	Example Value
Save to Path	Path for storing client files. If there is already a client file in the path, it will be overwritten. For a remote node, write permission for the path is required.	/tmp/FusionInsight-Client-Remote/
Host IP Address	IP address of the remote node. **NOTE** The platform type of the remote node must be the same as that of the downloaded client. Otherwise, the client may fail to be installed.	x.x.x.x
Host Port	Host port of the remote node.	22
Username	Username for logging in to the remote node. For a remote node, write permission for the path is required.	xxx

Parameter	Description	Example Value
Authentication Method	You can choose one of the following methods: – **Password**: Use the password for login. – **SSH private keys**: Use SSH private keys for login. – **None**: To use this method, passwordless login needs to be enabled for the node.	Password
Password	This parameter is mandatory when **Authentication Method** is set to **Password**. This parameter indicates the password used for login.	xxx
SSH Private Keys	This parameter is mandatory when **Authentication Method** is set to **SSH private keys**. Click **Select File** and select a local file to upload.	-
Auto Deployment	Whether to enable auto deployment. This parameter is mandatory when **Select Client Type** is set to **Complete Client**. – If you set this parameter to **yes**, the client is automatically installed and deployed on the current node. – If you set this parameter to **no**, the client will not be automatically installed and deployed. You need to manually install the client after it is downloaded.	Yes

Parameter	Description	Example Value
Deployment Path	This parameter is mandatory when **Auto Deployment** is set to **Yes**. If only the configuration file is downloaded, this parameter will not be displayed. The deployment path must be empty if it already exists on the remote node. Otherwise, it will be created automatically. The path also requires operate and write permissions.	/opt/testclient

Copy the obtained software package to the file directory (for example, **/tmp/FusionInsight-Client**) of the server where the client is to be installed as the user (for example, **user_client**) who is preparing to install the client.

The name of the client software package is in the following format: **FusionInsight_Cluster_*<Cluster ID>*_Services_Client.tar**.

The following steps and sections use **FusionInsight_Cluster_1_Services_Client.tar** as an example.

NOTE

The host where the client is to be installed can be a node inside or outside the cluster. If the node is a server outside the cluster, it must be able to communicate with the cluster, and the NTP service must be enabled to ensure that the time is the same as that on the server.

For example, you can configure the same NTP clock source for external servers as that of the cluster. After the configuration, you can run the **ntpq -np** command to check whether the time is synchronized.

- If there is an asterisk (*) before the IP address of the NTP clock source in the command output, the synchronization is normal. For example:

```
remote refid st t when poll reach delay offset jitter
==============================================================================
*10.10.10.162 .LOCL. 1 u 1 16 377 0.270 -1.562 0.014
```

- If there is no asterisk (*) before the IP address of the NTP clock source and the value of **refid** is **.INIT.**, or if the command output is abnormal, the synchronization is abnormal. Contact technical support.

```
remote refid st t when poll reach delay offset jitter
==============================================================================
10.10.10.162 .INIT. 1 u 1 16 377 0.270 -1.562 0.014
```

You can also configure the same chrony clock source for external servers as that for the cluster. After the configuration, run the **chronyc sources** command to check whether the time is synchronized.

- In the command output, if there is an asterisk (*) before the IP address of the chrony service on the active OMS node, the synchronization is normal. For example:

```
MS Name/IP address         Stratum Poll Reach LastRx Last sample
===============================================================================
^* 10.10.10.162              10  10   377   626    +16us[  +15us] +/-  308us
```

- In the command output, if there is no asterisk (*) before the IP address of the NTP service on the active OMS node, and the value of **Reach** is **0**, the synchronization is abnormal.

```
MS Name/IP address         Stratum Poll Reach LastRx Last sample
===============================================================================
^? 10.1.1.1                   0  10     0     -     +0ns[   +0ns] +/-    0ns
```

Step 4 Log in to the server where the client software package is located as user **user_client**.

Step 5 Decompress the software package.

Go to the directory where the installation package is stored, such as **/tmp/FusionInsight-Client**. Run the following command to decompress the installation package to a local directory:

tar -xvf FusionInsight_Cluster_1_Services_Client.tar

Step 6 Verify the software package.

Run the following command to verify the decompressed file and check whether the command output is consistent with the information in the **sha256** file:

sha256sum -c FusionInsight_Cluster_1_Services_ClientConfig.tar.sha256

```
FusionInsight_Cluster_1_Services_ClientConfig.tar: OK
```

Step 7 Decompress the obtained installation file.

tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar

Step 8 Configure network connections for the client.

1. Ensure that the host where the client is installed can communicate with the hosts listed in the **hosts** file in the decompression directory (for example, **/tmp/FusionInsight-Client/FusionInsight_Cluster_*<Cluster ID>*_Services_ClientConfig/hosts**).
2. If the host where the client is installed is not a host in the cluster, you need to set the mapping between the host name and the service plane IP address for each cluster node in **/etc/hosts**, as user **root**. Each host name uniquely maps an IP address. You can perform the following steps to import the domain name mapping of the cluster to the **hosts** file:
   a. Switch to user **root** or a user who has the permission to modify the **hosts** file.

      su - root

   b. Go to the directory where the client package is decompressed.

      cd /tmp/FusionInsight-Client/FusionInsight_Cluster_1_Services_ClientConfig

   c. Run the **cat realm.ini >> /etc/hosts** command to import the domain name mapping to the **hosts** file.

NOTE

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- If Spark tasks are executed in yarn-client mode, add the **spark.driver.host** parameter to the file *Client installation directory*/**Spark/spark/conf/spark-defaults.conf** and set the parameter to the client IP address.
- If the yarn-client mode is used, you need to configure the mapping between the IP address and host name of the client in the **hosts** file on the active and standby Yarn nodes (ResourceManager nodes in the cluster) to make sure that the Spark web UI is properly displayed.

Step 9 Go to the directory where the installation package is stored, and run the following command to install the client to a specified directory (an absolute path), for example, **/opt/client**. The client installation directory can contain only uppercase letters, lowercase letters, digits, and underscores (_).

cd /tmp/FusionInsight-Client/FusionInsight_Cluster_1_Services_ClientConfig

Run the **./install.sh /opt/client** command to install the client. The client is successfully installed if information similar to the following is displayed:

```
ALL component client is installed successfully
```

NOTE

- If the **/opt/hadoopclient** directory has been used by existing service clients, you need to use another directory in this step when installing other service clients.
- You must delete the client installation directory when uninstalling a client.
- To ensure that an installed client can only be used by the installation user (for example, **user_client**), add parameter **-o** during the installation. That is, run the **./install.sh /opt/client -o** command to install the client.
- If the server where the client is to be installed is in the cluster, you do not need to specify the NTP server mode. You can run the **./install.sh /opt/client** command to install the client.
- If the server where the client is to be installed is outside the cluster and the NTP server mode is **chrony**, run the **./install.sh /opt/client -o chrony** command to install the client. If the NTP server mode is not specified, the NTP server mode in the cluster is used by default.
- If you do not need to verify clock synchronization during client installation, run the **./install.sh /opt/client -u** command to install the client.
- If you do not need to verify clock synchronization during client installation and the installed client can be used by the installation user only (for example, **user_client**), add the **-ou** parameter during the installation, that is, run the **./install.sh /opt/client -ou** command to install the client.
- If the client node is a server outside the cluster and cannot communicate with the service plane IP address of the active OMS node or cannot access port 20029 of the active OMS node, the client can be successfully installed but cannot be registered with the cluster or displayed on the UI.

Step 10 Log in to the client to check whether the client is successfully installed.

1. Run the **cd /opt/client** command to go to the client installation directory.
2. Run the **source bigdata_env** command to configure environment variables for the client.
3. Run related commands based on the cluster mode.
   - For a cluster in normal mode, directly run commands related to the component client, for example, **hdfs**.
   - For a cluster in security mode, run the following command to set **kinit** authentication and enter the password for logging in to the client. For a cluster in normal mode, user authentication is not required.

     kinit admin

     ```
     Password for xxx@HADOOP.COM: #Enter the login password of user admin (same as the user password for logging in to the cluster).
     ```

     Run the **klist** command to query and confirm authentication details.

     ```
     Ticket cache: FILE:/tmp/krb5cc_0
     Default principal: xxx@HADOOP.COM

     Valid starting       Expires              Service principal
     04/09/2021 18:22:35  04/10/2021 18:22:29  krbtgt/HADOOP.COM@HADOOP.COM
     ```

NOTE

- When kinit authentication is used, the ticket is stored in the **/tmp/krb5cc**_*uid* directory by default.

  uid indicates the ID of the user who logs in to the OS. For example, if the UID of user **root** is 0, the ticket generated for kinit authentication after user **root** logs in to the system is stored in the **/tmp/krb5cc_0** directory.

  If the current user does not have the read/write permission for the **/tmp** directory, the ticket cache path is changed to **Client installation directory/tmp/krb5cc_uid**. For example, if the client installation directory is **/opt/hadoopclient**, the kinit authentication ticket is stored in **/opt/hadoopclient/tmp/krb5cc_uid**.

- If the same user is used to log in to the OS for kinit authentication, there is a risk that tickets are overwritten. You can set the **-c** *cache_name* parameter to specify the ticket cache path or set the **KRB5CCNAME** environment variable to avoid this problem.

Step 11 After the cluster is reinstalled, the previously installed client is no longer available. Perform the following operations to deploy the client again:

1. Log in to the node where the client is deployed as user **root**.
2. Run the following command to view the directory where the client is located: (In the following example, **/opt/hadoopclient** is the directory where the client is located.)

   ll /opt

   ```
   drwxr-x---. 6 root root      4096 Dec 11 19:00 hadoopclient
   drwxr-xr-x. 3 root root      4096 Dec  9 02:04 godi
   drwx------. 2 root root     16384 Nov  6 01:03 lost+found
   drwxr-xr-x. 2 root root      4096 Nov  7 09:49 rh
   ```

3. Run the following command to delete the files in the folder (for example, **/opt/client**) where all client programs are located:

   mv /opt/client */tmp/clientbackup*

4. Reinstall the client.

----End

10.9.1.2 Using a Client

Scenario

After the client is installed, you can use the shell command on the client in O&M or service scenarios, or use the sample project on the client during application development.

This section describes how to use the client in O&M scenario or service scenarios.

Prerequisites

- You have installed the client.

  For example, the installation directory is **/opt/client**.

- Service users of each component have been created by the system administrator based on service requirements.

A machine-machine user needs to download the **keytab** file and a human-machine user needs to change the password upon the first login.

Procedure

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to switch to the client installation directory:

cd /opt/client

Step 3 Run the following command to set environment variables:

source bigdata_env

Step 4 If the cluster is in security mode, authenticate the user. For a normal cluster, user authentication is not required.

kinit *Component service user*

Step 5 Run the **shell** command as required.

----End

10.9.1.3 Updating the Configuration of an Installed Client

Scenario

The cluster provides a client for you to connect to a server, view task results, or manage data. If you modify service configuration parameters on FusionInsight Manager and restart the service, you need to download and install the installed client again or use the configuration file to update the client.

Prerequisites

You have installed a client.

Procedure

Method 1:

Step 1 Log in to FusionInsight Manager.

Step 2 In the upper right corner of the home page, click **Download Client** and set **Type** to **Configuration Files Only**.

The generated compressed file contains the configuration files of all services.

NOTE

The cluster supports two types of clients: **x86_64** and **aarch64**. The client type must match the architecture of the node for installing the client. Otherwise, client installation will fail.

Step 3 Select the path for saving the downloaded client configuration file.

- **Server**: Download the file to the active OMS node of the cluster.

  The generated file is stored in the **/tmp/FusionInsight-Client** directory on the active OMS node by default. You can also store the client file in other

directories, and user **omm** has the read, write, and execute permissions on the directory. If the client file already exists in the path, the existing client file will be replaced.

NOTE

When a cluster has many services installed, the cluster client file becomes quite large. Additionally, decompressing this file during installation can consume significant disk space. It's recommended to download the client files to a different directory that has ample space, or to promptly remove unnecessary files from the client download directory after installation. Doing so helps avoid exhausting the **/tmp directory**'s disk space, which could interrupt the normal operation of the cluster nodes.

After the file is generated, copy the obtained package to another directory, for example, **/opt/Bigdata/hadoopclient**, as user **omm** or client installation user.

- **Browser**: Download the file to the local computer.
- **Remote node:** Download the file to a node other than the active OMS node. If you select this option, you need to set the following parameters:

Table 10-54 Parameters

Parameter	Description	Example Value
Save to Path	Path for storing client files. If there is already a client file in the path, it will be overwritten. For a remote node, write permission for the path is required.	/tmp/FusionInsight-Client-Remote/
Host IP Address	IP address of the remote node. **NOTE** The platform type of the remote node must be the same as that of the downloaded client. Otherwise, the client may fail to be installed.	x.x.x.x
Host Port	Host port of the remote node.	22
Username	Username for logging in to the remote node. For a remote node, write permission for the path is required.	xxx
Authentication Method	You can choose one of the following methods: – **Password**: Use the password for login. – **SSH private keys**: Use SSH private keys for login. – **None**: To use this method, passwordless login needs to be enabled for the node.	Password

Parameter	Description	Example Value
Password	This parameter is mandatory when **Authentication Method** is set to **Password**. This parameter indicates the password used for login.	xxx
SSH Private Keys	This parameter is mandatory when **Authentication Method** is set to **SSH private keys**. Click **Select File** and select a local file to upload.	-
Auto Deployment	Whether to enable auto deployment. This parameter is mandatory when **Select Client Type** is set to **Complete Client**. – If you set this parameter to **yes**, the client is automatically installed and deployed on the current node. – If you set this parameter to **no**, the client will not be automatically installed and deployed. You need to manually install the client after it is downloaded.	Yes
Deployment Path	This parameter is mandatory when **Auto Deployment** is set to **Yes**. If only the configuration file is downloaded, this parameter will not be displayed. The deployment path must be empty if it already exists on the remote node. Otherwise, it will be created automatically. The path also requires operate and write permissions.	/opt/testclient

Step 4 Use WinSCP to save the compressed file to the installation directory of the client as the client installation user, such as **/opt/hadoopclient**.

Step 5 Decompress the software package.

Run the following commands to go to the directory where the client is installed, and decompress the file to a local directory. For example, the downloaded client file is **FusionInsight_Cluster_1_Services_Client.tar**.

cd /opt/hadoopclient

tar -xvf FusionInsight_Cluster_1_Services_Client.tar

Step 6 Verify the software package.

Run the following command to verify the decompressed file and check whether the command output is consistent with the information in the **sha256** file:

sha256sum -c FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles.tar.sha256

```
FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles.tar: OK
```

Step 7 Decompress the package to obtain the configuration file.

tar -xvf FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles.tar

Step 8 Run the following command in the client installation directory to update the client using the configuration file:

sh refreshConfig.sh *Client installation directory Directory where the configuration file is located*

For example, run the following command:

sh refreshConfig.sh /opt/hadoopclient /opt/hadoopclient/FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles

If the following information is displayed, the configurations have been updated successfully:

```
Succeed to refresh components client config.
```

----End

Method 2:

Step 1 Log in to the node where the client is installed as user **root**.

Step 2 Go to the client installation directory, for example, **/opt/client**, and run the following commands to update the configuration file:

cd /opt/client

sh autoRefreshConfig.sh

Step 3 Enter the username and password of the FusionInsight Manager administrator and the floating IP address of FusionInsight Manager. You can run the **ifconfig** command on the active OMS node to view the floating IP address.

Step 4 Enter the names of the components whose configurations need to be updated. Use commas (,) to separate the component names. Press **Enter** to update the configurations of all components if necessary.

If the following information is displayed, the configurations have been updated successfully:

```
Succeed to refresh components client config.
```

----End

10.9.2 Cluster Mutual Trust Management

10.9.2.1 Overview of Mutual Trust Between Clusters

Function Description

By default, users of a big data cluster in security mode can only access resources in the cluster but cannot perform identity authentication or access resources in other clusters in security mode.

Feature Description

- **Domain**

  The secure usage scope of users in each system is called a domain. Each FusionInsight Manager must have a unique domain name. Cross-Manager access allows users to use resources across domains.

- **User Encryption**

  Mutual trust can be configured across FusionInsight Managers. The current Kerberos server supports only the aes256-cts-hmac-sha1-96:normal and aes128-cts-hmac-sha1-96:normal encryption types for encrypting cross-domain users, and the encryption types cannot be changed.

- **User Authentication**

  After cross-Manager mutual trust is configured, if a user with the same name exists in two systems and the user in the peer system has the permission to access a resource in that system, this user can also access the remote resource.

- **Direct Mutual Trust**

  The system saves the mutual trust ticket of the peer system in two clusters with mutual trust configured and uses the mutual trust ticket to access the peer system.

10.9.2.2 Changing Manager's Domain Name

Scenario

The secure usage scope of users in each system is called a domain. Each system must have a unique domain name. The domain name of FusionInsight Manager is generated during installation. The system administrator can change the domain name on FusionInsight Manager.

NOTICE

- Changing the system domain name is a high-risk operation. Before performing operations in this section, ensure that the OMS data has been backed up by referring to **Backing Up Manager Data**.

Impact on the System

- During the configuration, all of the clusters need to be restarted and are unavailable during restart.
- After the domain name is changed, the passwords of the Kerberos administrator and OMS Kerberos administrator will be initialized. You need to use the default passwords and then change the passwords. If a component user whose password is generated randomly by the system is used for identity authentication, see **Exporting an Authentication Credential File** to download the keytab file again.
- After the domain name is changed, passwords of the **admin** user, component user, and human-machine user added by the system administrator before the domain name change will be reset to the same one. Change these passwords. The reset password consists of two parts: one part is generated by the system and the other is set by the user. The system generating part is **Admin@123**, which is the default password. For details about the user-defined part, see descriptions of **Password Suffix** in **Table 10-56**. For example, if the system generates **Admin@123** and the user sets **Test#$%@123**, the new password after reset is **Admin@123Test#$%@123**.
- The new password must meet the password policies. To obtain the new human-machine user password, log in to the active OMS as user **omm** and run the following script:

  sh ${BIGDATA_HOME}/om-server/om/sbin/get_reset_pwd.sh *Password suffix user_name*

  – *Password suffix* is a parameter set by the user. If it is not specified, the default value **Admin@123** is used.

  – *user_name* is optional. The default value is **admin**.

  Example:

  sh ${BIGDATA_HOME}/om-server/om/sbin/get_reset_pwd.sh Test#$%@123

  ```
  To get the reset password after changing cluster domain name.
    pwd_min_len      : 8
    pwd_char_types   : 4
  The password reset after changing cluster domain name is: "Admin@123Test#$%@123"
  ```

  In this example, **pwd_min_len** and **pwd_char_types** indicate the minimum password length and number of password character types respectively defined in the password policies. **Admin@123Test#$%@123** indicates the human-machine user password after the system domain name is changed. Commands carrying authentication passwords pose security risks. Disable historical command recording before running such commands to prevent information leakage.
- After the system domain name is changed, the reset password consists of two parts: one part is generated by the system and the other is set by the user. The reset password must meet the password policies. If the password is not long enough, one or multiple at signs (@) are added between **Admin@123** and the user-defined part. If there are five character types, a space is added after **Admin@123**.

  When the user-defined part is **Test@123** and the default user password policy is used, the new password is **Admin@123Test@123**. The password contains 17 characters of four types. To meet the current password policy, the new password is processed according to **Table 10-55**.

Table 10-55 Password processing

Minimum Password Length	Number of Character Types	Processing Against the Password Policy	New Password
8 to 17 characters	4	The user password policy is met.	Admin@123Test@123
18 characters	4	Add an at sign (@).	Admin@123@Test@123
19 characters	4	Add two at signs (@).	Admin@123@@Test@123
8 to 18 characters	5	Add a space.	Admin@123 Test@123
19 characters	5	Add a space and an at sign (@).	Admin@123 @Test@123
20 characters	5	Add a space and two at signs (@).	Admin@123 @@Test@123

- After the system domain name is changed, download the **keytab** file for the machine-machine user added by the system administrator before the domain name is changed.
- After the system domain name is changed, download and install the client again.

Prerequisites

- The system administrator has clarified service requirements and planned domain names for the systems.

  A domain name can contain only uppercase letters, numbers, periods (.), and underscores (_), and must start with a letter or number.
- The running status of all components in the Manager clusters is **Normal**.
- The **acl.compare.shortName** parameter of the ZooKeeper service of all clusters in Manager is set to default value **true**. Otherwise, change the value to **true** and restart the ZooKeeper service.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **Domain and Mutual Trust**.

Step 3 Modify required parameters.

Table 10-56 Related parameters

Parameter	Description
Local Domain	Planned domain name of the system.

Parameter	Description
Password Suffix	Part of the password set by the user after the password of the human-machine user is reset. This parameter is mandatory. The default value is **Admin@123**. **NOTE** This parameter takes effect only after **Local Domain** is modified. The following conditions must be met: • The password ranges from 8 to 16 characters. • The password must contain at least three types of the following: uppercase letters, lowercase letters, numbers, and special characters (`~!@#$%^&*()-_=+|[{}];:',<.>/? and spaces).

Step 4 Click **OK**. Proceed with the subsequent steps only after the modification is complete.

Step 5 Log in to the active management node as user **omm**.

Step 6 Run the following command to update the domain configuration:

sh ${BIGDATA_HOME}/om-server/om/sbin/restart-RealmConfig.sh

The command is successfully executed if the following information is displayed:

```
Modify realm successfully. Use the new password to log into FusionInsight again.
```

NOTE

After the restart, some hosts and services cannot be accessed and an alarm is generated. This problem can be automatically resolved in about 1 minute after **restart-RealmConfig.sh** is run.

Step 7 Use the new admin username and password (for example, **Admin@123Admin@123**) to log in to FusionInsight Manager. In the upper right corner of **Homepage**, click **More** and select **Restart** to restart the cluster.

In the displayed dialog box, enter the password of the current login user and click **OK**.

In the displayed dialog box, click **OK**. Wait for a while until a message indicating that the operation is successful is displayed. Click **Finish**.

Step 8 Log out of FusionInsight Manager and then log in again. If the login is successful, the configuration is successful.

Step 9 Log in to the active management node as user **omm** and run the following command to update the configurations of the job submission client:

sh /opt/executor/bin/refresh-client-config.sh

----End

10.9.2.3 Configuring Cross-Manager Mutual Trust Between Clusters

Scenario

When two security-mode clusters managed by different FusionInsight Managers need to access each other's resources, the system administrator can configure cross-Manager mutual trust for them.

The secure usage scope of users in each system is called a domain. Each FusionInsight Manager must have a unique domain name. Cross-Manager access allows users to use resources across domains.

NOTE

A maximum of 500 mutually trusted clusters can be configured in the system.

Impact on the System

- After cross-Manager cluster mutual trust is configured, users of an external system can be used in the local system. The system administrator needs to periodically check the user permissions in Manager based on enterprise service and security requirements.
- When cross-Manager cluster mutual trust is configured, all clusters need to be stopped, causing service interruptions.
- After cross-Manager cluster mutual trust is configured, internal Kerberos users **krbtgt/***Local cluster domain name*@*External cluster domain name* and **krbtgt/***External cluster domain name*@*Local cluster domain name* are added to the two mutually trusted clusters. The internal users cannot be deleted. The system administrator needs to change the passwords periodically based on enterprise service and security requirements. The passwords of these four users in the two systems must be the same. For details, see **Changing the Password for a Component Running User**. When the passwords are changed, the connectivity between cross-cluster service applications may be affected.
- After cross-Manager cluster mutual trust is configured, the clients of each cluster need to be downloaded and installed again.
- After cross-Manager cluster mutual trust is configured, you need to check whether the system works properly and how to access resources of the peer system as a user of the local system. For details, see **Assigning User Permissions After Cross-Cluster Mutual Trust Is Configured**.

Prerequisites

- The system administrator has clarified service requirements and planned domain names for the systems. A domain name can contain only uppercase letters, numbers, periods (.), and underscores (_), and must start with a letter or number.
- The domain names of the two Managers are different. When an ECS or BMS cluster is created on MRS, a unique system domain name is randomly generated. Generally, you do not need to change the system domain name.
- The two clusters do not have the same host name or the same IP address.
- The system time of the two clusters is consistent, and the NTP services in the two systems use the same clock source.

- The running status of all components in the two clusters is **Normal**.
- The **acl.compare.shortName** parameter of the ZooKeeper service of all clusters in Manager is set to default value **true**. Otherwise, change the value to **true** and restart the ZooKeeper service.

Procedure

Step 1 Log in to one FusionInsight Manager.

Step 2 In the upper right corner of **Homepage**, click **Stop**. Enter the password of the cluster administrator. In the **Stop Cluster** dialog box that is displayed, click **OK**. Wait until the cluster is successfully stopped.

Step 3 Choose **System** > **Permission** > **Domain and Mutual Trust**.

Step 4 Modify **Peer Mutual Trust Domain**.

Table 10-57 Related parameters

Parameter	Description
realm_name	Enter the domain name of the peer system.
ip_port	Enter the KDC address of the peer system. Value format: *IP address of the node accommodating the Kerberos service in the peer system:Port number* ● In dual-plane networking, enter the service plane IP address. ● If an IPv6 address is used, the IP address must be enclosed in square brackets ([]). ● Use commas (,) to separate the KDC addresses if the active and standby Kerberos services are deployed or multiple clusters in the peer system need to establish mutual trust with the local system. ● You can obtain the port number from the **kdc_ports** parameter of the KrbServer service. The default value is **21732**. To obtain the IP address of the node where the service is deployed, click the **Instance** tab on the KrbServer page and view **Service IP Address** of the KerberosServer role. For example, if the Kerberos service is deployed on nodes at **10.0.0.1** and **10.0.0.2** that have established mutual trust with the local system, the parameter value is **10.0.0.1:21732,10.0.0.2:21732**.

NOTE

If you need to configure mutual trust for multiple Managers, click + to add a new item and set parameters. To delete unnecessary configurations, click −.

Step 5 Click **OK**.

Step 6 Log in to the active management node as user **omm**, and run the following command to update the domain configuration:

sh ${BIGDATA_HOME}/om-server/om/sbin/restart-RealmConfig.sh

The command is successfully executed if the following information is displayed:

```
Modify realm successfully. Use the new password to log into FusionInsight again.
```

After the restart, some hosts and services cannot be accessed and an alarm is generated. This problem can be automatically resolved in about 1 minute after **restart-RealmConfig.sh** is run.

Step 7 Log in to FusionInsight Manager and start the cluster.

Click **Start** in the upper right corner of **Homepage**. In the **Start Cluster** dialog box displayed, click **OK**. Wait until the cluster is successfully started.

Step 8 Log in to the other FusionInsight Manager and repeat the preceding operations.

----End

10.9.2.4 Assigning User Permissions After Cross-Cluster Mutual Trust Is Configured

Scenario

After cross-Manager cluster mutual trust is configured, assign user access permissions on FusionInsight Managers so that these users can perform service operations in the mutually trusted Managers.

Prerequisites

The mutual trust between the two Managers has been configured.

Procedure

Step 1 Log in to the local FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **User** to check whether the target user exists.

- If yes, go to **Step 3**.
- If no, go to **Step 4**.

Step 3 Click ⌄ on the left of the target user, and check whether the permissions assigned to the user group of the user and the roles meet service requirements. If not, create a role and bind the role to the user by referring to **Configuring Permissions**, or modify the user group or role permissions of the user.

Step 4 Create a user required by the service operations and associate the required user group or role. For details, see **Creating a User**.

Step 5 Log in to the other FusionInsight Manager and repeat **Step 2** to **Step 4** to create a user with the same name and set permissions.

----End

10.9.3 Configuring Scheduled Backup of Alarm and Audit Information

Scenario

You can modify the configuration file to periodically back up FusionInsight Manager alarm information, FusionInsight Manager audit information, and audit information of all services to the specified storage location.

The backup can be performed using FTP or SFTP. FTP does not encrypt data, which may cause security risks. Therefore, SFTP is recommended.

Procedure

Step 1 Log in to the active management node as user **omm**.

NOTE

Perform this operation only on the active management node. Scheduled backup is not supported on the standby management node.

Step 2 Run the following command to switch the directory:

cd ${BIGDATA_HOME}/om-server/om/sbin

Step 3 Run the following command to configure scheduled backup of FusionInsight Manager's alarm and audit information or service audit information:

./setNorthBound.sh -t *Information type* **-i** *Remote server IP address* **-p** *SFTP or FTP port used by the server*-**u** *Username* **-d** *Save path* **-c** *Interval (minutes)* **-m** *Number of records in each file* **-s** *Whether to enable backup* **-e** *Protocol*

Example:

./setNorthBound.sh -t alarm -i 10.0.0.10 -p 22 -u sftpuser -d /tmp/ -c 10 -m 100 -s true -e sftp

This script modifies the alarm backup configuration file **alarm_collect_upload.properties**. The file save path is **${BIGDATA_HOME}/om-server/tomcat/webapps/web/WEB-INF/classes/config**.

./setNorthBound.sh -t audit -i 10.0.0.10 -p 22 -u sftpuser -d /tmp/ -c 10 -m 100 -s true -e sftp

This script modifies the audit backup configuration file **audit_collect_upload.properties**. The file save path is **${BIGDATA_HOME}/om-server/tomcat/webapps/web/WEB-INF/classes/config**.

./setNorthBound.sh -t service_audit -i 10.0.0.10 -p 22 -u sftpuser -d /tmp/ -c 10 -m 100 -s true -e sftp

This script modifies the service audit backup configuration file **service_audit_collect_upload.properties**. The file save path is **${BIGDATA_HOME}/om-server/tomcat/webapps/web/WEB-INF/classes/config**.

Step 4 Enter the password as prompted. The password is encrypted and saved in the configuration file.

```
Please input sftp/ftp server password:
```

Step 5 Check the configuration result. If the following information is displayed, the configuration is successful. The configuration file will be automatically synchronized to the standby management node.

```
execute command syncfile successfully.
Config Succeed.
```

----End

10.9.4 Modifying the FusionInsight Manager Routing Table

Scenario

When FusionInsight Manager is installed, two pieces of routing information are automatically created on the active management node. You can run the **ip rule list** command to view the routing information, as shown in the following example:

```
0:from all lookup local
32764:from all to 10.10.100.100 lookup ntp_rt   #NTP routing information created by FusionInsight Manager (this information is unavailable if no external NTP clock source is configured).
32765:from 192.168.0.117 lookup om_rt   #OM routing information created by the FusionInsight Manager.
32766:from all lookup main
32767:from all lookup default
```

NOTE

If no external NTP server has been configured, only the OM routing information will be created.

If the routing information created by FusionInsight Manager conflicts with the routing information configured in the enterprise network planning, the cluster administrator can use **autoroute.sh** to disable or enable the routing information created by FusionInsight Manager.

Impact on the System

After the routing information created by FusionInsight Manager is disabled and before the new routing information is set, FusionInsight Manager cannot be accessed but the clusters are running properly.

Prerequisites

FusionInsight Manager has been installed.

You have obtained routing information about the WS floating IP address.

Disable the Routing Information Created by the System

Step 1 Log in to the active management node as user **omm**. Run the following commands to disable the routing information created by the system:

cd ${BIGDATA_HOME}/om-server/om/sbin

./autoroute.sh disable

```
Deactivating Route.
Route operation (disable) successful.
```

Step 2 Run the following command to view the execution result:

ip rule list

```
0:from all lookup local
32766:from all lookup main
32767:from all lookup default
```

Step 3 Run the following command and enter the password of user **root** to switch to user **root**:

su - root

Step 4 Run the following commands to manually create the routing information about the WS floating IP address:

ip route add *Network segment of the WS floating IP address/Subnet mask of the WS floating IP address* **scope link src** *WS floating IP address* **dev** *NIC of the WS floating IP address* **table om_rt**

ip route add default via *Gateway of the WS floating IP address* **dev** *NIC of the WS floating IP address* **table om_rt**

ip rule add from *WS floating IP address* **table om_rt**

Example:

ip route add 192.168.0.0/255.255.255.0 scope link src 192.168.0.117 dev eth0:ws table om_rt

ip route add default via 192.168.0.254 dev eth0:ws table om_rt

ip rule add from 192.168.0.117 table om_rt

NOTE

If IPv6 addresses are used, run the **ip -6 route add** command.

Step 5 Run the following commands to manually create the NTP service routing information. Skip this step when no external NTP clock source is configured.

ip route add default via *IP gateway of the NTP service* **dev** *NIC of the local IP address* **table ntp_rt**

ip rule add to *ntpIP* **table ntp_rt**

NIC of the local IP address indicates the NIC that can communicate with the network segment where the NTP server is located.

Example:

ip route add default via 10.10.100.254 dev eth0 table ntp_rt

ip rule add to 10.10.100.100 table ntp_rt

Step 6 View the execution result.

In the following example, if the command output contains **om_rt** and **ntp_rt**, the operation is successful.

ip rule list

```
0:from all lookup local
32764:from all to 10.10.100.100 lookup ntp_rt  #This information is not displayed if no external NTP clock source is configured.
```

```
32765:from 192.168.0.117 lookup om_rt
32766:from all lookup main
32767:from all lookup default
```

----End

Enable the Routing Information Created by the System

Step 1 Log in to the active management node as user **omm**.

Step 2 Run the following commands to enable the routing information created by the system:

cd ${BIGDATA_HOME}/om-server/om/sbin

./autoroute.sh enable

```
Activating Route.
Route operation (enable) successful.
```

Step 3 View the execution result.

In the following example, if the command output contains **om_rt** and **ntp_rt**, the operation is successful.

ip rule list

```
0:from all lookup local
32764:from all to 10.10.100.100 lookup ntp_rt  #This information is not displayed if no external NTP clock source is configured.
32765:from 192.168.0.117 lookup om_rt
32766:from all lookup main
32767:from all lookup default
```

----End

10.9.5 Switching to the Maintenance Mode

Scenario

FusionInsight Manager allows you to set clusters, services, hosts, or OMSs to the maintenance mode. Objects in maintenance mode do not report alarms. This prevents the system from generating a large number of unnecessary alarms during maintenance changes, such as upgrade, because these alarms may influence O&M personnel's judgment on the cluster status.

- Cluster maintenance mode

  If a cluster is not brought online or has been brought offline due to O&M operations (for example, non-rolling upgrade), you can set the entire cluster to the maintenance mode.

- Service maintenance mode

  When performing maintenance operations on a specific service (for example, performing service-affecting commissioning operations like batch restart of service instances, directly powering on or off nodes of the service, or repairing the service), you can set only this service to the maintenance mode.

- Host maintenance mode

When performing maintenance operations on a host (such as powering on or off, isolating, or reinstalling the host, upgrading its OS, or replacing the host), you can set only this host to the maintenance mode.

- OMS maintenance mode

  When restarting, replacing, or repairing an OMS node, you can set the OMS node to the maintenance mode.

Impact on the System

After the maintenance mode is set, alarms caused by non-maintenance operations are suppressed and cannot be reported. Alarms can be reported only when faults persist after the system exits the maintenance mode. Therefore, exercise caution when setting the maintenance mode.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Set the maintenance mode.

Determine the object to set the maintenance mode based on the service scenario. For details, see **Table 10-58**.

Table 10-58 Setting to the maintenance mode

Scenario	Operation
Configure a cluster to enter the maintenance mode.	1. In the upper right corner of **Homepage**, click **More** and select **Enter Maintenance Mode**. 2. In the displayed dialog box, click **OK**. After the cluster enters the maintenance state, the status of the cluster becomes . After maintenance is complete, click **Exit Maintenance Mode**. The cluster then exits the maintenance mode.
Configure a service to enter the maintenance mode.	1. On FusionInsight Manager, choose **Cluster** > **Services** > *Service name*. 2. On the service details page, click **More** and select **Enter Maintenance Mode**. 3. In the displayed dialog box, click **OK**. After a service enters the maintenance mode, the status of the service becomes in the service list. After maintenance is complete, click **Exit Maintenance Mode**. The service then exits the maintenance mode. **NOTE** When configuring a service to enter the maintenance mode, you are advised to set the upper-layer services that depend on this service to the maintenance mode as well.

Scenario	Operation
Configure a host to the maintenance mode.	1. On FusionInsight Manager, choose **Hosts**. 2. On the **Hosts** page, select the target host, click **More**, and select **Enter Maintenance Mode**. 3. In the displayed dialog box, click **OK**. After the host enters the maintenance mode, the status of the host becomes in the host list. After maintenance is complete, click **Exit Maintenance Mode**. The host then exits the maintenance mode.
Configure the OMS to enter the maintenance mode.	1. On FusionInsight Manager, choose **System** > **OMS** > **Enter Maintenance Mode**. 2. In the displayed dialog box, click **OK**. After the OMS enters the maintenance state, the OMS status becomes . After maintenance is complete, click **Exit Maintenance Mode**. The OMS then exits the maintenance mode.

Step 3 Check the cluster maintenance view.

In the upper right corner of **Homepage**, click **More** and select **Maintenance Mode View**. In the dialog box displayed, view the services and hosts in maintenance mode in the current cluster.

After maintenance is complete, you can select services and hosts in batches in the maintenance mode view and click **Exit Maintenance Mode** to make them exit the maintenance mode.

----End

10.9.6 Routine Maintenance

To ensure long-term and stable running of the system, administrators or maintenance engineers need to periodically check items listed in **Table 10-59** and rectify the detected faults based on the check results. It is recommended that administrators or engineers record the result in each task scenario and sign off based on the enterprise management regulations.

Table 10-59 Routine maintenance check items

Routine Maintenance Frequency	Task Scenario	Check Item
Daily	Check the cluster service status.	• Check whether the running status and configuration status of each service are normal and whether the status icons are green. • Check whether the running status and configuration status of the role instances in each service are normal and whether the status icons are green. • Check whether the active/standby status of role instances in each service can be properly displayed. • Check whether the dashboard of the services and role instances can be displayed properly.
	Check the cluster host status.	• Check whether the running status of each host is normal and whether the status icon is green. • Check the current disk usage, memory usage, and CPU usage of each host. Check whether the current memory usage and CPU usage are increasing.
	Check the cluster alarm information.	Check whether alarms were generated for unhandled exceptions on the previous day, including alarms that were automatically cleared.
	Check the cluster audit information.	Check whether critical and major operations are performed on the previous day and whether the operations are valid.
	Check the cluster backup status.	Check whether OMS, DBService, NameNodeOMS, DBServiceOMS, and LDAP have been automatically backed up on the previous day.
	View the health check result.	Perform a health check on FusionInsight Manager and download the health check report to check whether the current cluster is abnormal. You are advised to enable the automatic health check, export the latest cluster health check result, and repair unhealthy items based on the result.

Routine Maintenance Frequency	Task Scenario	Check Item
	Check the network communication.	Check the cluster network status and check whether the network communication between nodes is delayed.
	Check the storage status.	Check whether the total data storage volume of the cluster increases abruptly. ● Check whether the disk usage is close to the threshold. If yes, locate the causes. For example, check whether the junk data or cold data left by services needs to be cleared. ● Check whether disk partitions need to be expanded based on the service growth trend.
	Check logs.	● Check whether there are failed or unresponsive MapReduce and Spark tasks. Check the **/tmp/logs/${username}/logs/${application id}** log file in HDFS and rectify faults. ● Check Yarn task logs, view the logs of failed and unresponsive tasks, and delete duplicate data. ● Back up logs to the storage server.
Weekly	Manage users.	Check whether the user password is about to expire and notify the user of changing the password. To change the password of a machine-machine user, you need to download the keytab file again.
	Analyze alarms.	Export and analyze alarms generated in a specified period.
	Scan disks.	Check the disk health status. You are advised to use a dedicated disk check tool.
	Collect statistics on storage.	Check in batches whether the disk data of cluster nodes is evenly stored, filter out the disks whose data increases significantly or is insufficient, and check whether the disks are normal.
	Record changes.	Arrange and record the operations on cluster configuration parameters and files to provide reference for fault analysis and handling.

Routine Maintenance Frequency	Task Scenario	Check Item
Monthly	Analyze logs.	• Collect and analyze hardware logs of cluster node servers, such as BMC system logs. • Collect and analyze the OS logs of the cluster node servers. • Collect and analyze cluster logs.
	Diagnose the network.	Analyze the network health status of the cluster.
	Manage hardware.	Check the equipment room environment and clean the devices.

10.10 Log Management

10.10.1 About Logs

Log Description

MRS cluster logs are stored in the **/var/log/Bigdata** directory. The following table lists the log types.

Table 10-60 Log types

Log Type	Description
Installation logs	Installation logs record information about FusionInsight Manager, cluster, and service installation to help users locate installation errors.
Run logs	Run logs record the running track information, debugging information, status changes, potential problems, and error information generated during the running of services.
Audit logs	Audit logs record information about users' activities and operation instructions, which can be used to locate fault causes in security events and determine who are responsible for these faults.

The following table lists the MRS log directories.

Table 10-61 Log directories

Directory	Log
/var/log/Bigdata/audit	Component audit log.
/var/log/Bigdata/controller	Log collecting script log. Controller process log. Controller monitoring log.
/var/log/Bigdata/dbservice	DBService log.
/var/log/Bigdata/flume	Flume log.
/var/log/Bigdata/ftp-server	FTP server log.
/var/log/Bigdata/hbase	HBase log.
/var/log/Bigdata/hdfs	HDFS log.
/var/log/Bigdata/hive	Hive log.
/var/log/Bigdata/hetuengine	HetuEngine log.
/var/log/Bigdata/httpd	HTTPd log.
/var/log/Bigdata/hue	Hue log.
/var/log/Bigdata/kerberos	Kerberos log.
/var/log/Bigdata/ldapclient	LDAP client log.
/var/log/Bigdata/ldapserver	LDAP server log
/var/log/Bigdata/loader	Loader log.
/var/log/Bigdata/logman	Logman script log management log
/var/log/Bigdata/mapreduce	MapReduce log.
/var/log/Bigdata/nodeagent	NodeAgent log.
/var/log/Bigdata/okerberos	OMS Kerberos log.
/var/log/Bigdata/oldapserver	OMS LDAP log.
/var/log/Bigdata/metric_agent	Run log file of MetricAgent
/var/log/Bigdata/omm	**oms**: complex event processing log, alarm service log, HA log, authentication and authorization management log, and monitoring service run log of the OMM server. **oma**: installation log and run log of the OMM agent. **core**: dump log generated when the OMM agent and the HA process are suspended.
/var/log/Bigdata/spark	Spark log.

Directory	Log
/var/log/Bigdata/sudo	Log generated when the **sudo** command is executed by user **omm**.
/var/log/Bigdata/timestamp	NodeAgent startup time log.
/var/log/Bigdata/tomcat	Tomcat log.
/var/log/Bigdata/yarn	Yarn log.
/var/log/Bigdata/zookeeper	ZooKeeper log.
/var/log/Bigdata/oozie	Oozie log.
/var/log/Bigdata/solr	Solr log.
/var/log/Bigdata/elasticsearch	Elasticsearch log.
/var/log/Bigdata/kafka	Kafka log.
/var/log/Bigdata/redis	Redis log.
/var/log/Bigdata/metadata	Metadata log.
/var/log/Bigdata/iotdb	IoTDB log.
/var/log/Bigdata/cdl	CDL log.
/var/log/Bigdata/upgrade	OMS upgrade log.
/var/log/Bigdata/update-service	Upgrade service log.
/var/log/Bigdata/motservice	MOTService log.
/var/log/Bigdata/containers	Containers log.
/var/log/Bigdata/rtd	RTDService log.
/var/log/Bigdata/job-gateway	JobGateway log.
/var/log/Bigdata/doris	Doris log.
/var/log/Bigdata/guardian	Guardian log.
/var/log/Bigdata/memartscc	MemArtsCC log.

NOTE

After the multi-instance function is enabled, if the system administrator adds multiple HBase, Hive, and Spark service instances, the log description, log level, and log format of the newly added service instances are the same as those of the original service logs. Service instance logs are stored separately in the **/var/log/Bigdata/***servicenameN* directory. The audit logs of the HBase and Hive service instances are stored in the **/var/log/Bigdata/audit/***servicenameN* directory. For example, the logs of HBase1 are stored in the **/var/log/Bigdata/hbase1** and **/var/log/Bigdata/audit/hbase1** directories.

Installation Logs

Table 10-62 Installation logs

Installation Log	Description
Configuration log	Records information about the configuration process before the installation.
FusionInsight Manager installation log	Records information about the two-node FusionInsight Manager installation.
Cluster installation log	Records information about the cluster installation.

Run Logs

Table 10-63 describes the running information recorded in run logs.

Table 10-63 Running information

Run Log	Description
Installation preparation log	Records information about preparations for the installation, such as the detection, configuration, and feedback operation information.
Process startup log	Records information about the commands executed during the process startup.
Process startup exception log	Records information about exceptions during process startup, such as dependent service errors and insufficient resources.
Process run log	Records information about the process running track information and debugging information, such as function entries and exits as well as cross-module interface messages.

Run Log	Description
Process running exception log	Records errors that cause process running errors, for example, the empty input objects or encoding or decoding failure.
Process running environment log	Records information about the process running environment, such as resource status and environment variables.
Script log	Records information about the script execution process.
Resource reclamation log	Records information about the resource reclaiming process.
Uninstallation clearing logs	Records information about operations performed during service uninstallation, such as directory and execution time deletion.

Audit Logs

Audit information recorded in audit logs includes FusionInsight Manager audit information and component audit information.

Table 10-64 Audit information of FusionInsight Manager

Operation Type	Operation
User management	Creating a user. Modifying a user. Deleting a user. Creating a user group. Modifying a user group. Deleting a group. Adding a role. Changing the user's roles. Deleting a role. Changing a password policy. Changing a password. Resetting a password. Logging in. Logging out. Unlocking the screen. Downloading the authentication credential. Unauthorized operation. Unlocking a user account. Locking a user account. Locking the screen. Exporting a user. Exporting a user group. Exporting a role.

Operation Type	Operation
Cluster management	Starting a cluster. Stopping a cluster. Restarting a cluster. Performing a rolling restart of a cluster. Restarting all expired instances. Saving configurations. Synchronizing cluster configurations. Customizing cluster monitoring metrics. Configuring monitoring dumping. Saving monitoring thresholds. Downloading a client configuration file. Configuring the northbound Syslog interface. Configuring the northbound SNMP interface. Clearing alarms using SNMP. Adding a trap target using SNMP. Deleting a trap target using SNMP. Checking alarms using SNMP. Synchronizing alarms using SNMP. Creating a threshold template. Deleting a threshold template. Applying a threshold template. Saving cluster monitoring configurations. Exporting configurations. Importing cluster configurations. Exporting an installation template. Modifying a threshold template. Canceling the application of a threshold template. Masking an alarm. Sending an alarm. Changing the OMS database password. Resetting the component database password. Restarting OMM and Controller. Starting the health check of a cluster. Importing a certificate file. Configuring SSO information. Deleting historical health check reports. Modifying cluster properties.

Operation Type	Operation
	Running maintenance commands in synchronous mode. Running maintenance commands in asynchronous mode. Customizing report monitoring metrics. Exporting report monitoring data. Runing a command in asynchronous mode using SNMP. Restarting the Web service. Customizing monitoring metrics for static resource pools. Exporting monitoring data of a static resource pool. Customizing dashboard monitoring metrics. Stopping a task. Restoring configurations. Modifying domain and mutual trust configurations. Modifying system parameters. Making a cluster enter the maintenance mode. Making a cluster exit the maintenance mode. Making OMS enter the maintenance mode. Making OMS exit the maintenance mode. Exiting the maintenance mode in batches Modifying OMS configurations. Enabling threshold alarms. Synchronizing all cluster configurations. Support KMS Service

Operation Type	Operation
Service management	Starting a service. Stopping a service. Synchronizing service configurations. Refreshing a service queue. Customizing service monitoring metrics. Restarting a service. Performing a rolling service restart. Exporting service monitoring data. Importing service configuration data. Starting the health check of a service. Configuring a service. Uploading a configuration file. Downloading a configuration file. Synchronizing instance configurations. Commissioning an instance. Decommissioning an instance. Starting an instance. Stopping an instance. Customizing instance monitoring metrics. Restarting an instance. Performing a rolling restart of an instance. Exporting instance monitoring data. Importing instance configuration data. Creating an instance group. Modifying an instance group. Deleting an instance group. Moving an instance to another instance group. Making a service enter the maintenance mode. Making a service exit the maintenance mode. Changing the name of a service. Modifying service association. Downloading monitoring data. Masking alarms. Unmasking alarms. Exporting report data of a service. Adding custom parameters for a report. Modifying custom parameters of a report. Deleting custom parameters of a report.

Operation Type	Operation
	Switching over control nodes. Adding a mount table. Modifying a mount table.
Host management	Setting a node rack. Starting all roles. Stopping all roles. Isolating a host. Canceling isolation of a host. Customizing host monitoring metrics. Exporting host monitoring data. Making a host enter the maintenance mode. Making a host exit the maintenance mode. Exporting basic host information. Exporting host distribution report data. Exporting host trend report data. Exporting host cluster report data. Exporting report data of a service. Customizing host cluster monitoring metrics. Customizing host cluster trend monitoring metrics.
Alarm management	Exporting alarms. Clearing alarms. Exporting events. Clearing alarms in batches.
Log collection	Collecting log files. Downloading log files. Collecting service stack information. Collecting instance stack information. Preparing service stack information. Preparing instance stack information. Clearing service stack information. Clearing instance stack information.
Audit log management	Modifying audit dumping configurations. Exporting audit logs.

Operation Type	Operation
Data backup and restoration	Creating a backup task. Executing a backup task. Executing backup tasks in batches. Stopping a backup task. Deleting a backup task. Modifying a backup task. Locking a backup task. Unlocking a backup task. Creating a restoration task. Executing a restoration task. Stopping a restoration task. Retrying a restoration task. Deleting a restoration task.

Operation Type	Operation
Multi-tenant management	Saving static configurations. Adding a tenant. Downloading tenants. Exporting tenants. Deleting a tenant. Associating a service with a tenant. Deleting a service from a tenant. Configuring resources. Creating a resource. Deleting a resource. Adding a resource pool. Modifying a resource pool. Deleting a resource pool. Restoring tenant data. Modifying global configurations of a tenant. Modifying queue configurations of a capacity scheduler. Modifying queue configurations of a super scheduler. Modifying resource distribution of a capacity scheduler. Clearing resource distribution of a capacity scheduler. Modifying resource distribution of a super scheduler. Clearing resource distribution of a super scheduler. Adding a resource catalog. Modifying a resource catalog. Deleting a resource catalog. Customizing tenant monitoring metrics.

Operation Type	Operation
Health check	Starting the health check of a cluster. Starting the health check of a service. Starting the health check of a host. Starting the health check of OMS. Starting the system health check. Updating the health check configurations. Exporting health check reports. Exporting health check results of a cluster. Exporting health check results of a service. Exporting health check results of a host. Deleting historical health check reports. Exporting historical health check reports. Downloading a health check report.

Table 10-65 Component audit information

Audit Log	Operation Type	Operation
CDL audit log	Service operations	Creating a link. Deleting a link. Creating a job. Starting a Job. Deleting a job.
IoTDB audit log	Maintenance management	Granting permissions. Revoking permissions. Recording authentication and login information.
	Service operations	Deleting a time series, partition, function, or index. Modifying a time series.
ClickHouse audit log	Maintenance management	Granting permissions. Revoking permissions. Recording authentication and login information.
	Service operations	Creating databases or tables. Inserting, deleting, querying, and migrating data.
DBService audit log	Maintenance management	Performing backup restoration operations.

Audit Log	Operation Type	Operation
Elasticsearch audit log	Maintenance management	Authenticating users.
	Service operations	Creating an index.
FTP server audit log	Login operations	Logging in.
	File operations	Creating a file. Deleting a file. Creating a directory. Moving a file. Setting access permissions.
HBase audit log	Data definition language (DDL) statements	Creating a table. Deleting a table. Modifying a table. Adding a column family. Modifying a column family. Deleting a column family. Enabling a table. Disabling a table. Modifying user information. Changing a password. Logging in.
	Data manipulation language (DML) statements	Putting data (to the **hbase:meta**, **_ctmeta_**, and **hbase:acl** tables). Deleting data (from the **hbase:meta**, **_ctmeta_**, and **hbase:acl** tables). Checking and putting data (to the **hbase:meta**, **_ctmeta_**, and **hbase:acl** tables). Checking and deleting data (from the **hbase:meta**, **_ctmeta_**, and **hbase:acl** tables).
	Permission control	Assigning permissions to a user. Canceling permission assigning.
HDFS audit log	Permission management	Managing access permissions on files or folders. Managing the owner information of files or folders.

Audit Log	Operation Type	Operation
	File operations	Creating a folder. Creating a file. Opening a file. Appending file content. Changing a file name. Deleting a file or folder. Setting time property of a file. Setting the number of file copies. Merging files. Checking the file system. Linking to a file.
Hive audit log	Metadata operations	Defining metadata, such as creating databases and tables. Deleting metadata, such as deleting databases and tables. Modifying metadata, such as adding columns and renaming tables. Importing and exporting metadata.
	Data maintenance	Loading data to a table. Inserting data into a table.
	Permission management	Creating or deleting a role. Granting/Reclaiming roles. Granting/Reclaiming permissions.
Hue audit log	Service startup	Starting Hue.
	User operations	Logging in. Logging out.
	Task operations	Creating a task. Modifying a task. Deleting a task. Submitting a task. Saving a task. Updating the status of a task.
KrbServer audit log	Maintenance management	Changing the password of a Kerberos account. Adding a Kerberos account. Deleting a Kerberos account. Authenticating users.

Audit Log	Operation Type	Operation
LdapServer audit log	Maintenance management	Adding an OS user. Adding a user group. Adding a user to a user group. Deleting a user. Deleting a group.
Loader audit log	Security management	Logging in.
	Metadata management	Querying connector information. Querying a framework. Querying step information.
	Data source connection management	Querying a data source connection. Adding a data source connection. Updating a data source connection. Deleting a data source connection. Activating a data source connection. Disabling a data source connection.
	Job management	Querying a job. Creating a job. Updating a job. Deleting a job. Activating a job. Disabling a job. Querying all execution records of a job. Querying the latest execution record of a job. Submitting a job. Stopping a job.
MapReduce audit log	Application running	Starting a container request. Stopping a container request. After a container request is complete, the status of the request becomes successful. After a container request is complete, the status of the request becomes failed. After a container request is complete, the status of the request becomes suspended. Submitting a task. Ending a task.

Audit Log	Operation Type	Operation
Metadata audit log	Task operations	Saving user-defined metadata tag information. Saving configurations. Updating metadata. Uploading FTP. Automatically updating metadata. Automatically uploading FTP.
Oozie audit log	Task management	Submitting a task. Starting a task. Killing a task. Suspending a task. Resuming a task. Running a task again.
Redis audit log	Maintenance management	Creating a Redis cluster. Deleting a Redis cluster. Scaling out a Redis cluster. Scaling in a Redis cluster. Balancing Redis cluster data.
Solr audit log	Maintenance management	Authenticating users. Creating a core. Creating a collection.
	Service operations	Creating an index.
Spark audit log	Metadata operations	Defining metadata, such as creating databases and tables. Deleting metadata, such as deleting databases and tables. Modifying metadata, such as adding columns and renaming tables. Importing and exporting metadata.
	Data maintenance	Loading data to a table. Inserting data into a table.
Yarn audit log	Job submission	Submitting a job to a queue.
ZooKeeper audit log	Permission management	Setting access permissions to Znode.

Audit Log	Operation Type	Operation
	Znode operations	Creating Znodes. Deleting Znodes. Configuring Znode data.
HetuEngine audit log	Job management	Adding an external data source. Deleting an external data source. Modifying an external data source. Creating a compute instance. Starting a compute instance. Stopping a compute instance. Deleting a compute instance. Querying a compute instance. Modifying compute instance configurations.
Containers audit log	Job management	Bringing the decision-making engine online Clearing a BLU Adding a BLU Updating a BLU Adding a BLU instance Deleting a BLU instance Stopping a BLU instance Downloading BLU configuration Deleting a configuration set Downloading a configuration set Updating a configuration set Adding a group Modifying a group Operating a task Rolling back a task
MOTService audit log	User operations	Logging in and out Starting, stopping, restoring, and switching over the database instance Locking and unlocking a user Granting and revoking user permissions Performing CREATE, ALTER, DROP, and COPY operations on DATABASE, SCHEMA, USER, and DATA SOURCE database objects

Audit Log	Operation Type	Operation
RTDService audit log	Job management	Adding, deleting, updating, and listing batch variables, and bringing them online/offline Adding, deleting, updating, and listing data cleansing programs Executing SQL statements and non-query SQL statements, querying table information, and querying column information on DBService Adding and querying schemas on DBService Adding, deleting, deleting all, updating online, updating offline, listing, bringing online/offline, and downloading decision engines Filtering dimensions Adding, deleting, and listing dimensions Adding, updating, deleting, and listing event source mappings, and bringing them online/offline Adding, updating, deleting, and listing event sources, and bringing them online/offline, exporting and executing plug-ins, and exporting and importing files Updating and listing event variables, and bringing them online/offline Adding, deleting, updating, listing, importing, and exporting filtering rules, and bringing them online/offline Adding, updating, listing, and deleting prediction variables, and bringing them online/offline. Listing and synchronizing monitoring items Adding, deleting, updating, listing, importing, and exporting stored procedure variables, and bringing them online/offline Listing parent resources and child resources Adding, deleting, updating, listing, importing, and exporting real-time query variables, and bringing them online/offline Adding, deleting, updating, and listing scoring models, bringing them online/offline, and listing model variables Obtaining system information and performing health check Adding, deleting, updating, listing templates

Audit Log	Operation Type	Operation
		Adding, listing, updating, and deleting tenants, and bringing them online/offline Adding, deleting, updating, and listing managed stored procedures; adding, updating, listing, and deleting download window variables and bringing them online/offline
Doris audit log	Maintenance management	Granting and revoking user permissions Recording authentication and login information Expanding and reducing capacity
	Service operations	Creating databases/tables Inserting, deleting, querying, importing, and exporting data

FusionInsight Manager audit logs are stored in the database. You can view and export the audit logs on the **Audit** page.

The following table lists the directories to store component audit logs. Audit log files of some components are stored in **/var/log/Bigdata/audit**, such as HDFS, HBase, MapReduce, Hive, Hue, Yarn, Redis, and ZooKeeper. The component audit logs are automatically compressed and backed up to **/var/log/Bigdata/audit/bk** at 03: 00 every day. A maximum of latest 90 compressed backup files are retained, and the backup time cannot be changed. For details about how to configure the number of reserved audit log files, see **Configuring the Number of Local Audit Log Backups**.

Audit log files of other components are stored in the component log directory.

Table 10-66 Directories for storing component audit logs

Component	Audit Log Directory
DBService	/var/log/Bigdata/audit/dbservice/dbservice_audit.log
HBase	/var/log/Bigdata/audit/hbase/hm/hbase-audit-hmaster.log /var/log/Bigdata/audit/hbase/hm/hbase-ranger-audit-hmaster.log /var/log/Bigdata/audit/hbase/rs/hbase-audit-regionserver.log /var/log/Bigdata/audit/hbase/rs/hbase-ranger-audit-regionserver.log /var/log/Bigdata/audit/hbase/rt/hbase-audit-restserver.log /var/log/Bigdata/audit/hbase/ts/hbase-audit-thriftserver.log

Component	Audit Log Directory
HDFS	/var/log/Bigdata/audit/hdfs/nn/hdfs-audit-namenode.log /var/log/Bigdata/audit/hdfs/nn/ranger-plugin-audit.log /var/log/Bigdata/audit/hdfs/dn/hdfs-audit-datanode.log /var/log/Bigdata/audit/hdfs/jn/hdfs-audit-journalnode.log /var/log/Bigdata/audit/hdfs/zkfc/hdfs-audit-zkfc.log /var/log/Bigdata/audit/hdfs/httpfs/hdfs-audit-httpfs.log /var/log/Bigdata/audit/hdfs/router/hdfs-audit-router.log
Hive	/var/log/Bigdata/audit/hive/hiveserver/hive-audit.log /var/log/Bigdata/audit/hive/hiveserver/hive-rangeraudit.log /var/log/Bigdata/audit/hive/metastore/metastore-audit.log /var/log/Bigdata/audit/hive/webhcat/webhcat-audit.log
Hue	/var/log/Bigdata/audit/hue/hue-audits.log
Kafka	/var/log/Bigdata/audit/kafka/audit.log
Loader	/var/log/Bigdata/loader/audit/default.audit
MapReduce	/var/log/Bigdata/audit/mapreduce/jobhistory/mapred-audit-jobhistory.log
Oozie	/var/log/Bigdata/audit/oozie/oozie-audit.log
Spark	/var/log/Bigdata/audit/spark/jdbcserver/jdbcserver-audit.log /var/log/Bigdata/audit/spark/jdbcserver/ranger-audit.log /var/log/Bigdata/audit/spark/jobhistory/jobhistory-audit.log
Yarn	/var/log/Bigdata/audit/yarn/rm/yarn-audit-resourcemanager.log /var/log/Bigdata/audit/yarn/rm/ranger-plugin-audit.log /var/log/Bigdata/audit/yarn/nm/yarn-audit-nodemanager.log
ZooKeeper	/var/log/Bigdata/audit/zookeeper/quorumpeer/zk-audit-quorumpeer.log
MOTService	/var/log/Bigdata/motservice/DB/omm/pg_audit/dn_6001
RTDService	/var/log/Bigdata/rtd/rtdservice/RTDService_audit.log
Containers	/var/log/Bigdata/tomcat/container/web_container_audit.log
Doris	/var/log/Bigdata/audit/doris/fe/fe.audit.log

10.10.2 Manager Log List

Log Description

Log path: The default storage path of Manager log files is **/var/log/Bigdata/***Manager component*.

- ControllerService: **/var/log/Bigdata/controller/** (OMS installation and run logs)
- HTTPd: **/var/log/Bigdata/httpd** (HTTPd installation and run logs)
- Logman: **/var/log/Bigdata/logman** (log packaging tool logs)
- NodeAgent: **/var/log/Bigdata/nodeagent** (NodeAgent installation and run logs)
- okerberos: **/var/log/Bigdata/okerberos** (okerberos installation and run logs)
- oldapserver: **/var/log/Bigdata/oldapserver** (oldapserver installation and run logs)
- MetricAgent: **/var/log/Bigdata/metric_agent** (MetricAgent run logs)
- OMM: **/var/log/Bigdata/omm** (OMM installation and run logs)
- Timestamp: **/var/log/Bigdata/timestamp** (NodeAgent startup time logs)
- Tomcat: **/var/log/Bigdata/tomcat** (Web process logs)
- Upgrade: **/var/log/Bigdata/upgrade** (OMS upgrade logs)
- UpdateService: **/var/log/Bigdata/update-service** (upgrade service logs)
- Sudo: **/var/log/Bigdata/sudo** (sudo script execution logs)
- OS: **/var/log/***message file* (OS system logs)
- OS performance: **/var/log/osperf** (OS performance statistics logs)
- OS statistics: **/var/log/osinfo/statistics** (OS parameter configuration logs)

Log archive rule:

The automatic compression and archiving function is enabled for Manager logs. By default, when the size of a log file exceeds 10 MB, the log file is automatically compressed. The naming rule of a compressed log file is as follows: <*Original log name*>-<*yyyy-mm-dd_hh-mm-ss*>.[*ID*].**log.zip** A maximum of 20 latest compressed files are retained.

Table 10-67 Manager logs

Log Type	Log File Name	Description
Controller run logs	controller.log	Log file that records component installation, upgrade, configuration, monitoring, alarm reporting, and routine O&M operations
	controller_client.log	Run log file of the Representational State Transfer (REST) APIs

Log Type	Log File Name	Description
	acs.log	ACS run log file
	acs_spnego.log	spnego user logs in ACS
	aos.log	AOS run log file
	plugin.log	AOS plug-in logs
	backupplugin.log	Run log file that records the backup and restoration operations
	controller_config.log	Configuration run log file
	controller_nodesetup.log	Controller loading task log file
	controller_root.log	System log file of the Controller process
	controller_trace.log	Log file that records the remote procedure call (RPC) communication between Controller and NodeAgent
	controller_monitor.log	Monitoring log file
	controller_fsm.log	State machine log file
	controller_alarm.log	Controller alarm log file
	controller_backup.log	Controller backup and recovery log file
	install.log, restore_package.log, installPack.log, distributeAdapterFiles.log, and install_os_optimization.log	OMS installation log files
	oms_ctl.log	OMS startup and stop log file
	preInstall_client.log	Preprocessing log file before client installation
	installntp.log	NTP installation log file
	modify_manager_param.log	Manager parameter modification log file

Log Type	Log File Name	Description
	backup.log	OMS backup script run log file
	supressionAlarm.log	Alarm script run log file
	om.log	OM certificate generation log file
	backupplugin_ctl.log	Startup log file of the backup and restoration plug-in process
	getLogs.log	Run log of the log collection script
	backupAuditLogs.log	Run log of the audit log backup script
	certStatus.log	Log file that records regular certificate checks
	distribute.log	Certificate distribution log
	ficertgenetrate.log	Certificate replacement log file, covering level-2 certificates, CAS certificates, and HTTPd certificates
	genPwFile.log	Log file that records the generation of certificate password files
	modifyproxyconf.log	Log file that records the modification of the HTTPd proxy configuration
	importTar.log	Log file that records the process for importing certificates into the trust store.
HTTPd	install.log	HTTPd installation log file
	access_log, error_log	HTTPd run log file
Logman	logman.log	Log packaging tool log file

Log Type	Log File Name	Description
NodeAgent	install.log and install_os_optimization.log	NodeAgent installation log file
	installntp.log	NTP installation log file
	start_ntp.log	NTP startup log file
	ntpChecker.log	NTP check log file
	ntpMonitor.log	NTP monitoring log file
	heartbeat_trace.log	Log file that records heartbeats between NodeAgent and Controller
	alarm.log	Alarm log file
	monitor.log	Monitoring log file
	nodeagent_ctl.log and start-agent.log	NodeAgent startup log file
	agent.log	NodeAgent run log file
	cert.log	Certificate log file
	agentplugin.log	Log file that records the Agent plug-in running status
	omaplugin.log	OMA plug-in run log file
	diskhealth.log	Disk health check log file
	supressionAlarm.log	Alarm script run log file
	updateHostFile.log	Host list update log file
	collectLog.log	Run log file of the node log collection script
	host_metric_collect.log	Run log file of host metric collection
	checkfileconfig.log	Run log file of file permission check
	entropycheck.log	Entropy check run log file
	timer.log	Log file of scheduled node scheduling

Log Type	Log File Name	Description
	pluginmonitor.log	Component monitoring plug-in log file
	agent_alarm_py.log	Log file that records alarms upon insufficient NodeAgent file permission
	checkUserThread.log	User thread usage alarm collection log file
oKerberos	addRealm.log and modifyKerberosRealm.log	Realm handover log file
	checkservice_detail.log	Okerberos health check log file
	genKeytab.log	keytab generation log file
	KerberosAdmin_genConfigDetail.log	Run log file of **kadmin.conf** generated during start of the kadmin process
	KerberosServer_genConfigDetail.log	Run log file of **krb5kdc.conf** generated during start of the krb5kdc process
	oms-kadmind.log	Run log file of the kadmin process
	oms_kerberos_install.log and postinstall_detail.log	Okerberos installation log file
	oms-krb5kdc.log	Run log file of the krbkdc process
	start_detail.log	Okerberos startup log file
	realmDataConfigPro-cess.log	Log file that records the rollback upon a realm handover failure
	stop_detail.log	Okerberos stop log file
oldapserver	ldapserver_backup.log	Oldapserver backup log file
	ldapserver_chk_service.log	Oldapserver health check log file

Log Type	Log File Name	Description
	ldapserver_install.log	Oldapserver installation log file
	ldapserver_start.log	Oldapserver startup log file
	ldapserver_status.log	Log file that records the status of the Oldapserver process
	ldapserver_stop.log	Oldapserver stop log file
	ldapserver_wrap.log	Oldapserver service management log file
	ldapserver_uninstall.log	Oldapserver uninstallation log file
	restart_service.log	Oldapserver restart log file
	ldapserver_unlockUser.log	Log file that records information about unlocking LDAP users and managing accounts
metric_agent	gc.log	MetricAgent JVM GC log file
	metric_agent.log	Run log file of MetricAgent
	metric_agent_qps.log	Log file that records MetricAgent Internal queue length and QPS information
	metric_agent_root.log	All run log files of MetricAgent
	start.log	Log file that records information about the MetricAgent startup and stop
OMM	omsconfig.log	OMS configuration log file
	check_oms_heartbeat.log	OMS heartbeat log file
	monitor.log	OMS monitoring log file
	ha_monitor.log	HA_Monitor operation log file
	ha.log	HA operation log file

Log Type	Log File Name	Description
	fms.log	Alarm log file
	fms_ha.log	HA alarm monitoring log file
	fms_script.log	Alarm control log file
	config.log	Alarm configuration log file
	iam.log	IAM log file
	iam_script.log	IAM control log file
	iam_ha.log	IAM HA monitoring log file
	config.log	IAM configuration log file
	operatelog.log	IAM operation log file
	heartbeatcheck_ha.log	OMS heartbeat HA monitoring log file
	install_oms.log	OMS installation log file
	pms_ha.log	HA monitoring log file
	pms_script.log	Monitoring control log file
	config.log	Monitoring configuration log file
	plugin.log	Monitoring plug-in run log file
	pms.log	Monitoring log file
	ha.log	HA run log file
	omm_gaussdba.log	GaussDB HA monitoring log file
	gaussdb-<SERIAL>.log	GaussDB run log file
	gs_ctl-<DATE>.log	Archive log file of GaussDB control logs
	gs_ctl-current.log	GaussDB control log file
	gs_guc-current.log	GaussDB operation log file
	encrypt.log	OMM encryption log file

Log Type	Log File Name	Description
	omm_agent_ctl.log	OMA control log file
	oma_monitor.log	OMA monitoring log file
	install_oma.log	OMA installation log file
	config_oma.log	OMA configuration log file
	omm_agent.log	OMA run log file
	acs.log	ACS resource log file
	aos.log	AOS resource log file
	controller.log	Controller resource log file
	floatip.log	Floating IP address resource log file
	ha_ntp.log	NTP resource log file
	httpd.log	HTTPd resource log file
	okerberos.log	Okerberos resource log file
	oldap.log	OLdap resource log file
	tomcat.log	Tomcat resource log file
	send_alarm.log	Run log file of the HA alarm sending script of the management node
	pms_gc_<DATE>.log	Monitoring GC log file
	pms_jstack.log	Monitoring stack log file
Timestamp	restart_stamp	NodeAgent startup time log file
Tomcat	cas.log and localhost_access_cas_log.log	CAS run log file
	catalina.log, catalina.out, host-manager.log, localhost.log, and manager.log	Tomcat run log file
	localhost_access_web_log.log	Log file that records the access to REST APIs of FusionInsight Manager

Log Type	Log File Name	Description
	web.log	Run log file of the Web process
	northbound_ftp_sftp.log, snmp.log	Northbound log file
	perfStats.log	Performance statistics log file
	redis_script.log	Redis script run log file
	web_redis.log	Run log file of Redis-ws
update-service	omm_upd_server.log	UPDServer run log file
	omm_upd_agent.log	UPDAgent run log file
	update-manager.log	UPDManager run log file
	install.log	Installation log file of the upgrade service
	uninstall.log	Uninstallation log file of the upgrade service

Log Type	Log File Name	Description
	catalina.<*Time*>.log, catalina.out, host-manager.<*Time*>.log, localhost.<*Time*>.log, manager.<*Time*>.log, manager_access_log.<*Time*>.txt, web_service_access_log.<*Time*>.txt, catalina.log, gc-update-service.log.0.current, update-manager.controller, update-web-service.controller, update-web-service.log, commit_rm_distributed.log, commit_rm_upload_package.log, common_omagent_operator.log, forbid_monitor.log, initialize_package_atoms.log, initialize_unzip_pack.log, omm-upd.log, register_patch_pack.log, resume_monitor.logrollback_clear_patch.log, unregister_patch_pack.log, update-rcommupd.log, update-rcupdatemanager.log, and update-service.log	Run log file of the upgrade service
Upgrade	upgrade.log_<*Time*>	OMS upgrade log file
	rollback.log_<*Time*>	OMS rollback log file
sudo	sudo.log	Sudo script execution log file

Log Levels

Table 10-68 describes the log levels provided by Manager. The log levels are FATAL, ERROR, WARN, INFO, and DEBUG in descending order. Logs whose levels are higher than or equal to the set level are printed by the program. The number of printed logs decreases as the set log level increases.

Table 10-68 Log levels

Level	Description
FATAL	Logs of this level record fatal error information about the current event processing that may result in a system crash.
ERROR	Logs of this level record error information about the current event processing, which indicates that system running is abnormal.
WARN	Logs of this level record abnormal information about the current event processing. These abnormalities will not result in system faults.
INFO	Logs of this level record normal running status information about the system and events.
DEBUG	Logs of this level record system information and debugging information.

Log Formats

The following table lists the Manager log formats.

Table 10-69 Log formats

Log Type	Component	Format	Example
Controller, HTTPd, Logman, NodeAgent, oKerberos, oldapserver, OMM, Tomcat, and upgrade	Controller, HTTPd, Logman, NodeAgent, oKerberos, oldapserver, OMM, Tomcat, and upgrade	<yyyy-MM-dd HH:mm:ss, SSS>|<Log Level>|<*Name of the thread for which the log is generated*>|<*Log message*>|<*Location where the log event occurs*>	2020-06-30 00:37:09,067 INFO [pool-1-thread-1] Completed Discovering Node. com.xxx.hadoop.om.controller.tasks.nodesetup.DiscoverNodeTask.execute(DiscoverNodeTask.java:299)

10.10.3 Configuring the Log Level and Log File Size

Scenario

You can change the log levels of FusionInsight Manager. For a specific service, you can change the log level and the log file size to prevent the failure in saving logs due to insufficient disk space.

Impact on the System

The services need to be restarted for the new configuration to take effect. During the restart, the services are unavailable.

Changing the FusionInsight Manager Log Level

1. Log in to the active management node as user **omm**.
2. Run the following command to switch to the required directory:

   cd ${BIGDATA_HOME}/om-server/om/sbin
3. Run the following command to change the log level:

   ./setLogLevel.sh*Log level parameters*

   The priorities of log levels are FATAL, ERROR, WARN, INFO, and DEBUG in descending order. Logs whose levels are higher than or equal to the set level are printed. The number of printed logs decreases as the configured log level increases.

   - **DEFAULT**: After this parameter is set, the default log level is used.
   - **FATAL**: critical error log level. After this parameter is set, only logs of the **FATAL** level are printed.
   - **ERROR**: error log level. After this parameter is set, logs of the **ERROR** and **FATAL** levels are printed.
   - **WARN**: warning log level. After this parameter is set, logs of the **WARN**, **ERROR**, and **FATAL** levels are printed.
   - **INFO** (default): informational log level. After this parameter is set, logs of the **INFO**, **WARN**, **ERROR**, and **FATAL** levels are printed.
   - **DEBUG**: debugging log level. After this parameter is set, logs of the **DEBUG**, **INFO**, **WARN**, **ERROR**, and **FATAL** levels are printed.
   - **TRACE**: tracing log level. After this parameter is set, logs of the **TRACE**, **DEBUG**, **INFO**, **WARN**, **ERROR**, and **FATAL** levels are printed.

   NOTE

   The log levels of components are different from those defined in open-source code.
4. Download and view logs to verify that the log level settings have taken effect. For details, see **Log**.

Changing the Service Log Level and Log File Size

NOTE

KrbServer, LdapServer, and DBService do not support the changing of service log levels and log file sizes.

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services**.

Step 3 Click a service in the service list. On the displayed page, click the **Configuration** page.

Step 4 On the displayed page, click the **All Configuration** tab. Expand the role instance displayed on the left of the page. Click **Log** of the role to be modified.

Step 5 Search for each parameter and obtain the parameter description. On the parameter configuration page, select the required log level or change the log file size. The unit of the log file size is MB.

NOTICE

- The system automatically deletes logs based on the configured log size. To save more information, set the log file size to a larger value. To ensure the integrity of log files, you are advised to manually back up the log files to another directory based on the actual service volume before the log files are cleared according to clearance rules.
- Some services do not support change of the log level on the UI.

Step 6 Click **Save**. In the **Save Configuration** dialog box, click **OK**.

Step 7 Download and view logs to verify that the log level settings have taken effect.

----End

10.10.4 Configuring the Number of Local Audit Log Backups

Scenario

Audit logs of cluster components are classified by name and stored in the **/var/log/Bigdata/audit** directory on each cluster node. The OMS automatically backs up the audit log directories at 03:00 every day.

The audit log directory on each node is compressed and named in the *<Node IP address>***.tar.gz** format. All compressed files are compressed and named in the *<yyyy-MM-dd_HH-mm-ss>***.tar.gz** format and saved in the **/var/log/Bigdata/audit/bk/** directory on the active management node. In addition, the standby management node saves a copy of the file.

By default, a maximum of 90 OMS backup files can be retained. This section describes how to configure the maximum number.

Procedure

Step 1 Log in to the active management node as user **omm**.

NOTE

Perform this operation only on the active management node. This operation is not supported on the standby management nodes; otherwise, the cluster cannot work properly.

Step 2 Run the following command to switch to the required directory:

cd ${BIGDATA_HOME}/om-server/om/sbin

Step 3 Run the following command to change the maximum number of audit log backup files to be retained:

./modifyLogConfig.sh -m ***Maximum number of backup files that can be retained***

The default value is **90**. The value ranges from **0** to **365**. A larger value means to consume more disk space.

If the following information is displayed, the operation is successful:

```
Modify log config successfully
```

----End

10.10.5 Viewing Role Instance Logs

Scenario

FusionInsight Manager allows users to view logs of each role instance.

Procedure

Step 1 Log in to FusionInsight Manager.

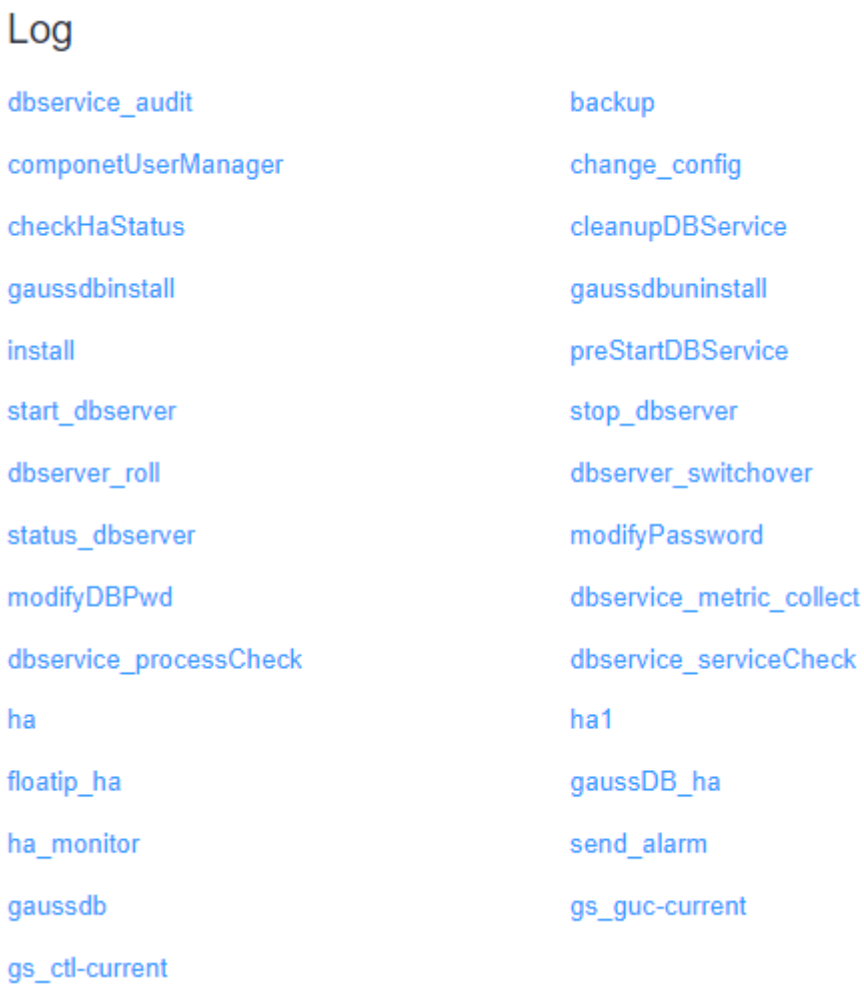
Step 2 Choose **Cluster** > **Services**, and click a service name. Then click the **Instances** tab of the service and click the name of the target instance to access the instance status page.

Step 3 In the **Log** area, click the name of a log file to preview its content online.

NOTE

- On the **Hosts** page, click a host name. In the instance list of the host, you can view the log files of all role instances on the host.
- By default, a maximum of 100 lines of logs can be displayed. You can click **Load More** to view more logs. Click **Download** to download the log file to the local PC. For details about how to download service logs in batches, see **Log Download**.

Figure 10-17 Viewing instance logs



----End

10.11 Backup and Recovery Management

10.11.1 Introduction

Overview

FusionInsight Manager provides the backup and restoration of system data and user data by component. The system can back up Manager data, component metadata, and service data.

Data can be backed up to local disks (LocalDir), local HDFS (LocalHDFS), remote HDFS (RemoteHDFS), NAS (NFS/CIFS), Object Storage Service (OBS), and SFTP server (SFTP). For details, see **Backing Up Data**.

For a component that supports multiple services, multiple instances of a service can be backed up and restored. The backup and restoration operations are consistent with those of a service instance.

Backup and restoration tasks are performed in the following scenarios:

- Routine backup is performed to ensure the data security of the system and components.
- If the system is faulty, the data backup can be used to recover the system.
- If the active cluster is completely faulty, a mirrored cluster identical to the active cluster needs to be created. You can use the backup data to restore the active cluster.

Table 10-70 Manager configuration data to be backed up

Backup Type	Backup Content	Backup Directory Type
OMS	Database data (excluding alarm data) and configuration data in the cluster management system by default	• LocalDir • LocalHDFS • RemoteHDFS • NFS • CIFS • SFTP • OBS

Table 10-71 Component metadata or other data to be backed up

Backup Type	Backup Content	Backup Directory Type
DBService	Metadata of the components (including Loader, Metadata, Hive, Spark, Oozie, CDL, Redis, and Hue) managed by DBService. For a cluster with multiple services installed, back up the metadata of multiple Hive and Spark service instances.	• LocalDir • LocalHDFS • RemoteHDFS • NFS • CIFS • SFTP • OBS
Flink	Flink metadata.	• LocalDir • LocalHDFS • RemoteHDFS
Kafka	Kafka metadata.	• LocalDir • LocalHDFS • RemoteHDFS • NFS • CIFS • OBS

Backup Type	Backup Content	Backup Directory Type
NameNode	HDFS metadata. After multiple NameServices are added, backup and restoration are supported for all of them and the operations are consistent with those of the default hacluster instance.	• LocalDir • RemoteHDFS • NFS • CIFS • SFTP • OBS
Yarn	Information about the Yarn service resource pool.	
HBase	**tableinfo** files and data files of HBase system tables.	
Solr	Solr metadata.	• LocalDir • LocalHDFS • NFS • CIFS • SFTP
Elasticsearch	Elasticsearch metadata, that is, data related to Elasticsearch security functions in ZooKeeper.	• LocalDir • RemoteHDFS • NFS • CIFS
Redis	Redis service data.	• LocalHDFS
IoTDB	IoTDB metadata.	• LocalDir • NFS • RemoteHDFS • CIFS • SFTP
ClickHouse	ClickHouse metadata.	• LocalDir • RemoteHDFS • OBS
Containers	Containers metadata.	• LocalDir • LocalHDFS • RemoteHDFS
RTDService	RTDService metadata.	• LocalDir • LocalHDFS • RemoteHDFS

Table 10-72 Service data of specific components to be backed up

Backup Type	Backup Content	Backup Directory Type
HBase	Table-level user data. For a cluster with multiple services installed, backup and restoration are supported for multiple HBase service instances and the backup and restoration operations are consistent with those of a single HBase service instance.	• RemoteHDFS • NFS • CIFS • SFTP • OBS
HDFS	Directories or files of user services. **NOTE** Encrypted directories cannot be backed up or restored.	• RemoteHDFS • NFS • CIFS • SFTP
Hive	Table-level user data. For a cluster with multiple services installed, backup and restoration are supported for multiple Hive service instances and the backup and restoration operations are consistent with those of a single Hive service instance.	
Elasticsearch	Index data. For a cluster with multiple services installed, backup and restoration are supported for multiple Elasticsearch service instances and the backup and restoration operations are consistent with those of a single Elasticsearch service instance.	• RemoteHDFS • NFS
Solr	Index data. For a cluster with multiple services installed, backup and restoration are supported for multiple Solr service instances and the backup and restoration operations are consistent with those of a single Solr service instance.	• RemoteHDFS
IoTDB	IoTDB service data.	• RemoteHDFS
ClickHouse	Table-level user data.	• RemoteHDFS • OBS
MOTService	MOTService service data.	• RemoteHDFS

Note that some components do not provide data backup or restoration:

- Kafka supports replicas and allows multiple replicas to be specified when a topic is created.
- CDL data is stored in DBService and Kafka. A system administrator can create DBService and Kafka backup tasks to back up data.

- MapReduce and Yarn data is stored in HDFS. Therefore, they rely on the backup and restoration provided by HDFS.
- Backup and restoration of service data in ZooKeeper are performed by their own upper-layer components.

Principles

Task

Before backup or restoration, you need to create a backup or restoration task and set task parameters, such as the task name, backup data source, and type of the directory for storing backup files. Then you can execute the tasks to back up or restore data. When Manager is used to restore the data of HDFS, HBase, Elasticsearch, Hive, and NameNode, the cluster cannot be accessed.

Each backup task can back up data of different data sources and generate an independent backup file for each data source. All the backup files generated in a backup task form a backup file set, which can be used in restoration tasks. Backup data can be stored on Linux local disks, local cluster HDFS, and standby cluster HDFS.

Backup tasks support full backup and incremental backup policies. Cloud data backup tasks do not support incremental backup. If the backup directory type is NFS or CIFS, incremental backup is not recommended. When incremental backup is used for NFS or CIFS backup, the latest full backup data is updated each time the incremental backup is performed. Therefore, no new recovery point is generated.

NOTE

Task execution rules:

- If a task is being executed, the task cannot be executed repeatedly and other tasks cannot be started at the same time.
- The interval at which a periodic task is automatically executed must be greater than 120s. Otherwise, the task is postponed and will be executed in the next period. Manual tasks can be executed at any interval.
- When a periodic task is to be automatically executed, the current time cannot be 120s later than the task start time. Otherwise, the task is postponed and executed in the next period.
- When a periodic task is locked, it cannot be automatically executed and needs to be manually unlocked.
- Before an OMS, DBService, Kafka, MOTService, or NameNode backup task starts, ensure that the LocalBackup partition on the active management node has not less than 20 GB of available space. Otherwise, the backup task cannot be started.

When planning backup and restoration tasks, select the data to be backed up or restored strictly based on the service logic, data store structure, and database or table association. By default, the system creates periodic backup tasks **default-oms** and **default-*cluster ID*** at an interval of one hour. OMS metadata and cluster metadata, such as DBService and NameNode, can be fully backed up to local disks.

Snapshot

The system uses the snapshot technology to quickly back up data. Snapshots include HBase, Elasticsearch, and HDFS snapshots.

- HBase snapshots

  An HBase snapshot is a backup file of HBase tables at a specified time point. This backup file does not replicate service data or affect the RegionServer. The HBase snapshot replicates table metadata, including table descriptor, region info, and HFile reference information. The metadata can be used to restore data before the snapshot creation time.

- HDFS snapshots

  An HDFS snapshot is a read-only backup of HDFS at a specified time point. The snapshot is used in data backup, misoperation protection, and disaster recovery scenarios.

  The snapshot function can be enabled for any HDFS directory to create the related snapshot file. Before creating a snapshot for a directory, the system automatically enables the snapshot function for the directory. Creating a snapshot does not affect any HDFS operation. A maximum of 65,536 snapshots can be created for each HDFS directory.

  When a snapshot is being created for an HDFS directory, the directory cannot be deleted or modified before the snapshot is created. Snapshots cannot be created for the upper-layer directories or subdirectories of the directory.

- Elasticsearch snapshots

  An Elasticsearch snapshot uses the index data policy (snapshot API) of the backup cluster provided by Elasticsearch. The status and data of the current cluster at a specified time are backed up and saved to a specified snapshot repository. Your first snapshot will be a complete copy of data, and all subsequent snapshots will save the differences between the existing snapshots and the new data.

DistCp

Distributed copy (DistCp) is a tool used to replicate a large amount of data in HDFS in a cluster or between the HDFSs of different clusters. In a backup or restoration task of HBase, HDFS, or Hive, if you back up the data to HDFS of the standby cluster, the system invokes DistCp to perform the operation. Install the MRS software of the same version for the active and standby clusters and install the cluster.

DistCp uses MapReduce to implement data distribution, troubleshooting, restoration, and report. DistCp specifies different Map jobs for various source files and directories in the specified list. Each Map job copies the data in the partition that corresponds to the specified file in the list.

If you use DistCp to replicate data between HDFSs of two clusters, configure the cross-cluster mutual trust (mutual trust does not need to be configured for clusters managed by the same FusionInsight Manager) and cross-cluster replication for both clusters. When backing up the cluster data to HDFS in another cluster, you need to install the Yarn component. Otherwise, the backup fails.

Local rapid restoration

After using DistCp to back up the HBase, HDFS, and Hive data of the local cluster to the HDFS of the standby cluster, the HDFS of the local cluster retains the backup data snapshots. You can create local rapid restoration tasks to restore data by using the snapshot files in the HDFS of the local cluster.

NAS

Network Attached Storage (NAS) is a dedicated data storage server which includes the storage components and embedded system software. It provides the cross-platform file sharing function. By using NFS (supporting NFSv3 and NFSv4) and CIFS (supporting SMBv2 and SMBv3), you can connect the service plane of MRS to the NAS server to back up data to the NAS or restore data from the NAS.

NOTE

- Before data is backed up to the NAS, the system automatically mounts the NAS shared address to a local partition of the backup task execution node. After the backup is complete, the system unmounts the NAS shared partition from the backup task execution node.
- To prevent backup and restoration failures, do not access the shared address where the NAS server has been mounted to, for example, **/srv/BigData/LocalBackup/nas**, during data backup and restoration.
- When service data is backed up to the NAS, DistCp is used.

Specifications

Table 10-73 Specifications of the backup and restoration feature

Item	Specification
Maximum number of backup or restoration tasks	100
Number of concurrent tasks in a cluster	1
Maximum number of waiting tasks	199
Maximum size (GB) of backup files on a Linux local disk	600

NOTE

If service data is stored in the ZooKeeper upper-layer components, ensure that the number of znodes in a single backup or restoration task is not too large. Otherwise, the task will fail, and the ZooKeeper service performance will be affected. To check the number of znodes in a single backup or restoration task, perform the following operations:

- Ensure that the number of znodes in a single backup or restoration task is smaller than the upper limit of OS file handles. Specifically:
  1. To check the upper limit at the system level, run the **cat /proc/sys/fs/file-max** command.
  2. To check the upper limit at the user level, run the **ulimit -n** command.
- If the number of znodes in the parent directory exceeds the upper limit, back up and restore data in its sub-directories in batches. To check the number of znodes using ZooKeeper client scripts, perform the following operations:
  1. On **Homepage** of FusionInsight Manager, choose **Cluster** > **Services** > **ZooKeeper**. Click **Instance** and view the management IP address of each ZooKeeper role instance.
  2. Log in to the node where the client is located and run the following command:

     zkCli.sh -server *ip*:*port*, where, *ip* can be any management IP address, and the default port number is 2181.
  3. If the following information is displayed, login to the ZooKeeper server is successful:
     ```
     WatchedEvent state:SyncConnected type:None path:null
     [zk: ip:port(CONNECIED) 0]
     ```
  4. Run the **getusage** command to check the number of znodes in the directory to be backed up.

     For example, **getusage /hbase/region**. In the command output, **Node count=xxxxxx** indicates the number of znodes stored in the **region** directory.

Table 10-74 Specifications of the default task

Item	OMS	Elasticsearch	HBase	IoTDB	ClickHouse	Kafka	DBService	Flink	NameNode
Backup period	1 hour								
Maximum number of backups	168 (7-day historical data)								24 (one-day historical data)
Maximum size of a backup file	10 MB	20 MB	10 MB	10 MB	20 MB	512 MB	100 MB	1 GB	20 GB
Maximum size of disk space used	1.64 GB	3.28 GB	1.64 GB	1.64 GB	3.28 GB	84 GB	16.41 GB	168 GB	480 GB
Storage path of backup data	*Data storage path*/**LocalBackup/** of the active and standby management nodes								

NOTE

- When periodic backup is performed for HDFS, Hive, Elasticsearch, and HBase, snapshots are created for protected directories. Affected by the snapshot mechanism, deleting data between two backups does not release disk space immediately.
- The backup data of the default backup task must be periodically transferred and saved outside the cluster based on the enterprise O&M requirements.
- Administrators can create DistCp backup tasks to save OMS, DBService, and NameNode data to external clusters.
- The execution time of a cluster data backup task can be calculated using the following formula: Task execution time = Volume of data to be backed up/Network bandwidth between the cluster and the backup device. In practice, you are advised to multiply the calculated time by 1.5 to get the reference value of the task execution time.
- Executing a data backup task affects the maximum I/O performance of the cluster. Therefore, you are advised to execute a backup task during off-peak hours.

10.11.2 Backing Up Data

10.11.2.1 Backing Up Manager Data

Scenario

To ensure data security of FusionInsight Manager routinely or before and after a critical operation (such as capacity expansion and reduction) on FusionInsight Manager, you need to back up FusionInsight Manager data. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up Manager data. Both automatic and manual backup tasks are supported.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.
- If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- The backup type, period, policy, and other specifications have been planned based on the service requirements and you have checked whether *Data storage path*/**LocalBackup/** has sufficient space on the active and standby management nodes.
- If you want to back up data to NAS, you have deployed the NAS server in advance.

- If you want to back up data to OBS, you have connected the current cluster to OBS and have the permission to access OBS.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Set **Backup Object** to **OMS**.

Step 5 Set **Mode** to the type of the backup task.

Periodic indicates that the backup task is executed by the system periodically. **Manual** indicates that the backup task is executed manually.

Table 10-75 Periodic backup parameters

Parameter	Description
Started	Indicates the time when the task is started for the first time.
Period	Indicates the task execution interval. The options include **Hours** and **Days**.
Backup Policy	• **Full backup at the first time and incremental backup subsequently** • **Full backup every time** • **Full backup once every n times** **NOTE** • Incremental backup is not supported when Manager data and component metadata are backed up. Only **Full backup every time** is supported. • If **Path Type** is set to **NFS** or **CIFS**, incremental backup cannot be used. When incremental backup is used for NFS or CIFS backup, the latest full backup data is updated each time the incremental backup is performed. Therefore, no new recovery point is generated.

Step 6 In **Configuration**, select **OMS**.

Step 7 Set **Path Type** of **OMS** to a backup directory type.

The following backup directory types are supported:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node and the standby management node automatically synchronizes the backup files.

  The default storage directory is *Data storage path*/**LocalBackup/**, for example, **/srv/BigData/LocalBackup**.

  If you select this option, you need to set the maximum number of replicas to specify the number of backup file sets that can be retained in the backup directory.

- **LocalHDFS**: indicates that the backup files are stored in the HDFS directory of the current cluster.

  If you select this option, set the following parameters:

  - **Target Path**: indicates the HDFS directory for storing the backup files. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Cluster for Backup**: Enter the cluster name mapping to the backup directory.
  - **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select this option, set the following parameters:

  - **Destination NameService Name**: indicates the NameService name of the standby cluster. You can set it to the NameService name (**haclusterX**, **haclusterX1**, **haclusterX2**, **haclusterX3**, or **haclusterX4**) of the built-in remote cluster of the cluster, or the NameService name of a configured remote cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Target NameNode IP Address**: indicates the IP address of the NameNode service plane in the standby cluster. It can be of an active or standby node.
  - **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Source Cluster**: Select the cluster of the Yarn queue used by the backup data.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the source cluster.

- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol.

  If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)

  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
- **CIFS**: indicates that backup files are stored in the NAS using the CIFS protocol.

  If you select this option, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select this option, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the server where the backup data is stored.
  - **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
  - **Username**: indicates the username for connecting to the server using the SFTP protocol.
  - **Password**: indicates the password for connecting to the server using the SFTP protocol.
  - **Server Shared Path**: indicates the backup path on the SFTP server.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
- **OBS**: indicates that backup files are stored in OBS.

  If you select this option, set the following parameters:
  - **Target Path**: indicates the OBS directory for storing backup data.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

Step 8 Click **OK**.

Step 9 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Task creation time*, and the subdirectory is used to save data source backup files.

The format of the backup file name is *Version_Data source_Task execution time*.**tar.gz**.

----End

10.11.2.2 Backing Up CDL Data

Scenario

To ensure CDL service data security routinely or before a major operation on CDL (such as upgrade or migration), you need to back up CDL data. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

CDL data is stored in DBService and Kafka. You can create DBService and Kafka backup tasks on FusionInsight Manager to back up CDL data. Both automatic and manual backup tasks are supported.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.
- If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- The backup type, period, policy, and other specifications have been planned based on the service requirements and you have checked whether *Data storage path*/**LocalBackup/** has sufficient space on the active and standby management nodes.
- If you want to back up data to NAS, you have deployed the NAS server in advance.
- If you want to back up data to OBS, you have connected the current cluster to OBS and have the permission to access OBS.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task.

Periodic indicates that the backup task is executed by the system periodically. **Manual** indicates that the backup task is executed manually.

Table 10-76 Periodic backup parameters

Parameter	Description
Started	Indicates the time when the task is started for the first time.
Period	Indicates the task execution interval. The options include **Hours** and **Days**.
Backup Policy	• **Full backup at the first time and incremental backup subsequently** • **Full backup every time** • **Full backup once every n times** **NOTE** • Incremental backup is not supported when Manager data and component metadata are backed up. Only **Full backup every time** is supported. • If **Path Type** is set to **NFS** or **CIFS**, incremental backup cannot be used. When incremental backup is used for NFS or CIFS backup, the latest full backup data is updated each time the incremental backup is performed. Therefore, no new recovery point is generated.

Step 6 Set **Configuration** to **DBService** and **Kafka**.

NOTE

If there are multiple DBService or Kafka services, all DBService or Kafka services are backed up by default. You can click **Assign Service** to specify the services to be backed up.

Step 7 Set **Path Type** of **DBService** to a backup directory type. For details about how to set the parameters, see **Step 7**.

Step 8 Set **Path Type** of **Kafka** to a backup directory type. For details about how to set the parameters, see **Step 7**.

Step 9 Click **OK**.

Step 10 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Task creation time*, and the subdirectory is used to save data source backup files.

The format of the backup file name is *Version_Data source_Task execution time*.**tar.gz**.

----End

10.11.2.3 Backing Up Containers Metadata

Scenario

To ensure Containers metadata security or before a major operation on Containers (such as upgrade or migration), you need to back up Containers metadata. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up Containers metadata. Both automatic and manual backup tasks are supported.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.
- The backup type, period, policy, and other specifications have been planned based on the service requirements and you have checked whether *Data storage path*/**LocalBackup/** has sufficient space on the active and standby management nodes.
- If the active cluster is deployed in security mode (with Kerberos authentication enabled) and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust must be configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode (with Kerberos authentication disabled), mutual trust is not required.
- The time on the active and standby clusters must be the same, and the NTP service on the active and standby clusters uses the same time source.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task. **Periodic** indicates that the backup task is periodically executed. **Manual** indicates that the backup task is manually executed.

To create a periodic backup task, set the following parameters:

Table 10-77 Periodic backup parameters

Parameter	Description
Started	The time when the task is started for the first time.
Period	The task execution interval. Value options include **Hours** and **Days**.
Backup Policy	• **Full backup at the first time and incremental backup subsequently** • **Full backup every time** • **Full backup once every n times**

Step 6 In **Configuration**, select **Containers** under **Metadata and other data**.

Step 7 Set **Path Type** of **Containers** to a backup directory type.

The following backup directory types are supported:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node and the standby management node automatically synchronizes the backup files.

  The default storage directory is *Data storage path*/**LocalBackup/**, for example, **/srv/BigData/LocalBackup**.

  If you select this option, you need to set the maximum number of replicas to specify the number of backup file sets that can be retained in the backup directory.
- **LocalHDFS**: indicates that the backup files are stored in the HDFS directory of the current cluster.

  If you select this option, you also need to configure the following parameters:

  – **Target Path**: indicates the HDFS directory for storing the backup files. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.

  – **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

  – **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
- **RemoteHDFS**: indicates that backup files are stored in HDFS of the standby cluster.

  You also need to set the following parameters:

  – **Destination NameService Name**: indicates the NameService name of the standby cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster.

  – **IP Mode**: indicates the mode of the target IP address. The system automatically selects an IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.

  – **Destination Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster.

- **Destination Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster.
- **Destination NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the destination cluster.
- **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.

Step 8 Click **OK**.

Step 9 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Task creation time*, and the subdirectory is used to save data source backup files. The format of the backup file name is *Data source_Task execution time***.tar.gz**.

----End

10.11.2.4 Backing Up ClickHouse Metadata

Scenario

To ensure ClickHouse metadata security or before a major operation (such as upgrade or migration), you need to back up ClickHouse metadata. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up ClickHouse metadata. Both automatic and manual backup tasks are supported.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.
- The backup type, period, policy, and other specifications have been planned based on the service requirements and you have checked whether *Data storage path***/LocalBackup/** has sufficient space on the active and standby management nodes.
- If the active and standby clusters are deployed in security mode and they are not managed by the same FusionInsight Manager, mutual trust must be configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active and standby clusters are deployed in normal mode, no mutual trust is required.
- The time on the active and standby clusters must be the same, and the NTP service on the active and standby clusters uses the same time source.

- In the active/standby cluster, if data is remotely backed up to HDFS, ensure that the value of **HADOOP_RPC_PROTECTION** of ClickHouse is the same as that of **hadoop.rpc.protection** of HDFS.
- When data is remotely backed up to HDFS, HDFS encrypted directories are not supported.
- If you want to back up data to OBS, you have connected the current cluster to OBS and have the permission to access OBS.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task. **Periodic** indicates that the backup task is periodically executed. **Manual** indicates that the backup task is manually executed.

To create a periodic backup task, set the following parameters:

- **Started**: indicates the time when the task is started for the first time.
- **Period**: indicates the task execution interval. The options include **Hours** and **Days**.
- **Backup Policy**: Only **Full backup every time** is supported.

Step 6 In **Configuration**, select **ClickHouse** under **Metadata and other data**.

Step 7 Set **Path Type** of **ClickHouse** to a backup directory type.

Table 10-78 Path of backup data

Directory Type	Description
LocalDir	Indicates that the backup files are stored on the local disk of the active management node, and the standby management node automatically synchronizes the backup files. The default storage directory is *Data storage path*/**LocalBackup/**, for example, **/srv/BigData/LocalBackup**. If you select this option, you need to set the maximum number of replicas to specify the number of backup file sets that can be retained in the backup directory.

Directory Type	Description
RemoteHDFS	Indicates that the backup files are stored in the HDFS directory of the standby cluster. Only the latest backup file can be retained. Historical backup files are overwritten. You also need to configure the following parameters: • **Destination NameService Name**: indicates the NameService name of the standby cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster. • **IP Mode**: indicates the mode of the target IP address. The system automatically selects an IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**. • **Destination Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster. • **Destination Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster. • **Destination NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the destination cluster. • **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
OBS	Indicates that backup files are stored in an OBS directory. • **Target Path**: indicates the OBS directory for storing backup data. • **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

Step 8 Click **OK**.

Step 9 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Task creation time*, and the subdirectory is used to save data

source backup files. The format of the backup file name is *Data source_Task execution time*.**tar.gz**.

----End

10.11.2.5 Backing Up ClickHouse Service Data

Scenario

To ensure ClickHouse service data security routinely or before a major operation on ClickHouse (such as upgrade or migration), you need to back up ClickHouse service data. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up ClickHouse service data. Both automatic and manual backup tasks are supported.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.
- If the active and standby clusters are deployed in security mode and they are not managed by the same FusionInsight Manager, mutual trust must be configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active and standby clusters are deployed in normal mode, no mutual trust is required.
- The time on the active and standby clusters must be the same, and the NTP service on the active and standby clusters uses the same time source.
- You have planned the backup type, period, object, and directory based on service requirements.
- The HDFS in the standby cluster has sufficient space. You are advised to save backup files in a custom directory.
- In the active/standby cluster, if data is remotely backed up to HDFS, ensure that the value of **HADOOP_RPC_PROTECTION** of ClickHouse is the same as that of **hadoop.rpc.protection** of HDFS.
- When data is remotely backed up to HDFS, HDFS encrypted directories are not supported.
- If you want to back up data to OBS, you have connected the current cluster to OBS and have the permission to access OBS.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task.

Periodic indicates that the backup task is executed by the system periodically. **Manual** indicates that the backup task is executed manually.

Table 10-79 Periodic backup parameters

Parameter	Description
Started	The time when the task is started for the first time.
Period	The task execution interval. Value options include **Hours** and **Days**.
Backup Policy	• **Full backup at the first time and incremental backup subsequently** • **Full backup every time** • **Full backup once every n times** **NOTE** • Incremental backup is not supported when Manager data and component metadata are backed up. Only **Full backup every time** is supported.

Step 6 In **Configuration**, choose **Service Data** > **ClickHouse** > **ClickHouse**.

Step 7 Set **Path Type** of **ClickHouse** to a backup directory type.

Table 10-80 Path of backup data

Directory Type	Description
RemoteHDFS	Indicates that the backup files are stored in the HDFS directory of the standby cluster. Only the latest backup file can be retained. Historical backup files are overwritten. You also need to configure the following parameters: ● **Destination NameService Name**: indicates the NameService name of the standby cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster. ● **IP Mode**: indicates the mode of the target IP address. The system automatically selects an IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**. ● **Destination Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster. ● **Destination Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster. ● **Destination NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the destination cluster. ● **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
OBS	Indicates that backup files are stored in an OBS directory. ● **Target Path**: indicates the OBS directory for storing backup data. ● **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

Step 8 Set **Maximum Number of Recovery Points** to any value from **1** to **1000** because this parameter is not used by ClickHouse.

Step 9 Set **Backup Content** to one or multiple ClickHouse tables to be backed up.

You can select backup data using either of the following methods:

- Adding a backup data file
  a. Click **Add**.

b. Select the table to be backed up under **File Directory**, and click **Add** to add the table to **Backup Content**.

c. Click **OK**.

- Selecting using regular expressions

a. Click **Query Regular Expression**.

b. Enter the logical cluster and database to which the ClickHouse table belongs in the first text box as prompted. The logical cluster and database must match the existing logical cluster and database, for example, **/default_cluster/database**.

c. Enter a regular expression in the second box. Standard regular expressions are supported. For example, to search for all tables that contain the keyword **test** in the database, enter **test.***.

d. Click **Refresh** to view the displayed tables in **Directory Name**.

e. Click **Synchronize** to save the result.

NOTE

- When entering regular expressions, click + or − to add or delete an expression.
- If the selected table or directory is incorrect, click **Clear Selected Node** to deselect it.

Step 10 Click **Verify** to check whether the backup task is configured correctly.

The possible causes of the verification failure are as follows:

- The target NameNode IP address is incorrect.
- The directory or table to be backed up does not exist.
- The name of the NameService is incorrect.

Step 11 Click **OK**.

Step 12 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Data source_Task creation time*, and the subdirectory is used to save latest data source backup files.

----End

10.11.2.6 Backing Up DBService Data

Scenario

To ensure DBService service data security routinely or before a major operation on DBService (such as upgrade or migration), you need to back up DBService data. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up DBService data. Both automatic and manual backup tasks are supported.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.
- If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- The backup type, period, policy, and other specifications have been planned based on the service requirements and you have checked whether *Data storage path*/**LocalBackup/** has sufficient space on the active and standby management nodes.
- If you want to back up data to NAS, you have deployed the NAS server in advance.
- If you want to back up data to OBS, you have connected the current cluster to OBS and have the permission to access OBS.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task.

Periodic indicates that the backup task is executed by the system periodically. **Manual** indicates that the backup task is executed manually.

Table 10-81 Periodic backup parameters

Parameter	Description
Started	Indicates the time when the task is started for the first time.
Period	Indicates the task execution interval. The options include **Hours** and **Days**.

Parameter	Description
Backup Policy	• **Full backup at the first time and incremental backup subsequently** • **Full backup every time** • **Full backup once every n times** **NOTE** • Incremental backup is not supported when Manager data and component metadata are backed up. Only **Full backup every time** is supported. • If **Path Type** is set to **NFS** or **CIFS**, incremental backup cannot be used. When incremental backup is used for NFS or CIFS backup, the latest full backup data is updated each time the incremental backup is performed. Therefore, no new recovery point is generated.

Step 6 In **Configuration**, select **DBService**.

NOTE

If there are multiple DBService services, all DBService services are backed up by default. You can click **Assign Service** to specify the services to be backed up.

Step 7 Set **Path Type** of **DBService** to a backup directory type.

The following backup directory types are supported:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node and the standby management node automatically synchronizes the backup files.

  The default storage directory is *Data storage path*/**LocalBackup/**, for example, **/srv/BigData/LocalBackup**.

  If you select this option, you need to set the maximum number of replicas to specify the number of backup file sets that can be retained in the backup directory.
- **LocalHDFS**: indicates that the backup files are stored in the HDFS directory of the current cluster.

  If you select this option, set the following parameters:

  – **Target Path**: indicates the HDFS directory for storing the backup files. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.

  – **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

  – **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select this option, set the following parameters:

  – **Destination NameService Name**: indicates the NameService name of the standby cluster. You can set it to the NameService name (**haclusterX**,

haclusterX1, **haclusterX2**, **haclusterX3**, or **haclusterX4**) of the built-in remote cluster of the cluster, or the NameService name of a configured remote cluster.

- **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
- **Target NameNode IP Address**: indicates the IP address of the NameNode service plane in the standby cluster. It can be of an active or standby node.
- **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
- **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
- **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the source cluster.

- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol.

  If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
- **CIFS**: indicates that backup files are stored in the NAS using the CIFS protocol.

  If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)

  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select this option, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the server where the backup data is stored.
  - **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
  - **Username**: indicates the username for connecting to the server using the SFTP protocol.
  - **Password**: indicates the password for connecting to the server using the SFTP protocol.
  - **Server Shared Path**: indicates the backup path on the SFTP server.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
- **OBS**: indicates that backup files are stored in OBS.

  If you select this option, set the following parameters:
  - **Target Path**: indicates the OBS directory for storing backup data.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

Step 8 Click **OK**.

Step 9 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Task creation time*, and the subdirectory is used to save data source backup files.

The format of the backup file name is *Version_Data source_Task execution time*.**tar.gz**.

----End

10.11.2.7 Backing Up Flink Metadata

Scenario

To ensure Flink metadata security or before a major operation on Flink (such as upgrade or migration), you need to back up Flink metadata. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up Flink metadata. Both automatic and manual backup tasks are supported.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.
- The HDFS and Yarn services have been installed if data needs to be backed up to HDFS.
- The backup type, period, policy, and other specifications have been planned based on the service requirements and you have checked whether *Data storage path*/**LocalBackup/** has sufficient space on the active and standby management nodes.
- If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task. **Periodic** indicates that the backup task is periodically executed. **Manual** indicates that the backup task is manually executed.

To create a periodic backup task, set the following parameters:

- **Started**: indicates the time when the task is started for the first time.
- **Period**: indicates the task execution interval. The options include **Hours** and **Days**.
- **Backup Policy**: Only **Full backup every time** is supported.

Step 6 In **Configuration**, select **Flink** under **Metadata and other data**.

Step 7 Set **Path Type** of **Flink** to a backup directory type.

The following backup directory types are supported:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node and the standby management node automatically synchronizes the backup files.

  The default storage directory is *Data storage path*/**LocalBackup/**, for example, **/srv/BigData/LocalBackup**.

If you select this option, you need to set the maximum number of replicas to specify the number of backup file sets that can be retained in the backup directory.

- **LocalHDFS**: indicates that the backup files are stored in the HDFS directory of the current cluster.

  If you select this option, set the following parameters:

  - **Target Path**: indicates the HDFS directory for storing the backup files. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select this option, set the following parameters:

  - **Destination NameService Name**: indicates the NameService name of the standby cluster. You can set it to the NameService name (**haclusterX**, **haclusterX1**, **haclusterX2**, **haclusterX3**, or **haclusterX4**) of the built-in remote cluster of the cluster, or the NameService name of a configured remote cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Target NameNode IP Address**: indicates the IP address of the NameNode service plane in the standby cluster. It can be of an active or standby node.
  - **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the source cluster.

Step 8 Click **OK**.

Step 9 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Task creation time*, and the subdirectory is used to save data source backup files. The format of the backup file name is *Data source_Task execution time***.tar.gz**.

----End

10.11.2.8 Backing Up HBase Metadata

Scenario

To ensure HBase metadata security (including tableinfo files and HFiles) or before a major operation on HBase system tables (such as upgrade or migration), you need to back up HBase metadata to prevent HBase service unavailability caused by HBase system table directory or file damages. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up HBase metadata. Both automatic and manual backup tasks are supported.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.
- If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- The backup type, period, policy, and other specifications have been planned based on the service requirements and you have checked whether *Data storage path*/**LocalBackup/** has sufficient space on the active and standby management nodes.
- If you want to back up data to NAS, you have deployed the NAS server in advance.
- The **fs.defaultFS** parameter settings of HBase are the same as those of Yarn and HDFS.
- If HBase data is stored in the local HDFS, HBase metadata can be backed up to OBS. If HBase data is stored in OBS, data backup is not supported.
- If you want to back up data to OBS, you have connected the current cluster to OBS and have the permission to access OBS.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task.

Periodic indicates that the backup task is executed by the system periodically. **Manual** indicates that the backup task is executed manually.

Table 10-82 Periodic backup parameters

Parameter	Description
Started	Indicates the time when the task is started for the first time.
Period	Indicates the task execution interval. The options include **Hours** and **Days**.
Backup Policy	• **Full backup at the first time and incremental backup subsequently** • **Full backup every time** • **Full backup once every n times** **NOTE** • Incremental backup is not supported when Manager data and component metadata are backed up. Only **Full backup every time** is supported. • If **Path Type** is set to **NFS** or **CIFS**, incremental backup cannot be used. When incremental backup is used for NFS or CIFS backup, the latest full backup data is updated each time the incremental backup is performed. Therefore, no new recovery point is generated.

Step 6 In **Configuration**, select **HBase** under **Metadata and other data**.

NOTE

If there are multiple HBase services, all HBase services are backed up by default. You can click **Assign Service** to specify the services to be backed up.

Step 7 Set **Path Type** of **HBase** to a backup directory type.

The following backup directory types are supported:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node and the standby management node automatically synchronizes the backup files.

  The default storage directory is *Data storage path*/**LocalBackup/**, for example, **/srv/BigData/LocalBackup**.

  If you select this option, you need to set the maximum number of replicas to specify the number of backup file sets that can be retained in the backup directory.

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select this option, set the following parameters:

  – **Destination NameService Name**: indicates the NameService name of the standby cluster. You can set it to the NameService name (**haclusterX**, **haclusterX1**, **haclusterX2**, **haclusterX3**, or **haclusterX4**) of the built-in

remote cluster of the cluster, or the NameService name of a configured remote cluster.

- **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
- **Target NameNode IP Address**: indicates the IP address of the NameNode service plane in the standby cluster. It can be of an active or standby node.
- **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
- **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
- **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the source cluster.

- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol.

  If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
- **CIFS**: indicates that backup files are stored in the NAS using the CIFS protocol.

  If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the server where the backup data is stored.
  - **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
  - **Username**: indicates the username for connecting to the server using the SFTP protocol.
  - **Password**: indicates the password for connecting to the server using the SFTP protocol.
  - **Server Shared Path**: indicates the backup path on the SFTP server.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

- **OBS**: indicates that backup files are stored in OBS.

  If you select this option, set the following parameters:

  - **Target Path**: indicates the OBS directory for storing backup data.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

Step 8 Click **OK**.

Step 9 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Task creation time*, and the subdirectory is used to save data source backup files. The format of the backup file name is *Version_Data source_Task execution time*.**tar.gz**.

----End

10.11.2.9 Backing Up HBase Service Data

Scenario

To ensure HBase service data security routinely or before a major operation on HBase (such as upgrade or migration), you need to back up HBase service data. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up HBase service data. Both automatic and manual backup tasks are supported.

The following situations may occur during the HBase service data backup:

- When a user creates an HBase table, **KEEP_DELETED_CELLS** is set to **false** by default. When the user backs up this HBase table, deleted data will be backed up and junk data may exist after data restoration. This parameter can be set to **true** manually when an HBase table is created based on service requirements.
- When a user manually specifies the timestamp when writing data into an HBase table and the specified time is earlier than the last backup time of the HBase table, new data may not be backed up in incremental backup tasks.
- The HBase backup function cannot back up the access control lists (ACLs) for reading, writing, executing, creating, and managing HBase global or namespaces. After HBase data is restored, you need to reset the role permissions on FusionInsight Manager.
- If the backup data of the standby cluster is lost in an existing HBase backup task, the next incremental backup will fail, and you need to create an HBase backup task again. However, the next full backup task will be normal.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.
- If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- Backup policies, including the backup task type, period, backup object, backup directory, and Yarn queue required by the backup task are planned based on service requirements.
- The HDFS in the standby cluster has sufficient space. You are advised to save backup files in a custom directory.
- On the HDFS client, you have executed the **hdfs lsSnapshottableDir** command as user **hdfs** to check the list of directories for which HDFS snapshots have been created in the current cluster and ensured that the HDFS parent directory or subdirectory where data files to be backed up are stored does not have HDFS snapshots. Otherwise, the backup task cannot be created.
- If you want to back up data to NAS, you have deployed the NAS server in advance.
- The **fs.defaultFS** parameter settings of HBase are the same as those of Yarn and HDFS.
- If HBase data is stored in the local HDFS, HBase service data can be backed up to OBS. If HBase data is stored in OBS, data backup is not supported.
- If you want to back up data to OBS, you have connected the current cluster to OBS and have the permission to access OBS.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task.

Periodic indicates that the backup task is executed by the system periodically. **Manual** indicates that the backup task is executed manually.

Table 10-83 Periodic backup parameters

Parameter	Description
Started	Indicates the time when the task is started for the first time.
Period	Indicates the task execution interval. The options include **Hours** and **Days**.
Backup Policy	• **Full backup at the first time and incremental backup subsequently** • **Full backup every time** • **Full backup once every n times** **NOTE** • Incremental backup is not supported when Manager data and component metadata are backed up. Only **Full backup every time** is supported. • If **Path Type** is set to **NFS** or **CIFS**, incremental backup cannot be used. When incremental backup is used for NFS or CIFS backup, the latest full backup data is updated each time the incremental backup is performed. Therefore, no new recovery point is generated.

Step 6 In **Configuration**, choose **HBase** > **HBase** under **Service data**.

Step 7 Set **Path Type** of **HBase** to a backup directory type.

The following backup directory types are supported:

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select this option, set the following parameters:

  – **Destination NameService Name**: indicates the NameService name of the standby cluster. You can set it to the NameService name (**haclusterX**, **haclusterX1**, **haclusterX2**, **haclusterX3**, or **haclusterX4**) of the built-in remote cluster of the cluster, or the NameService name of a configured remote cluster.

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Target NameNode IP Address**: indicates the IP address of the NameNode service plane in the standby cluster. It can be of an active or standby node.
  - **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol.

  If you select this option, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
- **CIFS**: indicates that backup files are stored in the NAS using the CIFS protocol.

  If you select this option, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.

  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select this option, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the server where the backup data is stored.
  - **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
  - **Username**: indicates the username for connecting to the server using the SFTP protocol.
  - **Password**: indicates the password for connecting to the server using the SFTP protocol.
  - **Server Shared Path**: indicates the backup path on the SFTP server.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
- **OBS**: indicates that backup files are stored in OBS.

  If you select this option, you also need to configure the following parameters:
  - **Target Path**: indicates the OBS directory for storing backup data.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

- **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.
- **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
- **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.

Step 8 Set **Maximum Number of Recovery Points** to the number of snapshots that can be retained in the cluster.

Step 9 Set **Backup Content** to one or multiple HBase tables to be backed up.

You can select backup data using either of the following methods:

- Adding a backup data file
  a. Click **Add**.
  b. Select the table to be backed up under **File Directory**, and click **Add** to add the table to **Backup Content**.
  c. Click **OK**.
- Selecting using regular expressions
  a. Click **Query Regular Expression**.
  b. Enter the namespace where the HBase tables are located in the first text box as prompted. The namespace must be the same as the existing namespace, for example, **default**.
  c. Enter a regular expression in the second text box. Standard regular expressions are supported. For example, to get all tables in the namespace, enter **([\s\S]*?)**. To get tables whose names consist of letters and digits, for example, **tb1**, enter **tb\d***.
  d. Click **Refresh** to view the displayed tables in **Directory Name**.
  e. Click **Synchronize** to save the result.

  NOTE

  - When entering regular expressions, click + or − to add or delete an expression.
  - If the selected table or directory is incorrect, click **Clear Selected Node** to deselect it.

Step 10 Click **Verify** to check whether the backup task is configured correctly.

The possible causes of the verification failure are as follows:

- The target NameNode IP address is incorrect.
- The queue name is incorrect.
- The parent directory or subdirectory of the HDFS directory where HBase table data files to be backed up are stored has HDFS snapshots.
- The directory or table to be backed up does not exist.

Step 11 Click **OK**.

Step 12 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *xxx/Backup task name_Data source_Task creation time*, and the subdirectory is used to save latest data source backup files. All the backup file sets are stored in the related snapshot directories.

----End

10.11.2.10 Backing Up Elasticsearch Service Data

Scenario

To ensure Elasticsearch service data security routinely or before a major operation on Elasticsearch (such as upgrade or migration), you need to back up Elasticsearch service data. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up Elasticsearch service data. Both automatic and manual backup tasks are supported.

NOTICE

- During the snapshot creation, the search and query functions are not affected. After the snapshot creation process starts, new data is not recorded in the snapshot. Only one snapshot can be created at a time.
- When a backup task is created, only the indexes that have been enabled in the cluster are displayed as backup objects. The disabled indexes are not displayed on the GUI. This way, the disabled indexes are not backed up.
- If some indexes selected for a backup task are disabled before the backup task starts, the disabled indexes will not be backed up. Only enabled indexes are backed up. If all indexes are disabled, the backup task fails to be executed.
- The Elasticsearch service data backup needs to invoke the snapshot interface through the EsNode1 instance. Therefore, ensure that all EsNode1 instances in the cluster are in good health status and can receive requests normally. To ensure successful backup, do not perform operations such as adding, deleting, stopping, or restarting Elasticsearch instances, stopping or restarting the Elasticsearch service, or stopping or restarting the cluster.
- If a large amount of data needs to be backed up in the cluster, back up data at the index level in batches. Otherwise, the backup takes a long time.
- To prevent a large amount of data from being fully backed up each time, create a periodic backup task when creating an index. In this case, data is fully backed up in the first backup task, and incremental backup is performed in subsequent periodic backup tasks.
- If a backup task fails, log in to the backup directory of the target (**RemoteHDFS** and **NFS**), which is the value of **Target Path** for a backup to remote HDFS or the value of **Server Shared Path** for a backup to the NFS. Delete the subdirectory (*Backup task name_Data source_Task creation time*) corresponding to the backup task name to delete data that fails to be backed up.
- Before the backup, check whether the index to be backed up is in the green state and no shard is lost. Otherwise, the backup fails.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.
- The HDFS and Yarn services have been installed if data needs to be backed up to HDFS. For the Elasticsearch cluster in normal mode, service data cannot be backed up to HDFS in a cluster in security mode.
- The HDFS service has been installed if data needs to be backed up to the NAS.
- If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.

- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- The HDFS and NAS client in the standby cluster have sufficient space. You are advised to save backup files in a custom directory.
- When backing up the Elasticsearch service data to the NAS (NFS), you have deployed the NAS server and performed the following operations:

  After the NAS is started and a shared path is created, create a local repository path and mount it to the shared path of the NAS.

  a. Create a shared path of the NAS and change its owner and permission. For example, the shared path is **/var/nfs**.

     - Run **mkdir /var/nfs** to create a path.
     - Run **chown 65534:65534 /var/nfs** to change the owner.
     - Run **chmod 777 /var/nfs** to change the permission.

  b. On each server, run the following command to mount the local repository path to the shared path of the NAS:

     mount *ip*:**/var/nfs /***Data storage path*/**elasticsearch/nas**

     In the command, **ip** indicates the IP address of the NAS server. For example:

     mount *ip*:**/var/nfs /srv/BigData/elasticsearch/nas**

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task. **Periodic** indicates that the backup task is periodically executed. **Manual** indicates that the backup task is manually executed.

To create a periodic backup task, set the following parameters:

- **Started**: indicates the time when the task is started for the first time.
- **Period**: indicates the task execution interval. The options include **Hours** and **Days**.
- **Backup Policy**: indicates the volume of data to be backed up in each task execution. Only **Full backup at the first time and incremental backup subsequently** is supported.

Step 6 In **Configuration**, choose **Elasticsearch** > **Elasticsearch** under **Service data**.

Step 7 Set **Path Type** of **Elasticsearch** to a backup directory type. Elasticsearch data cannot be backed up to a directory encrypted using RangerKMS.

The following backup directory types are supported:

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Destination Hadoop PRC Mode**: indicates the value of **hadoop.rpc.protection** in the HDFS basic configuration of the destination cluster.
  - **Destination Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the destination cluster.
  - **Destination Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the destination cluster.
  - **Destination NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the destination cluster.
  - **Target Path**: indicates the HDFS directory for storing destination cluster backup data. The path cannot be an HDFS hidden directory, such as snapshot or recycle bin directory, or a default system directory.

- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol.

  If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Backup Speed of a Single Instance (MB/s)**: indicates the speed of backing up data for a single instance. The default value is **50 MB/s**. Change the backup speed based on the actual volume of backup data.
  - **Restoration Speed of a Single Instance (MB/s)**: indicates the speed of restoring data for a single instance. The default value is **50 MB/s**. Change the restoration speed based on the actual volume of backup data.
  - **Server Shared Path**: indicates the shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)

Step 8 Set **Maximum Number of Recovery Points** to any value from **1** to **1000** because this parameter is not used by Elasticsearch.

Step 9 Set **Backup Content** to one or more indexes to be backed up.

You can select backup data using either of the following methods:

- Adding a backup data file

  a. Click **Add**.

  b. Select the table to be backed up under **File Directory**, and click **Add** to add the table to **Backup Content**.

  c. Click **OK**.

- Selecting using regular expressions
  a. Click **Query Regular Expression**.
  b. Enter a regular expression in the second text box. Standard regular expressions are supported. For example, to get indexes containing **es**, enter **.*es.***. To get indexes starting with **es**, enter **es.***. To get indexes ending with **es**, enter **.*es**.
  c. Click **Refresh** to view the displayed tables in **Directory Name**.
  d. Click **Synchronize** to save the result.

  NOTE

  - When entering regular expressions, click + or − to add or delete an expression.
  - If the selected table or directory is incorrect, click **Clear Selected Node** to deselect it.

Step 10 Click **Verify** to check whether the backup task is configured correctly.

The possible causes of the verification failure are as follows:

- The destination active or standby NameNode IP address or port number is incorrect.
- The name of the index to be backed up does not exist in the Elasticsearch cluster.

Step 11 Click **OK**.

Step 12 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Data source_Task creation time*, and the subdirectory is used to save latest data source backup files. All the backup file sets are stored in the related snapshot directories.

----End

10.11.2.11 Backing Up MOTService Service Data

Scenario

To ensure MOTService service data security routinely or before a major operation on MOTService (such as upgrade or migration), you need to back up MOTService service data. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up MOTService service data. Both automatic and manual backup tasks are supported.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby

cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.

- If the active cluster is deployed in security mode (with Kerberos authentication enabled) and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust must be configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode (with Kerberos authentication disabled), mutual trust is not required.
- The time on the active and standby clusters must be the same, and the NTP service on the active and standby clusters uses the same time source.
- You have planned the backup type, period, object, and directory based on service requirements.
- The HDFS in the standby cluster has sufficient space. You are advised to save backup files in a custom directory.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task.

Periodic indicates that the backup task is executed by the system periodically. **Manual** indicates that the backup task is executed manually.

Table 10-84 Periodic backup parameters

Parameter	Description
Started	The time when the task is started for the first time.
Period	The task execution interval. Value options include **Hours** and **Days**.
Backup Policy	Only **Full backup every time** is supported. • **Full backup at the first time and incremental backup subsequently** • **Full backup every time** • **Full backup once every n times**

Step 6 In **Configuration**, choose **MOTService** > **MOTService** under **Service data**.

Step 7 Set **Path Type** of **MOTService** to a backup directory type.

Currently, the backup directory supports only the **RemoteHDFS** type. **RemoteHDFS** indicates the HDFS directory for storing backup files in the standby cluster.

- **Destination NameService Name**: indicates the NameService name of the standby cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster.
- **IP Mode**: indicates the mode of the target IP address. The system automatically selects an IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
- **Destination Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster.
- **Destination Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster.
- **Destination NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the destination cluster.
- **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.

Step 8 Click **OK**.

Step 9 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Data source_Task creation time*, and the subdirectory is used to save latest data source backup files.

----End

10.11.2.12 Backing Up NameNode Data

Scenario

To ensure NameNode service data security routinely or before a major operation on NameNode (such as upgrade or migration), you need to back up NameNode data. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up NameNode data. Both automatic and manual backup tasks are supported.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.
- If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual**

Trust Between Clusters. If the active cluster is deployed in normal mode, no mutual trust is required.

- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- The backup type, period, policy, and other specifications have been planned based on the service requirements and you have checked whether *Data storage path*/**LocalBackup/** has sufficient space on the active and standby management nodes.
- If you want to back up data to NAS, you have deployed the NAS server in advance.
- If you want to back up data to OBS, you have connected the current cluster to OBS and have the permission to access OBS.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task.

Periodic indicates that the backup task is executed by the system periodically. **Manual** indicates that the backup task is executed manually.

Table 10-85 Periodic backup parameters

Parameter	Description
Started	Indicates the time when the task is started for the first time.
Period	Indicates the task execution interval. The options include **Hours** and **Days**.
Backup Policy	Only **Full backup every time** is supported. **NOTE** • Incremental backup is not supported when Manager data and component metadata are backed up. Only **Full backup every time** is supported. • If **Path Type** is set to **NFS** or **CIFS**, incremental backup cannot be used. When incremental backup is used for NFS or CIFS backup, the latest full backup data is updated each time the incremental backup is performed. Therefore, no new recovery point is generated.

Step 6 In **Configuration**, select **NameNode**.

Step 7 Set **Path Type** of **NameNode** to a backup directory type.

The following backup directory types are supported:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node and the standby management node automatically synchronizes the backup files. By default, the backup files are stored in *Data storage path*/**LocalBackup/**.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster. If you select this option, set the following parameters:
  - **Destination NameService Name**: indicates the NameService name of the standby cluster. You can set it to the NameService name (**haclusterX**, **haclusterX1**, **haclusterX2**, **haclusterX3**, or **haclusterX4**) of the built-in remote cluster of the cluster, or the NameService name of a configured remote cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Target NameNode IP Address**: indicates the service plane IP address of the NameNode in the standby cluster.
  - **Target Path**: indicates the path for storing backup files.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.
- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol. If you select this option, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
- **CIFS**: indicates that backup files are stored in the NAS using the CIFS protocol. If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select this option, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the server where the backup data is stored.
  - **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
  - **Username**: indicates the username for connecting to the server using the SFTP protocol.
  - **Password**: indicates the password for connecting to the server using the SFTP protocol.
  - **Server Shared Path**: indicates the backup path on the SFTP server.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
- **OBS**: indicates that backup files are stored in OBS.

  If you select this option, set the following parameters:
  - **Target Path**: indicates the OBS directory for storing backup data.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.

Step 8 Click **OK**.

Step 9 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Task creation time*, and the subdirectory is used to save data source backup files.

The format of the backup file name is *Version_Data source_Task execution time*.**tar.gz**.

----End

10.11.2.13 Backing Up HDFS Service Data

Scenario

To ensure HDFS service data security routinely or before a major operation on HDFS (such as upgrade or migration), you need to back up HDFS service data. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up HDFS service data. Both automatic and manual backup tasks are supported.

NOTE

Encrypted directories cannot be backed up or restored.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.
- If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- Backup policies, including the backup task type, period, backup object, backup directory, and Yarn queue required by the backup task are planned based on service requirements.
- The HDFS in the standby cluster has sufficient space. You are advised to save backup files in a custom directory.
- On the HDFS client, you have executed the **hdfs lsSnapshottableDir** command as user **hdfs** to check the list of directories for which HDFS snapshots have been created in the current cluster and ensured that the HDFS

parent directory or subdirectory where data files to be backed up are stored does not have HDFS snapshots. Otherwise, the backup task cannot be created.

- If you want to back up data to NAS, you have deployed the NAS server in advance.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task.

Periodic indicates that the backup task is executed by the system periodically. **Manual** indicates that the backup task is executed manually.

Table 10-86 Periodic backup parameters

Parameter	Description
Started	Indicates the time when the task is started for the first time.
Period	Indicates the task execution interval. The options include **Hours** and **Days**.
Backup Policy	• **Full backup at the first time and incremental backup subsequently** • **Full backup every time** • **Full backup once every n times** **NOTE** • Incremental backup is not supported when Manager data and component metadata are backed up. Only **Full backup every time** is supported. • If **Path Type** is set to **NFS** or **CIFS**, incremental backup cannot be used. When incremental backup is used for NFS or CIFS backup, the latest full backup data is updated each time the incremental backup is performed. Therefore, no new recovery point is generated.

Step 6 In **Configuration**, select **HDFS**.

Step 7 Set **Path Type** of **HDFS** to a backup directory type.

The following backup directory types are supported:

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select this option, set the following parameters:

  - **Destination NameService Name**: indicates the NameService name of the standby cluster. You can set it to the NameService name (**haclusterX**, **haclusterX1**, **haclusterX2**, **haclusterX3**, or **haclusterX4**) of the built-in remote cluster of the cluster, or the NameService name of a configured remote cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Target NameNode IP Address**: indicates the IP address of the NameNode service plane in the standby cluster. It can be of an active or standby node.
  - **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
  - **NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol.

  If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
  - **NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.

- **CIFS**: indicates that backup files are stored in the NAS using the CIFS protocol. If you select this option, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
  - **NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select this option, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the server where the backup data is stored.
  - **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
  - **Username**: indicates the username for connecting to the server using the SFTP protocol.
  - **Password**: indicates the password for connecting to the server using the SFTP protocol.
  - **Server Shared Path**: indicates the backup path on the SFTP server.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.

  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
  - **NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.

Step 8 Set **Maximum Number of Recovery Points** to the number of snapshots that can be retained in the cluster.

Step 9 Set **Backup Content** to one or multiple HDFS directories to be backed up based on service requirements.

You can select backup data using either of the following methods:

- Adding a backup data file
  a. Click **Add**.
  b. Select the table to be backed up under **File Directory**, and click **Add** to add the table to **Backup Content**.
  c. Click **OK**.
- Selecting using regular expressions
  a. Click **Query Regular Expression**.
  b. Enter the parent directory full path of the directory in the first text box as prompted. The directory must be the same as the existing directory, for example, **/tmp**.
  c. Enter a regular expression in the second text box. Standard regular expressions are supported. For example, to get all files or subdirectories in the parent directory, enter **([\s\S]*?)**. To get files whose names consist of letters and digits, for example, **file*1***, enter **file\d***.
  d. Click **Refresh** to view the displayed directories in **Directory Name**.
  e. Click **Synchronize** to save the result.

  NOTE

  - When entering regular expressions, click + or — to add or delete an expression.
  - If the selected table or directory is incorrect, click **Clear Selected Node** to deselect it.
  - The backup directory cannot contain files that have been written for a long time. Otherwise, the backup task will fail. Therefore, you are not advised to perform operations on the top-level directory, such as **/user**, **/tmp**, and **/mr-history**.

Step 10 Click **Verify** to check whether the backup task is configured correctly.

The possible causes of the verification failure are as follows:

- The target NameNode IP address is incorrect.
- The queue name is incorrect.
- The parent directory or subdirectory of the HDFS directory where data files to be backed up are stored has HDFS snapshots.
- The directory or table to be backed up does not exist.
- The name of the NameService is incorrect.

Step 11 Click **OK**.

Step 12 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Data source_Task creation time*, and the subdirectory is used to save latest data source backup files. All the backup file sets are stored in the related snapshot directories.

----End

10.11.2.14 Backing Up Hive Service Data

Scenario

To ensure Hive service data security routinely or before a major operation on Hive (such as upgrade or migration), you need to back up Hive service data. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up Hive service data. Both automatic and manual backup tasks are supported.

- Hive backup and restoration cannot identify the service and structure relationships of objects such as Hive tables, indexes, and views. When executing backup and restoration tasks, you need to manage unified restoration points based on service scenarios to ensure proper service running.
- Hive backup and restoration do not support Hive on RDB data tables. You need to back up and restore original data tables in external databases independently.
- If the backup data of the standby cluster is lost in an existing Hive backup task that contains Hive on HBase tables, the next incremental backup will fail, and you need to create a Hive backup task again. However, the next full backup task will be normal.
- After the backup function of FusionInsight Manager is used to back up the HDFS directories at the Hive table level, the Hive tables cannot be deleted and recreated.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.
- If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.

- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- Backup policies, including the backup task type, period, backup object, backup directory, and Yarn queue required by the backup task are planned based on service requirements.
- The HDFS in the standby cluster has sufficient space. You are advised to save backup files in a custom directory.
- On the HDFS client, you have executed the **hdfs lsSnapshottableDir** command as user **hdfs** to check the list of directories for which HDFS snapshots have been created in the current cluster and ensured that the HDFS parent directory or subdirectory where data files to be backed up are stored does not have HDFS snapshots. Otherwise, the backup task cannot be created.
- If you want to back up data to NAS, you have deployed the NAS server in advance.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task.

Periodic indicates that the backup task is executed by the system periodically. **Manual** indicates that the backup task is executed manually.

Table 10-87 Periodic backup parameters

Parameter	Description
Started	Indicates the time when the task is started for the first time.
Period	Indicates the task execution interval. The options include **Hours** and **Days**.
Backup Policy	• **Full backup at the first time and incremental backup subsequently** • **Full backup every time** • **Full backup once every n times** **NOTE** • Incremental backup is not supported when Manager data and component metadata are backed up. Only **Full backup every time** is supported. • If **Path Type** is set to **NFS** or **CIFS**, incremental backup cannot be used. When incremental backup is used for NFS or CIFS backup, the latest full backup data is updated each time the incremental backup is performed. Therefore, no new recovery point is generated.

Step 6 In **Configuration**, choose **Hive** > **Hive**.

Step 7 Set **Path Type** of **Hive** to a backup directory type.

The following backup directory types are supported:

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster. If you select this option, set the following parameters:
  - **Destination NameService Name**: indicates the NameService name of the standby cluster. You can set it to the NameService name (**haclusterX**, **haclusterX1**, **haclusterX2**, **haclusterX3**, or **haclusterX4**) of the built-in remote cluster of the cluster, or the NameService name of a configured remote cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Target NameNode IP Address**: indicates the IP address of the NameNode service plane in the standby cluster. It can be of an active or standby node.
  - **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
  - **NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol. If you select this option, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.

  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
  - **NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
- **CIFS**: indicates that backup files are stored in the NAS using the CIFS protocol. If you select this option, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
  - **NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select this option, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the server where the backup data is stored.
  - **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
  - **Username**: indicates the username for connecting to the server using the SFTP protocol.
  - **Password**: indicates the password for connecting to the server using the SFTP protocol.

  - **Server Shared Path**: indicates the backup path on the SFTP server.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
  - **NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.

Step 8 Set **Maximum Number of Recovery Points** to the number of snapshots that can be retained in the cluster.

Step 9 Set **Backup Content** to one or multiple Hive tables to be backed up.

You can select backup data using either of the following methods:

- Adding a backup data file
  a. Click **Add**.
  b. Select the table to be backed up under **File Directory**, and click **Add** to add the table to **Backup Content**.
  c. Click **OK**.
- Selecting using regular expressions
  a. Click **Query Regular Expression**.
  b. Enter the database where the Hive tables are located in the first text box as prompted. The database must be the same as the existing database, for example, **default**.
  c. Enter a regular expression in the second text box. Standard regular expressions are supported. For example, to get all tables in the database, enter **([\s\S]*?)**. To get tables whose names consist of letters and digits, for example, **tb1**, enter **tb\d***.
  d. Click **Refresh** to view the displayed tables in **Directory Name**.
  e. Click **Synchronize** to save the result.

  NOTE

  - When entering regular expressions, click + or — to add or delete an expression.
  - If the selected table or directory is incorrect, click **Clear Selected Node** to deselect it.

Step 10 Click **Verify** to check whether the backup task is configured correctly.

The possible causes of the verification failure are as follows:

- The target NameNode IP address is incorrect.
- The queue name is incorrect.
- The parent directory or subdirectory of the HDFS directory where data files to be backed up are stored has HDFS snapshots.

- The directory or table to be backed up does not exist.
- The name of the NameService is incorrect.

Step 11 Click **OK**.

Step 12 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Data source_Task creation time*, and the subdirectory is used to save latest data source backup files. All the backup file sets are stored in the related snapshot directories.

----End

10.11.2.15 Backing Up IoTDB Metadata

Scenario

To ensure IoTDB metadata security and prevent the IoTDB service from being unavailable due to IoTDB metadata file damages, you need to back up IoTDB metadata. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up IoTDB metadata. Both automatic and manual backup tasks are supported.

Prerequisites

- The backup type, period, policy, and other specifications have been planned based on the service requirements and you have checked whether *Data storage path*/**LocalBackup/** has sufficient space on the active and standby management nodes.
- If you want to back up data to NAS, you have deployed the NAS server in advance.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- Backup policies, including the backup task type, period, backup object, backup directory, and Yarn queue required by the backup task are planned based on service requirements.
- The HDFS in the standby cluster has sufficient space. You are advised to save backup files in a custom directory.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task.

Periodic indicates that the backup task is executed by the system periodically. **Manual** indicates that the backup task is executed manually.

Table 10-88 Periodic backup parameters

Parameter	Description
Started	Indicates the time when the task is started for the first time.
Period	Indicates the task execution interval. The options include **Hours** and **Days**.
Backup Policy	Indicates a periodic backup policy. • **Full backup at the first time and incremental backup subsequently** • **Full backup every time** • **Full backup once every n times** **NOTE** Incremental backup is not supported when component metadata is backed up. Only **Full backup every time** is supported.

Step 6 In **Configuration**, select **IoTDB** under **Metadata and other data**.

NOTE

If there are multiple IoTDB services, all IoTDB services are backed up by default. You can click **Assign Service** to specify the services to be backed up.

Step 7 Set **Path Type** of **IoTDB** to a backup directory type.

The following backup directory types are supported:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node and the standby management node automatically synchronizes the backup files. By default, the backup files are stored in *Data storage path*/**LocalBackup/**.

  If you select this option, you need to set the maximum number of replicas to specify the number of backup file sets that can be retained in the backup directory.

- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol.

  If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)

  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select this option, set the following parameters:

  - **Destination NameService Name**: indicates the NameService name of the standby cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Destination Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster.
  - **Destination Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster.
  - **Destination NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the standby cluster.
  - **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

- **CIFS**: indicates that backup files are stored in the NAS using the CIFS protocol.

  If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select this option, set the following parameters:

- **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
- **Server IP Address**: indicates the IP address of the server where the backup data is stored.
- **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
- **Username**: indicates the username for connecting to the server using the SFTP protocol.
- **Password**: indicates the password for connecting to the server using the SFTP protocol.
- **Server Shared Path**: indicates the backup path on the SFTP server.
- **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

Step 8 Click **OK**.

Step 9 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Task creation time*, and the subdirectory is used to save data source backup files.

The format of the backup file name is *Version_Data source_Task execution time*.**tar.gz**.

----End

10.11.2.16 Backing Up IoTDB Service Data

Scenario

To ensure IoTDB service data security routinely or before a major operation on IoTDB (such as upgrade or migration), you need to back up IoTDB service data. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up IoTDB service data. Both automatic and manual backup tasks are supported.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster. Currently, IoTDB data can be backed up only to HDFS.
- For the IoTDB cluster in normal mode, service data cannot be backed up to HDFS in a cluster in security mode.

- If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- The HDFS in the standby cluster has sufficient space. You are advised to save backup files in a custom directory.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task.

Periodic indicates that the backup task is executed by the system periodically. **Manual** indicates that the backup task is executed manually.

Table 10-89 Periodic backup parameters

Parameter	Description
Started	Indicates the time when the task is started for the first time.
Period	Indicates the task execution interval. The options include **Hours** and **Days**.
Backup Policy	Indicates a periodic backup policy. • **Full backup at the first time and incremental backup subsequently** • **Full backup every time** • **Full backup once every n times** **NOTE** Incremental backup is not supported when component service data is backed up. Only **Full backup every time** is supported.

Step 6 In **Configuration**, choose **IoTDB** > **IoTDB** under **Service data**.

Step 7 Set **Path Type** of **IoTDB** to a backup directory type.

The following backup directory types are supported:

RemoteHDFS: indicates that the backup files are stored in the HDFS directory of the standby cluster.

If you select this option, set the following parameters:

- **Destination NameService Name**: indicates the NameService name of the standby cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster.
- **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
- **Destination Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster.
- **Destination Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster.
- **Destination NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the standby cluster.
- **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.

Step 8 Set **Backup Content** to one or multiple service data records to be backed up.

You can select backup data using either of the following methods:

- Adding a backup data file
  a. Click **Add**.
  b. Select the table to be backed up under **File Directory**, and click **Add** to add the table to **Backup Content**.
  c. Click **OK**.
- Selecting using regular expressions
  a. Click **Query Regular Expression**.
  b. Enter the parent directory full path of the directory in the first text box as prompted. The directory must be the same as the existing directory, for example, **/root**.
  c. Enter a regular expression in the second text box. Standard regular expressions are supported. For example, to get all files or subdirectories in the parent directory, enter **([\s\S]*?)**. To get files whose names consist of letters and digits, for example, **file*1***, enter **file\d***.
  d. Enter a regular expression in the second text box. Standard regular expressions are supported. For example, to get objects containing **test**, enter **.*test.***. To get objects starting with **test**, enter **test.***. To get objects ending with **test**, enter **.*test**.
  e. Click **Refresh** to view the displayed directories in **Directory Name**.
  f. Click **Synchronize** to save the result.

NOTE

- When entering regular expressions, click + or − to add or delete an expression.
- If the selected table or directory is incorrect, click **Clear Selected Node** to deselect it.
- The backup directory cannot contain files that have been written for a long time. Otherwise, the backup task will fail. Therefore, you are not advised to perform operations on the top-level directory, such as **/user**, **/tmp**, and **/mr-history**.

Step 9 Click **Verify** to check whether the backup task is configured correctly.

The possible causes of the verification failure are as follows:

- The target NameNode IP address is incorrect.
- The data to be backed up does not exist.

Step 10 Click **OK**.

Step 11 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Data source_Task creation time*, and the subdirectory is used to save latest data source backup files. All the backup file sets are stored in the related snapshot directories.

----End

10.11.2.17 Backing Up Kafka Metadata

Scenario

To ensure Kafka metadata security or before a major operation on ZooKeeper (such as upgrade or migration), you need to back up Kafka metadata. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up Kafka metadata. Both automatic and manual backup tasks are supported.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.
- If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.

- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- The backup type, period, policy, and other specifications have been planned based on the service requirements and you have checked whether *Data storage path*/**LocalBackup/** has sufficient space on the active and standby management nodes.
- If you want to back up data to NAS, you have deployed the NAS server in advance.
- If you want to back up data to OBS, you have connected the current cluster to OBS and have the permission to access OBS.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task.

Periodic indicates that the backup task is executed by the system periodically. **Manual** indicates that the backup task is executed manually.

Table 10-90 Periodic backup parameters

Parameter	Description
Started	Indicates the time when the task is started for the first time.
Period	Indicates the task execution interval. The options include **Hours** and **Days**.
Backup Policy	• **Full backup at the first time and incremental backup subsequently** • **Full backup every time** • **Full backup once every n times** **NOTE** • Incremental backup is not supported when Manager data and component metadata are backed up. Only **Full backup every time** is supported. • If **Path Type** is set to **NFS** or **CIFS**, incremental backup cannot be used. When incremental backup is used for NFS or CIFS backup, the latest full backup data is updated each time the incremental backup is performed. Therefore, no new recovery point is generated.

Step 6 In **Configuration**, select **Kafka**.

NOTE

If there are multiple Kafka services, all Kafka services are backed up by default. You can click **Assign Service** to specify the services to be backed up.

Step 7 Set **Path Type** of **Kafka** to a backup directory type.

The following backup directory types are supported:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node and the standby management node automatically synchronizes the backup files. By default, the backup files are stored in *Data storage path*/**LocalBackup/**.

  If you select this option, you need to set the maximum number of replicas to specify the number of backup file sets that can be retained in the backup directory.

- **LocalHDFS**: indicates that the backup files are stored in the HDFS directory of the current cluster.

  If you select this option, set the following parameters:

  - **Target Path**: indicates the HDFS directory for storing the backup files. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select this option, set the following parameters:

  - **Destination NameService Name**: indicates the NameService name of the standby cluster. You can set it to the NameService name (**haclusterX**, **haclusterX1**, **haclusterX2**, **haclusterX3**, or **haclusterX4**) of the built-in remote cluster of the cluster, or the NameService name of a configured remote cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Target NameNode IP Address**: indicates the IP address of the NameNode service plane in the standby cluster. It can be of an active or standby node.
  - **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.

- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol.

  If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

- **CIFS**: indicates that backup files are stored in the NAS using the CIFS protocol.

  If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

- **OBS**: indicates that backup files are stored in OBS.

  If you select this option, set the following parameters:

  - **Target Path**: indicates the OBS directory for storing backup data.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

Step 8 Click **OK**.

Step 9 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Task creation time*, and the subdirectory is used to save data source backup files. The format of the backup file name is *Version_Data source_Task execution time*.**tar.gz**.

----End

10.11.2.18 Backing Up Redis Data

Scenario

To ensure Redis data security routinely or before a major operation on a Redis cluster (such as upgrade or migration), you need to back up Redis cluster data. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up Redis cluster data. To prevent the Redis service from being severely affected, manually back up data.

Prerequisites

- You have checked that HDFS services have been deployed in the current cluster.
- The HDFS in the standby cluster has sufficient space. You are advised to save backup files in a custom directory.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task. **Periodic** indicates that the backup task is periodically executed. **Manual** indicates that the backup task is manually executed.

To create a periodic backup task, set the following parameters:

- **Started**: indicates the time when the task is started for the first time.
- **Period**: indicates the task execution interval. The options include **Hours** and **Days**.
- **Backup Policy**: Only **Full backup every time** is supported.

  NOTE

  - AOF persistency is performed on full data when a backup task is executed on Redis. If the service data volume is large, the performance is greatly affected. You are advised not to periodically back up Redis data.
  - Manually back up Redis data during off-peak hours.

Step 6 In **Configuration**, select **Redis**.

Step 7 Set **Path Type** of **Redis** to a backup directory type.

The following backup directory types are supported:

- **LocalHDFS**: indicates that the backup files are stored in the HDFS directory of the current cluster.

If you select this option, set the following parameters:

- **Target Path**: indicates the HDFS directory for storing the backup files. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.

  NOTE

  - The target path of Redis data backup cannot be set to the SM4 encrypted partition of HDFS.
  - The target path can be a path that does not exist in HDFS. A path will be automatically created during the backup.

- **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
- **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.

Step 8 Click **OK**.

Step 9 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for the backup task in the backup directory. The format of the subdirectory name is *Backup task name_Data source_Task creation time*.

----End

10.11.2.19 Backing Up RTDService Metadata

Scenario

To ensure RTDService metadata security or before a major operation on RTDService (such as upgrade or migration), you need to back up RTDService metadata. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up RTDService metadata. Both automatic and manual backup tasks are supported.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster.
- The backup type, period, policy, and other specifications have been planned based on the service requirements and you have checked whether *Data storage path***/LocalBackup/** has sufficient space on the active and standby management nodes.
- If the active cluster is deployed in security mode (with Kerberos authentication enabled) and the active and standby clusters are not managed

by the same FusionInsight Manager, mutual trust must be configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode (with Kerberos authentication disabled), mutual trust is not required.

- The time on the active and standby clusters must be the same, and the NTP service on the active and standby clusters uses the same time source.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task. **Periodic** indicates that the backup task is periodically executed. **Manual** indicates that the backup task is manually executed.

To create a periodic backup task, set the following parameters:

Table 10-91 Periodic backup parameters

Parameter	Description
Started	The time when the task is started for the first time.
Period	The task execution interval. Value options include **Hours** and **Days**.
Backup Policy	• **Full backup at the first time and incremental backup subsequently** • **Full backup every time** • **Full backup once every n times**

Step 6 In **Configuration**, select **RTDService** under **Metadata and other data**.

Step 7 Set **Path Type** of **RTDService** to a backup directory type.

The following backup directory types are supported:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node and the standby management node automatically synchronizes the backup files.

  The default storage directory is *Data storage path*/**LocalBackup/**, for example, **/srv/BigData/LocalBackup**.

  If you select this option, you need to set the maximum number of replicas to specify the number of backup file sets that can be retained in the backup directory.
- **LocalHDFS**: indicates that the backup files are stored in the HDFS directory of the current cluster.

If you select this option, you also need to configure the following parameters:

- **Target Path**: indicates the HDFS directory for storing the backup files. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
- **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
- **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.

- **RemoteHDFS**: indicates that backup files are stored in HDFS of the standby cluster.

  You also need to set the following parameters:

  - **Destination NameService Name**: indicates the NameService name of the standby cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects an IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Destination Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster.
  - **Destination Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster.
  - **Destination NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the destination cluster.
  - **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.

Step 8 Click **OK**.

Step 9 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Task creation time*, and the subdirectory is used to save data source backup files. The format of the backup file name is *Data source_Task execution time*.**tar.gz**.

----End

10.11.2.20 Backing Up Solr Metadata

Scenario

Solr metadata is stored in ZooKeeper. To ensure Solr metadata security or before a major operation on ZooKeeper (such as upgrade or migration), you need to back up Solr metadata. The backup data can be used to recover the system if an

exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up Solr metadata. Both automatic and manual backup tasks are supported.

Prerequisites

- The backup type, period, policy, and other specifications have been planned based on the service requirements and you have checked whether *Data storage path*/**LocalBackup/** has sufficient space on the active and standby management nodes.
- If you want to back up data to NAS, you have deployed the NAS server in advance.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task.

Periodic indicates that the backup task is executed by the system periodically. **Manual** indicates that the backup task is executed manually.

Table 10-92 Periodic backup parameters

Parameter	Description
Started	Indicates the time when the task is started for the first time.
Period	Indicates the task execution interval. The options include **Hours** and **Days**.
Backup Policy	Indicates a periodic backup policy. • **Full backup at the first time and incremental backup subsequently** • **Full backup every time** • **Full backup once every n times** **NOTE** Incremental backup is not supported when component metadata is backed up. Only **Full backup every time** is supported.

Step 6 In **Configuration**, select **Solr** under **Metadata and other data**.

NOTE

If there are multiple Solr services, all Solr services are backed up by default. You can click **Assign Service** to specify the services to be backed up.

Step 7 Set **Path Type** of **Solr** to a backup directory type.

The following backup directory types are supported:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node and the standby management node automatically synchronizes the backup files. By default, the backup files are stored in *Data storage path*/**LocalBackup/**.

  If you select this option, you need to set the maximum number of replicas to specify the number of backup file sets that can be retained in the backup directory.

- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol.

  If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select this option, set the following parameters:

  - **Destination NameService Name**: indicates the NameService name of the standby cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Destination Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster.
  - **Destination Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster.
  - **Destination NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the standby cluster.
  - **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

- **CIFS**: indicates that backup files are stored in the NAS using the CIFS protocol.

  If you select this option, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Server Shared Path**: indicates the configured shared directory of the NAS server. (The shared path of the server cannot be set to the root directory, and the user group and owner group of the shared path must be **nobody:nobody**.)
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.
- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select this option, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the server where the backup data is stored.
  - **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
  - **Username**: indicates the username for connecting to the server using the SFTP protocol.
  - **Password**: indicates the password for connecting to the server using the SFTP protocol.
  - **Server Shared Path**: indicates the backup path on the SFTP server.
  - **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

Step 8 Click **OK**.

Step 9 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Task creation time*, and the subdirectory is used to save data source backup files.

The format of the backup file name is *Version_Data source_Task execution time*.**tar.gz**.

----End

10.11.2.21 Backing Up Solr Service Data

Scenario

To ensure Solr service data security routinely or before a major operation on Solr (such as upgrade or migration), you need to back up Solr service data. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

You can create a backup task on FusionInsight Manager to back up Solr service data. Both automatic and manual backup tasks are supported.

NOTICE

- During snapshot creation, the search and query functions are not affected. After the snapshot creation process starts, new data is not recorded in the snapshot. Only one snapshot can be created at a time.
- If some indexes selected during backup task creation are deleted before the backup task is started, the deleted indexes will not be backed up. If all indexes are deleted, the backup task fails to be executed.
- Ensure that the running status of all instances in the cluster is normal and can receive requests properly. To ensure successful backup, do not perform operations such as adding, deleting, stopping, or restarting Solr instances, stopping or restarting the Solr service, or stopping or restarting the cluster.
- If a large amount of data needs to be backed up in the cluster, back up data at the index level in batches. Otherwise, the backup takes a long time.
- If a backup task fails, log in to the backup directory of the target (**RemoteHDFS**), which is the value of **Target Path** for a backup to remote HDFS. Delete the subdirectory (*Backup task name_Data source_Task creation time*) corresponding to the backup task name to delete data that fails to be backed up.
- Before the backup, check whether the index to be backed up is in the green state and no shard is lost. Otherwise, the backup fails.

Prerequisites

- If data needs to be backed up to the remote HDFS, you have prepared a standby cluster for data backup. The authentication mode of the standby cluster is the same as that of the active cluster. For other backup modes, you do not need to prepare the standby cluster. Currently, Solr data can be backed up only to HDFS.
- For the Solr cluster in normal mode, service data cannot be backed up to HDFS in a cluster in security mode.
- If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.

- The HDFS in the standby cluster has sufficient space. You are advised to save backup files in a custom directory.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 Click **Create**.

Step 3 Set **Name** to the name of the backup task.

Step 4 Select the desired cluster from **Backup Object**.

Step 5 Set **Mode** to the type of the backup task.

Periodic indicates that the backup task is executed by the system periodically. **Manual** indicates that the backup task is executed manually.

Table 10-93 Periodic backup parameters

Parameter	Description
Started	Indicates the time when the task is started for the first time.
Period	Indicates the task execution interval. The options include **Hours** and **Days**.
Backup Policy	Indicates the volume of data to be backed up in each task execution. Only **Full backup every time** is supported.

Step 6 In **Configuration**, choose **Solr** > **Solr** under **Service data**.

Step 7 Set **Path Type** of **Solr** to a backup directory type.

The following backup directory types are supported:

RemoteHDFS: indicates that the backup files are stored in the HDFS directory of the standby cluster.

If you select this option, set the following parameters:

- **Destination NameService Name**: indicates the NameService name of the standby cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster.
- **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
- **Destination Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster.
- **Destination Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster.
- **Destination NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the standby cluster.

- **Target Path**: indicates the HDFS directory for storing standby cluster backup data. The storage path cannot be an HDFS hidden directory, such as a snapshot or recycle bin directory, or a default system directory, such as **/hbase** or **/user/hbase/backup**.
- **Maximum Number of Backup Copies**: indicates the number of backup file sets that can be retained in the backup directory.

Step 8 Set **Backup Content** to one or multiple collections to be backed up.

You can select backup data using either of the following methods:

- Adding a backup data file
  a. Click **Add**.
  b. Select the table to be backed up under **File Directory**, and click **Add** to add the table to **Backup Content**.
  c. Click **OK**.
- Selecting using regular expressions
  a. Click **Query Regular Expression**.
  b. Enter a slash (/) in the first text box. This root directory is not an actual directory but an internal Solr directory.
  c. Enter a regular expression in the second text box. Standard regular expressions are supported. For example, to get indexes containing **solr**, enter **.*solr.***. To get indexes starting with **solr**, enter **solr.***. To get indexes ending with **solr**, enter **.*solr**.
  d. Click **Refresh** to view the displayed tables in **Directory Name**.
  e. Click **Synchronize** to save the result.

  NOTE

  - When entering regular expressions, click + or — to add or delete an expression.
  - If the selected table or directory is incorrect, click **Clear Selected Node** to deselect it.

Step 9 Click **Verify** to check whether the backup task is configured correctly.

The possible causes of the verification failure are as follows:

- The destination active or standby NameNode IP address or NameService name is incorrect.
- The name of the index to be backed up does not exist in the cluster.

Step 10 Click **OK**.

Step 11 In the **Operation** column of the created task in the backup task list, click **More** and select **Back Up Now** to execute the backup task.

After the backup task is executed, the system automatically creates a subdirectory for each backup task in the backup directory. The format of the subdirectory name is *Backup task name_Data source_Task creation time*, and the subdirectory is used to save latest data source backup files. Each time a backup task is executed, a snapshot directory named *_Snapshot absolute seconds* is created in the directory.

When the number of snapshot directories is greater than the value of **Maximum Number of Backup Copies**, the earliest directory is automatically deleted.

----End

10.11.3 Recovering Data

10.11.3.1 Restoring Manager Data

Scenario

Manager data needs to be recovered in the following scenarios: data is modified or deleted unexpectedly and needs to be restored. After an administrator performs critical data adjustment in FusionInsight Manager, an exception occurs or the operation has not achieved the expected result. All modules are faulty and become unavailable.

System administrators can create a restoration task in FusionInsight Manager to recover Manager data. Only manual restoration tasks are supported.

NOTICE

- Data restoration can be performed only when the system version is consistent with that of data backup.
- To recover data when the service is running properly, you are advised to manually back up the latest management data before recovering data. Otherwise, the Manager data that is generated after the data backup and before the data restoration will be lost.

Impact on the System

- In the restoration process, the Controller needs to be restarted and FusionInsight Manager cannot be logged in or operated during the restart.
- During the restoration, the cluster needs to be restarted and cannot be accessed during the restart.
- After data restoration, the data, such as system configuration, user information, alarm information, and audit information, that is generated after the data backup and before the data restoration will be lost. This may result in data query failure or cluster access failure.
- After the Manager data is recovered, the system forces the LdapServer of each cluster to synchronize data from the OLadp.

Prerequisites

- To restore data from a remote HDFS, you need to prepare a standby cluster. If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, system mutual trust needs to be configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.

- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- The status of the OMS resources and the LdapServer instances of each cluster is normal. If the status is abnormal, data restoration cannot be performed.
- The status of the cluster hosts and services is normal. If the status is abnormal, data restoration cannot be performed.
- The cluster host topologies during data restoration and data backup are the same. If the topologies are different, data restoration cannot be performed and you need to back up data again.
- The services added to the cluster during data restoration and data backup are the same. If the topologies are different, data restoration cannot be performed and you need to back up data again.
- The upper-layer applications that depend on the cluster are stopped.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the **Operation** column of a specified task in the task list, choose **More** > **View History** to view the historical backup task execution records.

In the displayed window, locate a specified success record and click **View** in the **Backup Path** column to view the backup path information of the task and find the following information:

- **Backup Object** specifies the data source of the backup data.
- **Backup Path** specifies the full path where the backup files are saved.

  Select the correct item, and manually copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restore** > **Restoring Management**. On the displayed page, click **Create**.

Step 4 Set **Task Name** to the name of the restoration task.

Step 5 Set **Recovery Object** to **OMS**.

Step 6 In the **Restoration Configuration** area, select **OMS**.

Step 7 Set **Path Type** of **OMS** to a backup directory type.

The settings vary according to backup directory types:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node.

  If you select **LocalDir**, you also need to set **Source Path** to select the backup file to be restored, for example, *Version_Data source_Task execution time*.**tar.gz**.
- **LocalHDFS**: indicates that the backup files are stored in the HDFS directory of the current cluster.

  If you select **LocalHDFS**, set the following parameters:

  - **Source Path**: indicates the full path of the backup file in the HDFS, for example, *Backup path/Backup task name_Task creation time/Version_Data source_Task execution time***.tar.gz**.
  - **Cluster for Restoration**: Enter the name of the cluster used during restoration task execution.
  - **Source NameService Name**: indicates the NameService name that corresponds to the backup directory when a restoration task is executed. The default value is **hacluster**.
- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select **RemoteHDFS**, set the following parameters:
  - **Source NameService Name**: indicates the NameService name of the backup data cluster. You can enter the built-in NameService name of the remote cluster, for example, **haclusterX**, **haclusterX1**, **haclusterX2**, **haclusterX3**, or **haclusterX4**. You can also enter a configured NameService name of the remote cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Source NameNode IP Address**: indicates the NameNode service plane IP address of the standby cluster, supporting the active node or standby node.
  - **Source Path**: indicates the full path of HDFS directory for storing backup data of the standby cluster, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
  - **Source Cluster**: Select the cluster of the Yarn queue used by the recovery data.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.
- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol. If you select **NFS**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Source Path**: indicates the complete path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
- **CIFS**: indicates that backup files are stored in the NAS using the CIFS protocol. If you select **CIFS**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.

  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select **SFTP**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the server where the backup data is stored.
  - **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
  - **Username**: indicates the username for connecting to the server using the SFTP protocol.
  - **Password**: indicates the password for connecting to the server using the SFTP protocol.
  - **Source Path**: indicates the full path of the backup file on the backup server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
- **OBS**: indicates that backup files are stored in OBS.

  If you select **OBS**, set the following parameters:
  - **Source Path**: indicates the full OBS path of a backup file, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.

Step 8 Click **OK**.

Step 9 In the restoration task list, locate a created task and click **Start** in the **Operation** column to execute the restoration task.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be executed again.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to execute the task again.

Step 10 Log in to the active and standby management nodes as user **omm**.

Step 11 Run the following command to restart OMS:

sh ${BIGDATA_HOME}/om-server/om/sbin/restart-oms.sh

The command is run successfully if the following information is displayed:

```
start HA successfully.
```

Run **sh ${BIGDATA_HOME}/om-server/om/sbin/status-oms.sh** to check whether **HAAllResOK** of the management node is **Normal** and whether FusionInsight Manager can be logged in again. If yes, OMS is restarted successfully.

Step 12 On FusionInsight Manager, choose **Cluster** > **Services** > **KrbServer**. Click **More** and select **Synchronize Configurations**. In the dialog box displayed, click **OK**. Wait until the KrbServer configuration synchronization is complete.

Step 13 In the upper right corner of **Homepage**, click **More** and select **Synchronize Configurations**. In the dialog box displayed, click **OK**. Wait until the cluster configuration is successfully synchronized.

Step 14 In the upper right corner of **Homepage**, click **More** and select **Restart**. In the dialog box displayed, enter the password of the current login user and click **OK**. Wait until the cluster is successfully restarted.

----End

10.11.3.2 Restoring CDL Data

Scenario

CDL data needs to be restored in the following scenarios: Data is modified or deleted unexpectedly and needs to be restored. After an administrator performs major operations (such as upgrade and data adjustment) on CDL, an exception occurs or the expected result is not achieved. All modules are faulty and become unavailable. Data is migrated to a new cluster.

CDL metadata is stored in DBService and Kafka. A system administrator can create DBService and Kafka restoration tasks on FusionInsight Manager to restore CDL data. Only manual restoration tasks are supported.

NOTICE

- Data restoration can be performed only when the system version is consistent with that during data backup.
- To restore the data when services are normal, manually back up the latest management data first and then restore the data. Otherwise, the DBService and Kafka data that is generated after the data backup and before the data restoration will be lost.
- By default, MRS clusters use DBService to store metadata of Hive, Hue, Loader, Spark, Metadata, CDL, Redis, and Oozie. Restoring DBService data will restore the metadata of all these components.

Impact on the System

- After the data is restored, the data generated after the data backup and before the data restoration is lost.
- After the data is restored, the configurations of the components that depend on DBService may expire and these components need to be restarted.
- After the metadata is restored, the offset information stored on ZooKeeper by Kafka consumers is rolled back, resulting in repeated consumption.

Prerequisites

- If you need to restore data from a remote HDFS, prepare a standby cluster. If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust must be configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- The status of the active and standby DBService instances is normal. If the status is abnormal, data restoration cannot be performed.
- The Kafka service is disabled first, and then enabled upon data restoration.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the row where the specified backup task is located, choose **More** > **View History** in the **Operation** column to display the historical execution records of the backup task.

In the window that is displayed, select a success record and click **View** in the **Backup Path** column to view its backup path information and find the following information:

- **Backup Object**: indicates the backup data source.
- **Backup Path**: indicates the full path where backup files are stored.

  Select the correct path, and manually copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In the **Restoration Configuration** area, select **DBService** and **Kafka**.

NOTE

If multiple DBService or Kafka services are installed, select the DBService or Kafka services to be restored.

Step 8 Set **Path Type** of **DBService** to a backup directory type. For details about how to configure the parameters, see **Step 8**.

Step 9 Set **Path Type** of **Kafka** to a backup directory type. For details about how to configure the parameters, see **Step 8**.

Step 10 Click **OK**.

Step 11 In the restoration task list, locate the row where the created task is located, and click **Start** in the **Operation** column.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be executed again.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to execute the task again.

----End

10.11.3.3 Restoring Containers Metadata

Scenario

Restore Containers metadata in the following scenarios: Data is modified or deleted accidentally, or needs to be recovered; data exceptions occur or the change results are not as expected after major operations such as upgrade or data migration are performed on Containers; all modules are faulty and become unavailable; data is migrated to a new cluster.

You can create a restoration task on FusionInsight Manager to restore Containers metadata. Only manual restoration tasks are supported.

NOTICE

- Data can be restored only when the system version during data backup is the same as the current system version.
- To restore Containers metadata when services are running properly, manually back up the latest Containers metadata before restoration. Otherwise, the Containers metadata generated after the data backup and before the data restoration will be lost.
- You are advised to restore the metadata of Containers and RTDService at the same time. If only the RTDService metadata is backed up and restored, RTDService needs to be brought offline and then online. If only the Containers metadata is backed up and restored, the service management status may be inconsistent with the running status.
- After the Containers service is restored, if the prediction variables, model variables, and decision engines of the corresponding event sources have been brought online, you need to manually bring them online again after the restoration.

Impact on the System

- After the metadata is restored, the data generated after the data backup and before the data restoration is lost.
- After the metadata is restored, the upper-layer applications of Containers need to be restarted.

Prerequisites

- You have checked the path for storing Containers metadata backup files.
- You have prepared a standby cluster if you need to restore data remotely from HDFS. If the active cluster is deployed in security mode (with Kerberos authentication enabled) and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust must be configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode (with Kerberos authentication disabled), mutual trust is not required.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the **Operation** column of the specified task in the task list, click **More** and select **View History**.

In the window that is displayed, select a success record and click **View** in the **Backup Path** column to view its backup path information and find the following information:

- **Backup Object**: indicates the backup data source.
- **Backup Path**: indicates the full path for storing backup files.

  Select the correct path and copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In **Restoration Configuration**, select **Containers** under **Metadata and other data**.

Step 8 Set **Path Type** of **Containers** to a restoration directory type.

The configurations vary based on backup directory types:

- **LocalDir**: indicates that data is restored from the local disk of the active management node.

  If you select this option, you also need to set **Source Path**, which indicates the backup file to be restored, for example, *Backup task name_Data source_Task execution time*.**tar.gz**.
- **LocalHDFS**: indicates that the backup files are stored in the HDFS directory of the current cluster.

  If you select this option, you also need to configure the following parameters:

  – **Source Path**: indicates the full path for storing backup files in HDFS, for example, *Backup path/Backup task name_Task creation time/Version_Data source_Task execution time*.**tar.gz**.

  - **Source NameService Name**: indicates the NameService name that corresponds to the backup directory when a restoration task is executed. The default value is **hacluster**.

- **RemoteHDFS**: indicates that data is restored from the HDFS directory of the standby cluster.

  If you select this option, you also need to configure the following parameters:

  - **Source NameService Name**: indicates the NameService name of the backup data cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects an IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Source Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster.
  - **Source Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster.
  - **Source NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the destination cluster.
  - **Source Path**: indicates the full path of HDFS directory for storing backup data of the standby cluster, for example, *Backup path/Backup task name_Data source_Task creation time/Data source_Task execution time*.**tar.gz**.

Step 9 Click **OK**.

Step 10 In the restoration task list, locate the row where the created task is, and click **Start** in the **Operation** column. In the dialog box that is displayed, click **OK** to start the restoration task.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be re-executed.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to re-execute the task.

----End

10.11.3.4 Restoring ClickHouse Metadata

Scenario

ClickHouse metadata needs to be restored in the following scenarios: Data is modified or deleted unexpectedly and needs to be restored. After a user performs major operations (such as upgrade and migration) on ClickHouse, an exception occurs or the expected result is not achieved. The ClickHouse component is faulty and becomes unavailable. Data is migrated to a new cluster.

Users can create a ClickHouse restoration task on FusionInsight Manager. Only manual restoration tasks are supported.

NOTICE

- Data can be restored only when the system version during data backup is the same as the current system version.
- To restore ClickHouse metadata when the service is running properly, you are advised to manually back up the latest ClickHouse metadata before restoration. Otherwise, the ClickHouse metadata that is generated after the data backup and before the data restoration will be lost.

Impact on the System

- After the metadata is restored, the data generated after the data backup and before the data restoration is lost.
- After the metadata is restored, the ClickHouse upper-layer applications need to be started.

Prerequisites

- You have checked the path for storing ClickHouse metadata backup files.
- You have prepared a standby cluster if you need to restore data remotely from HDFS. If the active and standby clusters are deployed in security mode and they are not managed by the same FusionInsight Manager, mutual trust must be configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active and standby clusters are deployed in normal mode, no mutual trust is required.
- In the active/standby cluster, when restoring data from the remote HDFS to the local host, ensure that the value of **HADOOP_RPC_PROTECTION** of ClickHouse is the same as that of **hadoop.rpc.protection** of HDFS.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the **Operation** column of the specified task in the task list, choose **More** > **View History**.

In the window that is displayed, select a success record and click **View** in the **Backup Path** column to view its backup path information and find the following information:

- **Backup Object**: indicates the backup data source.
- **Backup Path**: indicates the full path for storing backup files.

  Select the correct path and copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In **Restoration Configuration**, select **ClickHouse** under **Metadata and other data**.

Step 8 Set **Path Type** of **ClickHouse** to a restoration directory type.

Table 10-94 Path for data restoration

Directory Type	Description
LocalDir	Indicates that data is restored from the local disk of the active management node. If you select this option, you also need to configure the following parameters: • **Source Path**: Enter the name of the backup file to be restored. To obtain the file name, log in to the active OMS node, go to the backup path copied in **Step 2**, and record the name of the metadata package, for example, *Backup task name_Data source_Task execution time*.**tar.gz**.
RemoteHDFS	Indicates that data is restored from the HDFS directory of the standby cluster. If you select this value option, you also need to configure the following parameters: • **Source NameService Name**: indicates the NameService name of the backup data cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster. • **IP Mode**: indicates the mode of the target IP address. The system automatically selects an IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**. • **Source Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster. • **Source Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster. • **Source NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the destination cluster. • **Source Path**: Enter the complete HDFS path for storing backup data of the standby cluster, that is, the backup path copied in **Step 2**, for example, */Backup path/Backup task name_Data source_Task creation time*. • **Logical Cluster**: Enter the ClickHouse logical cluster whose data has been backed up.

Directory Type	Description
OBS	Indicates that data is restored from OBS. If you select this option, you also need to configure the following parameters: • **Source Path**: indicates the full OBS path of a backup file, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time*.**tar.gz**.

The configurations vary based on backup directory types:

Step 9 Click **OK**.

Step 10 In the restoration task list, locate the row where the created task is, and click **Start** in the **Operation** column. In the dialog box that is displayed, click **OK** to start the restoration task.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be re-executed.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to re-execute the task.

Step 11 Choose **Cluster** > **Services** and start the ClickHouse service.

----End

10.11.3.5 Restoring ClickHouse Service Data

Scenario

ClickHouse data needs to be restored in the following scenarios: Data is modified or deleted unexpectedly and needs to be restored. After a user performs major operations (such as upgrade and migration) on ClickHouse, an exception occurs or the expected result is not achieved. All modules are faulty and become unavailable. Data is migrated to a new cluster.

You can create a restoration task on FusionInsight Manager to restore ClickHouse data. Only manual restoration tasks are supported.

The ClickHouse backup and restoration functions cannot identify the service and structure relationships of objects such as ClickHouse tables, indexes, and views. When executing backup and restoration tasks, you need to manage unified restoration points based on service scenarios to ensure proper service running.

NOTICE

- Data can be restored only when the system version during data backup is the same as the current system version.
- To restore the data when services are normal, manually back up the latest management data first and then restore the data. Otherwise, the ClickHouse data that is generated after the data backup and before the data restoration will be lost.

Impact on the System

- During data restoration, user authentication stops and users cannot create new connections.
- After the data is restored, the data generated after the data backup and before the data restoration is lost.
- After the data is restored, the ClickHouse upper-layer applications need to be started.

Prerequisites

- You have prepared a standby cluster if you need to restore data remotely from HDFS. If the active and standby clusters are deployed in security mode and they are not managed by the same FusionInsight Manager, mutual trust must be configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active and standby clusters are deployed in normal mode, no mutual trust is required.
- The time on the active and standby clusters must be the same, and the NTP service on the active and standby clusters uses the same time source.
- The database for storing restored data tables, the location for storing the data tables in HDFS, and the list of users who can access the restored data have been planned.
- The ClickHouse backup file save path is correct.
- The ClickHouse upper-layer applications are stopped.
- You have logged in to FusionInsight Manager. For details, see **Logging In to FusionInsight Manager**.
- In the active/standby cluster, when restoring data from the remote HDFS to the local host, ensure that the value of **HADOOP_RPC_PROTECTION** of ClickHouse is the same as that of **hadoop.rpc.protection** of HDFS.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the row where the specified backup task is located, choose **More** > **View History** in the **Operation** column to display the historical execution records of the backup task.

In the window that is displayed, select a success record and click **View** in the **Backup Path** column to view its backup path information and find the following information:

- **Backup Object**: indicates the backup data source.
- **Backup Path**: indicates the full path for storing backup files.
  Select the correct path and copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In **Restoration Configuration**, select **ClickHouse** under **Service data**.

Step 8 Set **Path Type** of **ClickHouse** to a restoration directory type.

Table 10-95 Path for data restoration

Directory Type	Description
RemoteHDFS	• Indicates that the backup files are stored in the HDFS directory of the standby cluster. If you select this option, you also need to configure the following parameters: – **Source NameService Name**: indicates the NameService name of the backup data cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster. – **IP Mode**: indicates the mode of the target IP address. The system automatically selects an IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**. – **Source Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster. – **Source Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster. – **Source NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the destination cluster. – **Source Path**: indicates the full path of the HDFS directory for storing backup data of the standby cluster. For details, see **Backup Path** obtained in **Step 2**. for example, *Backup path/Backup task name_Data source_Task creation time/*.

Directory Type	Description
OBS	Indicates that data is restored from OBS. If you select this option, you also need to configure the following parameters: • **Source Path**: indicates the full OBS path of a backup file, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time*.**tar.gz**.

Step 9 Click **OK**.

Step 10 In the restoration task list, locate a created task and click **Start** in the **Operation** column to execute the restoration task.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be re-executed.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to re-execute the task.

----End

10.11.3.6 Restoring DBService Data

Scenario

DBService data needs to be recovered in the following scenarios: data is modified or deleted unexpectedly and needs to be restored. After an administrator performs critical data adjustment in DBService, an exception occurs or the operation has not achieved the expected result. All modules are faulty and become unavailable. Data is migrated to a new cluster.

System administrators can create a recovery task in FusionInsight Manager to recover DBService data. Only manual restoration tasks are supported.

NOTICE

- Data restoration can be performed only when the system version is consistent with that of data backup.
- To recover data when the service is running properly, you are advised to manually back up the latest management data before recovering data. Otherwise, the DBService data that is generated after the data backup and before the data recovery will be lost.
- By default, MRS clusters use DBService to store metadata of Hive, Hue, Loader, Spark, Metadata, CDL, Redis, and Oozie. Restoring DBService data will restore the metadata of all these components.

Impact on the System

- After the data is restored, the data generated after the data backup and before the data restoration is lost.
- After the data is restored, the configurations of the components that depend on DBService may expire and these components need to be restarted.

Prerequisites

- To restore data from a remote HDFS, you need to prepare a standby cluster. If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- The status of the active and standby DBService instances is normal. If the status is abnormal, data restoration cannot be performed.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the **Operation** column of a specified task in the task list, choose **More** > **View History** to view the historical backup task execution records.

In the displayed window, locate a specified success record and click **View** in the **Backup Path** column to view the backup path information of the task and find the following information:

- **Backup Object** specifies the data source of the backup data.
- **Backup Path** specifies the full path where the backup files are saved.

  Select the correct item, and manually copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In the **Restoration Configuration** area, select **DBService**.

NOTE

If multiple DBServices are installed, select the DBServices to be restored.

Step 8 Set **Path Type** of **DBService** to a backup directory type.

The settings vary according to backup directory types:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node.

  If you select **LocalDir**, you also need to set **Source Path** to select the backup file to be restored, for example, *Version_Data source_Task execution time*.**tar.gz**.

- **LocalHDFS**: indicates that the backup files are stored in the HDFS directory of the current cluster.

  If you select **LocalHDFS**, set the following parameters:

  - **Source Path**: indicates the full path of the backup file in the HDFS, for example, *Backup path/Backup task name_Task creation time/Version_Data source_Task execution time*.**tar.gz**.
  - **Source NameService Name**: indicates the NameService name that corresponds to the backup directory when a restoration task is executed. The default value is **hacluster**.

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select **RemoteHDFS**, set the following parameters:

  - **Source NameService Name**: indicates the NameService name of the backup data cluster. You can enter the built-in NameService name of the remote cluster, for example, **haclusterX**, **haclusterX1**, **haclusterX2**, **haclusterX3**, or **haclusterX4**. You can also enter a configured NameService name of the remote cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Source NameNode IP Address**: indicates the NameNode service plane IP address of the standby cluster, supporting the active node or standby node.
  - **Source Path**: indicates the full path of HDFS directory for storing backup data of the standby cluster, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time*.**tar.gz**.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.

- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol.

  If you select **NFS**, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time*.**tar.gz**.

- **CIFS**: indicates that backup files are stored in the NAS using the CIFS protocol.

  If you select **CIFS**, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select **SFTP**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the server where the backup data is stored.
  - **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
  - **Username**: indicates the username for connecting to the server using the SFTP protocol.
  - **Password**: indicates the password for connecting to the server using the SFTP protocol.
  - **Source Path**: indicates the full path of the backup file on the backup server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
- **OBS**: indicates that backup files are stored in OBS.

  If you select **OBS**, set the following parameters:
  - **Source Path**: indicates the full OBS path of a backup file, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.

Step 9 Click **OK**.

Step 10 In the restoration task list, locate a created task and click **Start** in the **Operation** column to execute the restoration task.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be executed again.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to execute the task again.

----End

10.11.3.7 Restoring Flink Metadata

Scenario

Flink metadata needs to be restored in the following scenarios: Data is modified or deleted unexpectedly and needs to be restored. After an administrator performs major operations (such as upgrade and data adjustment) on Flink, an exception occurs or the expected result is not achieved. The Flink component is faulty and becomes unavailable. Data is migrated to a new cluster.

System administrators can create a Flink restoration task on FusionInsight Manager. Only manual restoration tasks are supported.

NOTICE

- Data restoration can be performed only when the system version is consistent with that during data backup.
- To restore Flink metadata when the service is running properly, you are advised to manually back up the latest Flink metadata before restoration. Otherwise, the Flink metadata that is generated after the data backup and before the data restoration will be lost.
- Flink metadata restoration and service data restoration cannot be performed at the same time. Otherwise, service data restoration fails. You are advised to restore service data after metadata restoration is complete.

Impact on the System

- Before restoring the metadata, you need to stop the Flink service. During this period, all upper-layer applications are affected and cannot work properly.
- After the metadata is restored, the data generated after the data backup and before the data restoration is lost.
- After the metadata is restored, the Flink upper-layer applications of Solr need to be started.

Prerequisites

- You have checked the path for storing Flink metadata backup files.
- The Flink service has been stopped before its metadata is restored.
- If you need to restore data from a remote HDFS, prepare a standby cluster. If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the **Operation** column of the specified task in the task list, choose **More** > **View History**.

In the displayed window, select a success record and click **View** in the **Backup Path** column to view its backup path information and find the following information:

- **Backup Object** specifies the data source of the backup data.
- **Backup Path** specifies the full path where the backup files are saved.

  Select the correct path, and manually copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In **Restoration Configuration**, select **Flink** under **Metadata and other data**.

Step 8 Set **Path Type** of **Flink** to a restoration directory type.

The settings vary according to backup directory types:

- **LocalDir**: indicates that data is restored from the local disk of the active management node.

  If you select **LocalDir**, you also need to set **Source Path** to select the backup file to be restored, for example, *Backup task name_Data source_Task execution time***.tar.gz**.
- **LocalHDFS**: indicates that the backup files are stored in the HDFS directory of the current cluster.

  If you select **LocalHDFS**, set the following parameters:

  – **Source Path**: indicates the full path of the backup file in the HDFS, for example, *Backup path/Backup task name_Task creation time/Version_Data source_Task execution time***.tar.gz**.

  – **Source NameService Name**: indicates the NameService name that corresponds to the backup directory when a restoration task is executed.
- **RemoteHDFS**: indicates that data is restored from the HDFS directory of the standby cluster.

  If you select **RemoteHDFS**, set the following parameters:

  – **Source NameService Name**: indicates the NameService name of the backup data cluster. You can enter the built-in NameService name of the remote cluster, for example, **haclusterX**, **haclusterX1**, **haclusterX2**, **haclusterX3**, or **haclusterX4**. You can also enter a configured NameService name of the remote cluster.

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Source NameNode IP Address**: indicates the NameNode service plane IP address of the standby cluster, supporting the active node or standby node.
  - **Source Path**: indicates the full path of HDFS directory for storing backup data of the standby cluster, for example, *Backup path/Backup task name_Data source_Task creation time/Data source_Task execution time*.**tar.gz**.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the source cluster.

Step 9 Click **OK**.

Step 10 In the restoration task list, locate the row where the created task is located, and click **Start** in the **Operation** column. In the displayed dialog box, click **OK** to start the restoration task.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be executed again.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to execute the task again.

Step 11 Choose **Cluster** > **Services** and start the Flink service.

----End

10.11.3.8 Restoring HBase Metadata

Scenario

To ensure HBase metadata security (including tableinfo files and HFiles) or before a major operation on HBase system tables (such as upgrade or migration), you need to back up HBase metadata to prevent HBase service unavailability caused by HBase system table directory or file damages. The backup data can be used to recover the system if an exception occurs or the operation has not achieved the expected result, minimizing the adverse impacts on services.

System administrators can create a recovery task in FusionInsight Manager to recover HBase metadata. Only manual restoration tasks are supported.

NOTICE

- Data restoration can be performed only when the system version is consistent with that during data backup.
- To recover data when the service is running properly, you are advised to manually back up the latest management data before recovering data. Otherwise, the HBase data that is generated after the data backup and before the data recovery will be lost.
- It is recommended that a data restoration task restore the metadata of only one component to prevent the data restoration of other components from being affected by stopping a service or instance. If data of multiple components is restored at the same time, data restoration may fail.

  HBase metadata cannot be restored at the same time as NameNode metadata. As a result, data restoration fails.

Impact on the System

- Before restoring the metadata, you need to stop the HBase service, during which the HBase upper-layer applications are unavailable.
- After the metadata is restored, the data generated after the data backup and before the data restoration is lost.
- After the metadata is restored, the upper-layer applications of HBase need to be started.

Prerequisites

- If you need to restore data from a remote HDFS, prepare a standby cluster. If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- You have checked the path for storing HBase metadata backup files.
- The HBase service has been stopped before its metadata is restored.
- You have logged in to FusionInsight Manager. For details, see **Logging In to FusionInsight Manager**.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the **Operation** column of a specified task in the task list, choose **More** > **View History** to view the historical backup task execution records.

In the displayed window, locate a specified success record and click **View** in the **Backup Path** column to view the backup path information of the task and find the following information:

- **Backup Object** specifies the data source of the backup data.
- **Backup Path** specifies the full path where the backup files are saved.

  Select the correct item, and manually copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In **Restoration Configuration**, select **HBase** under **Metadata and other data**.

NOTE

If multiple HBase services are installed, select the HBase services to be restored.

Step 8 Set **Path Type** of **HBase** to a backup directory type.

The settings vary according to backup directory types:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node.

  If you select **LocalDir**, you also need to set **Source Path** to select the backup file to be restored, for example, *Version_Data source_Task execution time*.**tar.gz**.
- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select **RemoteHDFS**, set the following parameters:

  - **Source NameService Name**: indicates the NameService name of the backup data cluster. You can enter the built-in NameService name of the remote cluster, for example, **haclusterX**, **haclusterX1**, **haclusterX2**, **haclusterX3**, or **haclusterX4**. You can also enter a configured NameService name of the remote cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Source NameNode IP Address**: indicates the NameNode service plane IP address of the standby cluster, supporting the active node or standby node.
  - **Source Path**: indicates the full path of HDFS directory for storing backup data of the standby cluster, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time*.**tar.gz**.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.
- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol.

  If you select **NFS**, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
- **CIFS**: indicates that backup files are stored in NAS using the CIFS protocol.

  If you select **CIFS**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select **SFTP**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the server where the backup data is stored.
  - **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
  - **Username**: indicates the username for connecting to the server using the SFTP protocol.
  - **Password**: indicates the password for connecting to the server using the SFTP protocol.
  - **Source Path**: indicates the full path of the backup file on the backup server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
- **OBS**: indicates that backup files are stored in OBS.

  If you select **OBS**, set the following parameters:
  - **Source Path**: indicates the full OBS path of a backup file, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.

Step 9 Click **OK**.

Step 10 In the restoration task list, locate a created task and click **Start** in the **Operation** column to execute the restoration task.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be executed again.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to execute the task again.

----End

10.11.3.9 Restoring HBase Service Data

Scenario

HBase data needs to be recovered in the following scenarios: data is modified or deleted unexpectedly and needs to be restored. After an administrator performs critical data adjustment in HBase, an exception occurs or the operation has not achieved the expected result. All modules are faulty and become unavailable. Data is migrated to a new cluster.

System administrators can create a recovery task in FusionInsight Manager to recover HBase data. Only manual restoration tasks are supported.

NOTICE

- Data restoration can be performed only when the system version is consistent with that during data backup.
- To recover data when the service is running properly, you are advised to manually back up the latest management data before recovering data. Otherwise, the HBase data that is generated after the data backup and before the data recovery will be lost.
- HBase service data and HBase/HDFS metadata cannot be restored at the same time. Otherwise, metadata restoration fails. Restore service data after metadata restoration is complete.

Impact on the System

- During the data recovery process, the system disables the HBase table to be recovered and the table cannot be accessed in this moment. The data recovery process takes several minutes, during which the HBase upper-layer applications are unavailable.
- During data restoration, user authentication stops and users cannot create new connections.
- After the data is restored, the data generated after the data backup and before the data restoration is lost.
- After the data is recovered, the HBase upper-layer applications need to be started.

Prerequisites

- If you need to restore data from a remote HDFS, prepare a standby cluster. If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- The directory for saving the backup file has been checked.
- The HBase upper-layer applications have been stopped.
- You have logged in to FusionInsight Manager. For details, see **Logging In to FusionInsight Manager**.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the **Operation** column of a specified task in the task list, choose **More** > **View History** to view historical backup task execution records.

In the displayed window, locate a specified success record and click **View** in the **Backup Path** column to view the backup path information of the task and find the following information:

- **Backup Object** specifies the data source of the backup data.
- **Backup Path** specifies the full path where the backup files are saved.

  Select the correct item, and manually copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In **Restoration Configuration**, select **HBase** under **Service Data**.

Step 8 Set **Path Type** of **HBase** to a backup directory type.

The following backup directory types are supported:

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster. If you select **RemoteHDFS**, set the following parameters:
  - **Source NameService Name**: indicates the NameService name of the backup data cluster. You can enter the built-in NameService name of the remote cluster, for example, **haclusterX**, **haclusterX1**, **haclusterX2**,

haclusterX3, or **haclusterX4**. You can also enter a configured NameService name of the remote cluster.

- **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
- **Source NameNode IP Address**: indicates the NameNode service plane IP address of the standby cluster, supporting the active node or standby node.
- **Source Path**: indicates the full path of the backup file in the HDFS, for example, *Backup path/xxx/Backup task name_Data source_Task creation time*. To obtain the backup path, locate the row that contains the target backup task in the backup management list, click **More** > **View History** in the **Operation** column, and click **View** in the **Backup Path** column.
- **Queue Name**: indicates the name of the Yarn queue used for backup task execution.
- **Recovery Point List**: Click **Refresh** and select an HDFS directory that has been backed up in the standby cluster.
- **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
- **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.

- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol. If you select **NFS**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/xxx/Backup task name_Data source_Task creation time*. To obtain the backup path, locate the row that contains the target backup task in the backup management list, click **More** > **View History** in the **Operation** column, and click **View** in the **Backup Path** column.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution.
  - **Recovery Point List**: Click **Refresh** and select an HDFS directory that has been backed up in the standby cluster.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
- **CIFS**: indicates that backup files are stored in the NAS using the CIFS protocol. If you select **CIFS**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.

  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/xxx/Backup task name_Data source_Task creation time*. To obtain the backup path, locate the row that contains the target backup task in the backup management list, click **More** > **View History** in the **Operation** column, and click **View** in the **Backup Path** column.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution.
  - **Recovery Point List**: Click **Refresh** and select an HDFS directory that has been backed up in the standby cluster.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select **SFTP**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the server where the backup data is stored.
  - **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
  - **Username**: indicates the username for connecting to the server using the SFTP protocol.
  - **Password**: indicates the password for connecting to the server using the SFTP protocol.
  - **Source Path**: indicates the full path of the backup file on the backup server, for example, *Backup path/xxx/Backup task name_Data source_Task creation time*. To obtain the backup path, locate the row that contains the target backup task in the backup management list, click **More** > **View History** in the **Operation** column, and click **View** in the **Backup Path** column.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution.
  - **Recovery Point List**: Click **Refresh** and select an HDFS directory that has been backed up in the standby cluster.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.

- **OBS**: indicates that backup files are stored in OBS.

  If you select this option, you also need to configure the following parameters:

  - **Source Path**: indicates the full OBS path of a backup file, for example, *Backup path/xxx/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution.
  - **Recovery Point List**: Click **Refresh** and select an OBS directory that has been backed up.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.

Step 9 Set **Backup Data** column in **Data Configuration** to one or multiple backup data sources to be recovered. In the **Target Namespace** column, specify the target naming space after backup data recovery.

You are advised to set **Target Namespace** to a location that is different from the backup naming space.

Step 10 Set **Force recovery** to **true**, which indicates to forcibly recover all backup data when a data table with the same name already exists. If the data table contains new data added after backup, the new data will be lost after the data recovery. If you set the parameter to **false**, the restoration task is not executed if a data table with the same name exists.

Step 11 Click **Verify** to check whether the restoration task is configured correctly.

- If the queue name is incorrect, the verification fails.
- If the specified naming space does not exist, the verification fails.
- If the forcible overwrite conditions are not met, the verification fails.

Step 12 Click **OK** to save the settings.

Step 13 In the restoration task list, locate a created task and click **Start** in the **Operation** column to execute the restoration task.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be executed again.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to execute the task again.

Step 14 Check whether HBase data is restored in an environment where HBase is newly installed or reinstalled.

- If yes, the administrator needs to set new permission for roles on FusionInsight Manager based on the original service plan.
- If no, no further operation is required.

----End

10.11.3.10 Restoring Elasticsearch Service Data

Scenario

Elasticsearch service data needs to be recovered in the following scenarios: Data is modified or deleted unexpectedly and needs to be restored; after an administrator performs a critical operation (such as upgrade or critical data adjustment) on Elasticsearch, an exception occurs or the operation has not achieved the expected result, causing all modules to be faulty; data is migrated to a new cluster.

This section describes how to create an Elasticsearch service data restoration task on FusionInsight Manager. The data can only be manually restored.

NOTICE

- Data can be restored only when the system version during data backup is the same as the current system version.
- To restore Elasticsearch service data when services are normal, manually back up the latest service data first and then restore the service data. Otherwise, the Elasticsearch service data that is generated after the data backup and before the data recovery will be lost.
- The number of index shards to be restored must be the same as the number of index shards in the snapshot.
- During the restoration task execution, the indexes to be restored are automatically closed. After the restoration task is complete, the indexes are automatically opened. If the indexes to be restored do not exist, the indexes are automatically created. Therefore, service operations of the indexes may be affected during the restoration task execution.
- The Elasticsearch service data restoration needs to invoke the snapshot interface through the EsNode1 instance. Therefore, ensure that all EsNode1 instances in the cluster are in good health status and can receive requests normally. To ensure successful restoration, do not perform operations such as adding, deleting, stopping, or restarting Elasticsearch instances, stopping or restarting the Elasticsearch service, or stopping or restarting the cluster.

Impact on the System

- After the data is restored, the data generated after the data backup and before the data restoration is lost.
- After the data is recovered, the Elasticsearch upper-layer applications need to be started.

Prerequisites

- The directory for storing the Elasticsearch backup files has been checked.
- The Elasticsearch upper-layer applications have been stopped.
- You have prepared a standby cluster if you need to restore data remotely from HDFS. If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-**

Manager Mutual Trust Between Clusters. If the active cluster is deployed in normal mode, no mutual trust is required.

- The time on the active and standby clusters must be the same, and the NTP service on the active and standby clusters uses the same time source.

Procedure

Step 1 Log in to FusionInsight Manager, and choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the **Operation** column of the specified task in the task list, choose **More** > **View History**.

In the window that is displayed, select a success record and click **View** in the **Backup Path** column to view its backup path information and find the following information:

- **Backup Object**: indicates the backup data source.
- **Backup Path**: indicates the full path for storing backup files.

  Select the correct path and copy the full path of backup files in **Backup Path**.

Step 3 Choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In the **Restoration Configuration** area, select **Elasticsearch** under **Service data**.

Step 8 In the displayed **Elasticsearch** area, set **Path Type** to the restoration directory type.

The following restoration directory types are supported:

- **RemoteHDFS**: indicates that data is restored from the HDFS directory of the standby cluster.

  If you select this option, you also need to configure the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects an IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Source NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster.
  - **Source Path**: indicates the full path for storing backup files in HDFS, for example, *Backup path/Backup task name_Data source_Task creation time*.
  - **Restoration Point List**: Click **Refresh** and select an Elasticsearch snapshot that has been backed up in the standby cluster.
- **NFS**: indicates that backup files are obtained from the NAS through the NFS protocol. If you select this option, you also need to configure the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects an IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.

  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time*.
  - **Restoration Point List**: Click **Refresh** and select an Elasticsearch snapshot that has been backed up in the NAS.

Step 9 In the **Data Configuration** area, select one or more pieces of backed up data for **Backup Object** based on service requirements.

NOTE

If the **.security_info** or **.index_owner_info** index is selected, disable it in advance. Otherwise, the restoration task may fail.

Step 10 Specify **Force recovery**. The value **false** does not take effect. All backup data is forcibly restored when there are indexes with the same name. If the index contains data added after the backup, the new data will be lost after the data restoration.

Step 11 Click **Verify** to check whether the restoration task is configured correctly.

- If the specified directory to be recovered does not exist, the verification fails.
- If the forcible replacement conditions are not met, the verification fails.

Step 12 Click **OK**.

Step 13 In the restoration task list, locate a created task and click **Start** in the **Operation** column to execute the restoration task.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be re-executed.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to re-execute the task.

----End

10.11.3.11 Restoring MOTService Service Data

Scenario

Restore MOTService data in the following scenarios: Data is modified or deleted accidentally, or needs to be recovered; data exceptions occur or the change results are not as expected after major operations such as upgrade or data modification are performed on MOTService; all modules are faulty and become unavailable; data is migrated to a new cluster.

Users can create MOTService restoration tasks on FusionInsight Manager to restore MOTService data. Only manual restoration tasks are supported.

NOTICE

- Data can be restored only when the system version during data backup is the same as the current system version.
- To restore data when services are normal, manually back up the latest management data before restoring data. Otherwise, the MOTService data generated after the data backup and before the data restoration will be lost.

Impact on the System

- During data restoration, user authentication stops and users cannot create new connections.
- After the data is restored, the data generated after the data backup and before the data restoration is lost.
- After the data is restored, the upper-layer applications of MOTService need to be restarted.

Prerequisites

- You have prepared a standby cluster if you need to restore data remotely from HDFS. If the active cluster is deployed in security mode (with Kerberos authentication enabled) and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust must be configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode (with Kerberos authentication disabled), mutual trust is not required.
- The time on the active and standby clusters must be the same, and the NTP service on the active and standby clusters uses the same time source.
- The database for storing restored data tables, the location for storing the data tables in HDFS, and the list of users who can access the restored data have been planned.
- The location for storing MOTService backup files is correct.
- The upper-layer applications of MOTService have been stopped.
- You have logged in to FusionInsight Manager by referring to **Logging In to FusionInsight Manager**.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the **Operation** column of a specified task in the task list, click **More** and select **View History** to view historical execution records of backup tasks.

In the window that is displayed, select a success record and click **View** in the **Backup Path** column to view its backup path information and find the following information:

- **Backup Object**: indicates the backup data source.
- **Backup Path**: indicates the full path for storing backup files.

  Select the correct path and copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In **Restoration Configuration**, select **MOTService** under **Service data**.

Step 8 Set **Path Type** of **MOTService** to a backup directory type.

Currently, only the **RemoteHDFS** type is available.

RemoteHDFS: indicates that backup files are stored in HDFS of the standby cluster. If you select this option, you also need to configure the following parameters:

- **Source NameService Name**: indicates the NameService name of the backup data cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster.
- **IP Mode**: indicates the mode of the target IP address. The system automatically selects an IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
- **Source Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster.
- **Source Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster.
- **Source NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the destination cluster.
- **Source Path**: indicates the full path of the HDFS directory for storing backup data of the standby cluster. For details, see **Backup Path** obtained in **Step 2**, for example, *Backup path/Backup task name_Data source_Task creation time/*.

Step 9 Click **OK**.

Step 10 Choose **Cluster** > **Services** > **MOTService**. On the **Dashboard** page that is displayed, click **Stop** to stop the MOTService service as prompted.

Step 11 In the restoration task list, locate a created task and click **Start** in the **Operation** column to execute the restoration task. After the restoration task is complete, manually start the MOTService service.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be re-executed.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to re-execute the task.

----End

10.11.3.12 Restoring NameNode Data

Scenario

NameNode data needs to be recovered in the following scenarios: data is modified or deleted unexpectedly and needs to be restored. After an administrator performs

critical data adjustment in NameNode, an exception occurs or the operation has not achieved the expected result. All modules are faulty and become unavailable. Data is migrated to a new cluster.

System administrators can create a recovery task in FusionInsight Manager to recover NameNode data. Only manual restoration tasks are supported.

NOTICE

- If HDFS service data also needs to be restored, restore HDFS service data first and then NameNode data.
- Data restoration can be performed only when the system version is consistent with that during data backup.
- To recover data when the service is running properly, you are advised to manually back up the latest management data before recovering data. Otherwise, the NameNode data that is generated after the data backup and before the data recovery will be lost.
- It is recommended that a data restoration task restore the metadata of only one component to prevent the data restoration of other components from being affected by stopping a service or instance. If data of multiple components is restored at the same time, data restoration may fail.

  HBase metadata cannot be restored at the same time as NameNode metadata. As a result, data restoration fails.

Impact on the System

- After the data is restored, the data generated after the data backup and before the data restoration is lost.
- After the data is recovered, the NameNode needs to be restarted and is unavailable during the restart.
- After data is restored, metadata and service data may not be matched, the HDFS enters the security mode, and the HDFS service fails to be started. .

Prerequisites

- If you need to restore data from a remote HDFS, prepare a standby cluster. If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- You have logged in to FusionInsight Manager. For details, see **Logging In to FusionInsight Manager**.
- On FusionInsight Manager, all the NameNode role instances whose data is to be recovered are stopped. Other HDFS role instances must keep running. After

data is recovered, the NameNode role instances need to be restarted. The NameNode role instances cannot be accessed during the restart.

- The NameNode backup files are stored ***Data path*/LocalBackup/** on the active management node.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **HDFS**. On the displayed page, click **Instance** then **NameNode** to check whether the NameNode instances whose data is to be restored are stopped. If they are not, stop them.

Step 2 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 3 In the **Operation** column of a specified task in the task list, choose **More** > **View History** to view historical backup task execution records.

In the displayed window, locate a specified success record and click **View** in the **Backup Path** column to view the backup path information of the task and find the following information:

- **Backup Object** specifies the data source of the backup data.
- **Backup Path** specifies the full path where the backup files are saved.

  Select the correct item, and manually copy the full path of backup files in **Backup Path**.

Step 4 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 5 Click **Create**.

Step 6 Set **Task Name** to the name of the restoration task.

Step 7 Select the desired cluster from **Recovery Object**.

Step 8 In the **Restoration Configuration** area, select **NameNode**.

Step 9 Set **Path Type** of **NameNode** to a backup directory type.

The settings vary according to backup directory types:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node.

  If you select **LocalDir**, set the following parameters:

  - **Source Path**: indicates the full path of the backup file on the local disk, for example, *Backup path/Backup task name_Task creation time/Version_Data source_Task execution time***.tar.gz**.
  - **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select **RemoteHDFS**, set the following parameters:

  - **Source NameService Name**: indicates the NameService name of the backup data cluster. You can enter the built-in NameService name of the remote cluster, for example, **haclusterX**, **haclusterX1**, **haclusterX2**,

haclusterX3, or **haclusterX4**. You can also enter a configured NameService name of the remote cluster.

- **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
- **Source NameNode IP Address**: indicates the NameNode service plane IP address of the standby cluster, supporting the active node or standby node.
- **Source Path**: indicates the full path of HDFS directory for storing backup data of the standby cluster, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
- **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.
- **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.

- **NFS**: indicates that backup files are stored in the NAS using the NFS protocol. If you select **NFS**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
  - **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
- **CIFS**: indicates that backup files are stored in the NAS using the CIFS protocol. If you select **CIFS**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
  - **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

If you select **SFTP**, set the following parameters:

- **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
- **Server IP Address**: indicates the IP address of the server where the backup data is stored.
- **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
- **Username**: indicates the username for connecting to the server using the SFTP protocol.
- **Password**: indicates the password for connecting to the server using the SFTP protocol.
- **Source Path**: indicates the full path of the backup file on the backup server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
- **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.

- **OBS**: indicates that backup files are stored in OBS.

  If you select **OBS**, set the following parameters:

  - **Source Path**: indicates the full OBS path of a backup file, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
  - **NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.

Step 10 Click **OK**.

Step 11 In the restoration task list, locate a created task and click **Start** in the **Operation** column to execute the restoration task.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be executed again.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to execute the task again.

Step 12 On FusionInsight Manager, choose **Cluster** > **Services** > **HDFS**. Click **More** and select **Restart Service**.

On the displayed page, enter the password of the administrator who has logged in for authentication and click **OK**. After the system displays "Operation succeeded", click **Finish**. The service is started successfully.

----End

10.11.3.13 Restoring HDFS Service Data

Scenario

HDFS data needs to be recovered in the following scenarios: data is modified or deleted unexpectedly and needs to be restored. After an administrator performs

critical data adjustment in the HDFS, an exception occurs or the operation has not achieved the expected result. All modules are faulty and become unavailable. Data is migrated to a new cluster.

System administrators can create a recovery task in FusionInsight Manager to recover HDFS data. Only manual restoration tasks are supported.

NOTICE

- Data restoration can be performed only when the system version is consistent with that during data backup.
- To recover data when the service is running properly, you are advised to manually back up the latest management data before recovering data. Otherwise, the HDFS data that is generated after the data backup and before the data recovery will be lost.
- The HDFS restoration operation cannot be performed for the directories used by running Yarn tasks, for example, **/tmp/logs**, **/tmp/archived**, and **/tmp/hadoop-yarn/staging**. Otherwise, data restoration using Distcp tasks fails due to file loss.

Impact on the System

- During data restoration, user authentication stops and users cannot create new connections.
- After the data is restored, the data generated after the data backup and before the data restoration is lost.
- After the data is recovered, the HDFS upper-layer applications need to be started.

Prerequisites

- If you need to restore data from a remote HDFS, prepare a standby cluster. If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- The HDFS backup file save path is correct.
- The HDFS upper-layer applications are stopped.
- You have logged in to FusionInsight Manager. For details, see **Logging In to FusionInsight Manager**.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the **Operation** column of a specified task in the task list, choose **More** > **View History** to view historical backup task execution records.

In the displayed window, locate a specified success record and click **View** in the **Backup Path** column to view the backup path information of the task and find the following information:

- **Backup Object** specifies the data source of the backup data.
- **Backup Path** specifies the full path where the backup files are saved.

  Select the correct item, and manually copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In **Restoration Configuration**, select **HDFS** under **Service Data**.

Step 8 Set **Path Type** of **HDFS** to a backup directory type.

The following backup directory types are supported:

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select **RemoteHDFS**, set the following parameters:

  - **Source NameService Name**: indicates the NameService name of the backup data cluster. You can enter the built-in NameService name of the remote cluster, for example, **haclusterX**, **haclusterX1**, **haclusterX2**, **haclusterX3**, or **haclusterX4**. You can also enter a configured NameService name of the remote cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Source NameNode IP Address**: indicates the NameNode service plane IP address of the standby cluster, supporting the active node or standby node.
  - **Source Path**: indicates the full path of HDFS directory for storing backup data of the standby cluster, for example, *Backup path/Backup task name_Data source_Task creation time*.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution.
  - **Recovery Point List**: Click **Refresh** and select an HDFS directory that has been backed up in the standby cluster.
  - **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.

- **NFS**: indicates that backup files are stored in NAS using the NFS protocol. If you select **NFS**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time*.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution.
  - **Recovery Point List**: Click **Refresh** and select an HDFS directory that has been backed up in the standby cluster.
  - **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
- **CIFS**: indicates that backup files are stored in NAS using the CIFS protocol. If you select **CIFS**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time*.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution.
  - **Recovery Point List**: Click **Refresh** and select an HDFS directory that has been backed up in the standby cluster.
  - **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select **SFTP**, set the following parameters:

- **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
- **Server IP Address**: indicates the IP address of the server where the backup data is stored.
- **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
- **Username**: indicates the username for connecting to the server using the SFTP protocol.
- **Password**: indicates the password for connecting to the server using the SFTP protocol.
- **Source Path**: indicates the full path of the backup file on the backup server, for example, *Backup path/Backup task name_Data source_Task creation time*.
- **Queue Name**: indicates the name of the Yarn queue used for backup task execution.
- **Recovery Point List**: Click **Refresh** and select an HDFS directory that has been backed up in the standby cluster.
- **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
- **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
- **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.

Step 9 In the **Backup Data** column of the **Data Configuration** page, select one or more pieces of backup data that needs to be restored based on service requirements. In the **Target Path** column, specify the target location after backup data restoration.

You are advised to set **Target Path** to a new path that is different from the backup path.

Step 10 Click **Verify** to check whether the restoration task is configured correctly.

- If the queue name is incorrect, the verification fails.
- If the specified directory to be restored does not exist, the verification fails.

Step 11 Click **OK**.

Step 12 In the restoration task list, locate a created task and click **Start** in the **Operation** column to execute the restoration task.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be executed again.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to execute the task again.

----End

10.11.3.14 Restoring Hive Service Data

Scenario

Hive data needs to be recovered in the following scenarios: data is modified or deleted unexpectedly and needs to be restored. After an administrator performs critical data adjustment in the Hive, an exception occurs or the operation has not achieved the expected result. All modules are faulty and become unavailable. Data is migrated to a new cluster.

System administrators can create a recovery task in FusionInsight Manager to recover Hive data. Only manual restoration tasks are supported.

Hive backup and restoration cannot identify the service and structure relationships of objects such as Hive tables, indexes, and views. When executing backup and restoration tasks, you need to manage unified restoration points based on service scenarios to ensure proper service running.

NOTICE

- Data restoration can be performed only when the system version is consistent with that during data backup.
- To recover data when the service is running properly, you are advised to manually back up the latest management data before recovering data. Otherwise, the Hive data that is generated after the data backup and before the data recovery will be lost.
- To prevent stopping a service or instance from affecting data restoration of other components, do not restore Hive service data and HDFS/HBase metadata at the same time. Otherwise, Hive service data restoration fails.

Impact on the System

- During data restoration, user authentication stops and users cannot create new connections.
- After the data is restored, the data generated after the data backup and before the data restoration is lost.
- After the data is recovered, the Hive upper-layer applications need to be started.

Prerequisites

- If you need to restore data from a remote HDFS, prepare a standby cluster. If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.

- The database for storing restored data tables, the HDFS save path of data tables, and the list of users who can access restored data are planned.
- The Hive backup file save path is correct.
- The Hive upper-layer applications are stopped.
- You have logged in to FusionInsight Manager. For details, see **Logging In to FusionInsight Manager**.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the **Operation** column of a specified task in the task list, choose **More** > **View History** to view historical backup task execution records.

In the displayed window, locate a specified success record and click **View** in the **Backup Path** column to view the backup path information of the task and find the following information:

- **Backup Object** specifies the data source of the backup data.
- **Backup Path** specifies the full path where the backup files are saved.

  Select the correct item, and manually copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In the **Restoration Configuration** area, select **Hive**.

Step 8 Set **Path Type** of **Hive** to a backup directory type.

The following backup directory types are supported:

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster. If you select **RemoteHDFS**, set the following parameters:
  - **Source NameService Name**: indicates the NameService name of the backup data cluster. You can enter the built-in NameService name of the remote cluster, for example, **haclusterX**, **haclusterX1**, **haclusterX2**, **haclusterX3**, or **haclusterX4**. You can also enter a configured NameService name of the remote cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Source NameNode IP Address**: indicates the NameNode service plane IP address of the standby cluster, supporting the active node or standby node.

  - **Source Path**: indicates the full path of HDFS directory for storing backup data of the standby cluster, for example, *Backup path/Backup task name_Data source_Task creation time*.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution.
  - **Recovery Point List**: Click **Refresh** and select a Hive backup file set that has been backed up in the standby cluster.
  - **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
- **NFS**: indicates that backup files are stored in NAS using the NFS protocol. If you select **NFS**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time*.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution.
  - **Recovery Point List**: Click **Refresh** and select a Hive backup file set that has been backed up in the standby cluster.
  - **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
- **CIFS**: indicates that backup files are stored in NAS using the CIFS protocol. If you select **CIFS**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time*.

  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution.
  - **Recovery Point List**: Click **Refresh** and select a Hive backup file set that has been backed up in the standby cluster.
  - **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **100**.
- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select **SFTP**, set the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the server where the backup data is stored.
  - **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
  - **Username**: indicates the username for connecting to the server using the SFTP protocol.
  - **Password**: indicates the password for connecting to the server using the SFTP protocol.
  - **Source Path**: indicates the full path of the backup file on the backup server, for example, *Backup path/Backup task name_Data source_Task creation time*.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution.
  - **Recovery Point List**: Click **Refresh** and select an HDFS directory that has been backed up in the standby cluster.
  - **Target NameService Name**: indicates the NameService name of the backup directory. The default value is **hacluster**.
  - **Maximum Number of Maps**: indicates the maximum number of maps in a MapReduce task. The default value is **20**.
  - **Maximum Bandwidth of a Map (MB/s)**: indicates the maximum bandwidth of a map. The default value is **1**.

Step 9 Set **Backup Data** in the **Data Configuration** to one or multiple backup data sources to be recovered based on service requirements. In the **Target Database** and **Target Path** columns, specify the target database and file save path after backup data recovery.

Configuration restrictions:

- Data can be restored to the original database, but data tables must be stored in a new path that is different from the backup path.
- To restore Hive index tables, select the Hive data tables that correspond to the Hive index tables to be restored.

- If a new restoration directory is selected to avoid affecting the current data, HDFS permission must be manually granted so that users who have permission of backup tables can access this directory.
- Data can be restored to other databases. In this case, HDFS permission must be manually granted so that users who have permission of backup tables can access the HDFS directory that corresponds to the database.

Step 10 Set **Force recovery** to **true**, which indicates to forcibly recover all backup data when a data table with the same name already exists. If the data table contains new data added after backup, the new data will be lost after the data recovery. If you set the parameter to **false**, the restoration task is not executed if a data table with the same name exists.

Step 11 Click **Verify** to check whether the restoration task is configured correctly.

- If the queue name is incorrect, the verification fails.
- If the specified directory to be restored does not exist, the verification fails.
- If the forcibly replacement conditions are not met, the verification fails.

Step 12 Click **OK**.

Step 13 In the restoration task list, locate a created task and click **Start** in the **Operation** column to execute the restoration task.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be executed again.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to execute the task again.

----End

10.11.3.15 Restoring IoTDB Metadata

Scenario

To ensure IoTDB metadata security and prevent the IoTDB service from being unavailable due to IoTDB file damage, IoTDB metadata needs to be backed up. In this way, the system can restore data timely when an exception is reported or an operation does not achieve the expected result, minimizing the impact on services.

System administrators can create an IoTDB restoration task on FusionInsight Manager. Only manual restoration tasks are supported.

NOTICE

- Data restoration can be performed only when the system version is consistent with that during data backup.
- To restore the data when services are normal, manually back up the latest management data first and then restore the data. Otherwise, the IoTDB data that is generated after the data backup and before the data restoration will be lost.
- You are advised to restore the metadata of only one component in a restoration task to prevent the stop of a service or instance from affecting the data restoration of other components. If data of multiple components is restored at the same time, data restoration may fail.

Impact on the System

After the metadata is restored, the data generated after the data backup and before the data restoration is lost.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the row where the specified backup task is located, choose **More** > **View History** in the **Operation** column to display the historical execution records of the backup task.

In the window that is displayed, select a success record and click **View** in the **Backup Path** column to view its backup path information and find the following information:

- **Backup Object**: indicates the backup data source.
- **Backup Path**: indicates the full path where backup files are stored.

  Select the correct path, and manually copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In **Restoration Configuration**, select **IoTDB** under **Metadata and other data**.

NOTE

If multiple IoTDB services are installed, select the IoTDB service to be restored.

Step 8 Select a backup directory type for **Path Type**.

The configurations vary based on backup directory types:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node.

  If you select this option, you also need to set **Source Path**, which indicates the backup file to be restored, for example, *Version_Data source_Task execution time*.**tar.gz**.

- **NFS**: indicates that backup files are stored in NAS using the NFS protocol.

  If you select this option, configure the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Source Path**: indicates the complete path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time*.**tar.gz**.

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select this option, configure the following parameters:

  - **Source NameService Name**: indicates the NameService name of the backup data cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Source Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster.
  - **Source Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster.
  - **Source NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the standby cluster.
  - **Source Path**: indicates the full path of HDFS directory for storing backup data of the standby cluster, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time*.**tar.gz**.

- **CIFS**: indicates that backup files are stored in NAS using the CIFS protocol.

  If you select this option, configure the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.

  - **Source Path**: indicates the complete path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time*.**tar.gz**.
- **SFTP**: indicates that backup files are stored in the server using the SFTP protocol.

  If you select this option, configure the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the server where the backup data is stored.
  - **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
  - **Username**: indicates the username for connecting to the server using the SFTP protocol.
  - **Password**: indicates the password for connecting to the server using the SFTP protocol.
  - **Source Path**: indicates the complete path of the backup file on the backup server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time*.**tar.gz**.

Step 9 Click **OK**.

Step 10 In the restoration task list, locate the row where the created task is located, and click **Start** in the **Operation** column.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be executed again.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to execute the task again.

Step 11 Choose **Cluster** > **Services** and start the IoTDB service.

----End

10.11.3.16 Restoring IoTDB Service Data

Scenario

IoTDB service data needs to be restored in the following scenarios: Data is modified or deleted unexpectedly and needs to be restored. After an administrator performs major operations (such as upgrade and data adjustment) on IoTDB, an exception occurs or the expected result is not achieved. All modules are faulty and become unavailable. Data is migrated to a new cluster.

System administrators can create an IoTDB restoration task on FusionInsight Manager. Only manual restoration tasks are supported.

NOTICE

- Data restoration can be performed only when the system version is consistent with that during data backup.
- To restore the data when services are normal, manually back up the latest management data first and then restore the data. Otherwise, the IoTDB data that is generated after the data backup and before the data restoration will be lost.

Impact on the System

- During data restoration, user authentication stops and users cannot create new connections.
- After the data is restored, the data generated after the data backup and before the data restoration is lost.
- After the data is restored, the IoTDB upper-layer applications need to be started.

Prerequisites

- If you need to restore data from a remote HDFS, prepare a standby cluster. If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust must be configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- The IoTDB backup file save path is correct.
- The IoTDB upper-layer applications are stopped.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the row where the specified backup task is located, choose **More** > **View History** in the **Operation** column to display the historical execution records of the backup task.

In the window that is displayed, select a success record and click **View** in the **Backup Path** column to view its backup path information and find the following information:

- **Backup Object**: indicates the backup data source.
- **Backup Path**: indicates the full path where backup files are stored.

  Select the correct path, and manually copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In **Restoration Configuration**, choose **IoTDB** > **IoTDB** under **Service Data**.

Step 8 Set **Path Type** of **IoTDB** to a backup directory type.

The following backup directory types are supported:

RemoteHDFS: indicates that the backup files are stored in the HDFS directory of the standby cluster.

If you select this option, configure the following parameters:

- **Source NameService Name**: indicates the NameService name of the backup data cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster.
- **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
- **Source Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster.
- **Source Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster.
- **Source NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the standby cluster.
- **Source Path**: indicates the full path of HDFS directory for storing backup data of the standby cluster, for example, *Backup path/Backup task name_Data source_Task creation time*.
- **Recovery Point List**: Click **Refresh** and select an IoTDB directory that has been backed up in the standby cluster.

Step 9 In the **Backup Data** column of the **Data Configuration** page, select one or more pieces of backup data that needs to be restored based on service requirements. In the **Target Path** column, specify the target location after backup data restoration.

You are advised to set **Target Path** to a new path that is different from the backup path.

Step 10 Set **Force recovery** to **true**, which indicates that all backup data is forcibly restored when a data table with the same name already exists. If the data table contains new data added after backup, the new data will be lost after the data restoration. If you set the parameter to **false**, the restoration task is not executed if a data table with the same name exists.

Step 11 Click **Verify** to check whether the restoration task is configured correctly.

- If the queue name is incorrect, the verification fails.
- If the specified directory to be restored does not exist, the verification fails.

Step 12 Click **OK**.

Step 13 In the restoration task list, locate the row where the created task is located, and click **Start** in the **Operation** column.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be executed again.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to execute the task again.

----End

10.11.3.17 Restoring Kafka Metadata

Scenario

Kafka data needs to be recovered in the following scenarios: data is modified or deleted unexpectedly and needs to be restored. After an administrator performs critical data adjustment in ZooKeeper, an exception occurs or the operation has not achieved the expected result. All Kafka modules are faulty and become unavailable. Data is migrated to a new cluster.

System administrators can create a recovery task in FusionInsight Manager to recover Kafka data. Only manual restoration tasks are supported.

NOTICE

- Data restoration can be performed only when the system version is consistent with that during data backup.
- To restore Kafka metadata when the service is running properly, you are advised to manually back up the latest Kafka metadata before restoration. Otherwise, the Kafka metadata that is generated after the data backup and before the data restoration will be lost.
- The content of this section is available for Kafka metadata restoration and not for service data restoration.

Impact on the System

- After the metadata is restored, the data generated after the data backup and before the data restoration is lost.
- After the metadata is restored, the offset information stored on ZooKeeper by Kafka consumers is rolled back, resulting in repeated consumption.

Prerequisites

- If you need to restore data from a remote HDFS, prepare a standby cluster. If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust has been configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters. For details, see **Enabling Cross-Cluster Replication**.

- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.
- The Kafka service is disabled first, and then enabled upon data restoration.
- You have logged in to FusionInsight Manager. For details, see **Logging In to FusionInsight Manager**.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the **Operation** column of a specified task in the task list, choose **More** > **View History** to view historical backup task execution records.

In the displayed window, locate a specified success record and click **View** in the **Backup Path** column to view the backup path information of the task and find the following information:

- **Backup Object** specifies the data source of the backup data.
- **Backup Path** specifies the full path where the backup files are saved.

  Select the correct item, and manually copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In the **Restoration Configuration** area, select **Kafka**.

NOTE

If multiple Kafka services are installed, select the Kafka services to be restored.

Step 8 Set **Path Type** of **Kafka** to a backup directory type.

The settings vary according to backup directory types:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node.

  If you select **LocalDir**, you also need to set **Source Path** to select the backup file to be restored, for example, *Version_Data source_Task execution time*.**tar.gz**.
- **LocalHDFS**: indicates that the backup files are stored in the HDFS directory of the current cluster.

  If you select **LocalHDFS**, set the following parameters:
  - **Source Path**: indicates the full path of the backup file in the HDFS, for example, *Backup path/Backup task name_Task creation time/Version_Data source_Task execution time*.**tar.gz**.
  - **Source NameService Name**: indicates the NameService name that corresponds to the backup directory when a restoration task is executed. The default value is **hacluster**.

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select **RemoteHDFS**, set the following parameters:

  - **Source NameService Name**: indicates the NameService name of the backup data cluster. You can enter the built-in NameService name of the remote cluster, for example, **haclusterX**, **haclusterX1**, **haclusterX2**, **haclusterX3**, or **haclusterX4**. You can also enter a configured NameService name of the remote cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Source NameNode IP Address**: indicates the NameNode service plane IP address of the standby cluster, supporting the active node or standby node.
  - **Source Path**: indicates the full path of HDFS directory for storing backup data of the standby cluster, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.
  - **Queue Name**: indicates the name of the Yarn queue used for backup task execution. The name must be the same as the name of the queue that is running properly in the cluster.

- **NFS**: indicates that backup files are stored in NAS using the NFS protocol.

  If you select **NFS**, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.

- **CIFS**: indicates that backup files are stored in NAS using the CIFS protocol.

  If you select **CIFS**, set the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Source Path**: indicates the full path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.

- **OBS**: indicates that backup files are stored in OBS.

  If you select **OBS**, set the following parameters:

- **Source Path**: indicates the full OBS path of a backup file, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time***.tar.gz**.

Step 9 Click **OK**.

Step 10 In the restoration task list, locate a created task and click **Start** in the **Operation** column to execute the restoration task.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be executed again.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to execute the task again.

NOTICE

- If the Kafka service is reinstalled and metadata is restored after data backup, or metadata is migrated to a new cluster, the Kafka broker cannot be started. View the error in the **/var/log/Bigdata/kafka/broker/server.log** file. An example is as follows:

```
ERROR Fatal error during KafkaServer startup. Prepare to shutdown (kafka.server.KafkaServer)kafka.common.InconsistentClusterIdException: The Cluster ID kVSgfurUQFGGpHMTBqBPiw doesn't match stored clusterId Some(0Qftv9yBTAmf2iDPSlIk7g) in meta.properties. The broker is trying to join the wrong cluster. Configured zookeeper.connect may be wrong. at kafka.server.KafkaServer.startup(KafkaServer.scala:220) at kafka.server.KafkaServerStartable.startup(KafkaServerStartable.scala:44) at kafka.Kafka$.main(Kafka.scala:84) at kafka.Kafka.main(Kafka.scala)
```

  Check the value of **log.dirs** in the Kafka Broker configuration file **${BIGDATA_HOME}/FusionInsight_Current/*Broker/etc/server.properties**. The value is the Kafka data directory. Go to the Kafka data directory and change the value **0Qftv9yBTAmf2iDPSlIk7g** of **cluster.id** in **meta.properties** to **kVSgfurUQFGGpHMTBqBPiw** (the latest value in the error log).
- The preceding modification must be performed on each node where Broker is located. After the modification, restart the Kafka service.

----End

10.11.3.18 Restoring Redis Data

Scenario

To ensure Redis data security or before and after a critical operation (such as upgrade and migration) on Redis, Redis data needs to be backed up. The backup data can be used to recover the system in time if an exception occurs or the expected result has not been achieved, minimizing the adverse impact on services.

System administrators can create a recovery task in FusionInsight Manager to recover Redis data. Only manual restoration tasks are supported.

NOTICE

Data restoration can be performed only when the system version is consistent with that during data backup.

Impact on the System

After the data is restored, the data generated after the data backup and before the data restoration is lost.

Prerequisites

- You have checked that HDFS services have been deployed in the current cluster.
- The name of the cluster created by Redis is the same as the cluster name in the backup task.
- You have logged in to FusionInsight Manager. For details, see **Logging In to FusionInsight Manager**.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the **Operation** column of a specified task in the task list, choose **More** > **View History** to view historical backup task execution records.

In the displayed window, locate a specified success record and click **View** in the **Backup Path** column to view the backup path information of the task and find the following information:

- **Backup Object** specifies the data source of the backup data.
- **Backup Path** specifies the full path where the backup files are saved.

  Select the correct item, and manually copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In the **Restoration Configuration** area, select **Redis**.

Step 8 Set **Path Type** of **Redis** to a backup directory type.

The settings vary according to backup directory types:

- **LocalHDFS**: indicates that the backup files are stored in the HDFS directory of the current cluster.

  If you select **LocalHDFS**, set the following parameters:

- **Source Path**: indicates the full path of the backup file in the HDFS. The specific path is the backup path set in **Step 2**.
- **Source NameService Name**: indicates the NameService name that corresponds to the backup directory when a restoration task is executed. The default value is **hacluster**.

Step 9 Click **OK**.

Step 10 In the restoration task list, locate a created task and click **Start** in the **Operation** column to execute the restoration task.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be executed again.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to execute the task again.

----End

10.11.3.19 Restoring RTDService Metadata

Scenario

Restore RTDService metadata in the following scenarios: Data is modified or deleted accidentally, or needs to be recovered; data exceptions occur or the change results are not as expected after major operations such as upgrade or data migration are performed on RTDService; all modules are faulty and become unavailable; data is migrated to a new cluster.

You can create a restoration task on FusionInsight Manager to restore RTDService metadata. Only manual restoration tasks are supported.

NOTICE

- Data can be restored only when the system version during data backup is the same as the current system version.
- To restore RTDService metadata when services are running properly, manually back up the latest RTDService metadata before restoration. Otherwise, the RTDService metadata generated after the data backup and before the data restoration will be lost.
- You are advised to restore the metadata of RTDService and Containers at the same time. If only the RTDService metadata is backed up and restored, RTDService needs to be brought offline and then online. If only the Containers metadata is backed up and restored, the service management status may be inconsistent with the running status.

Impact on the System

- After the metadata is restored, the data generated after the data backup and before the data restoration is lost.
- After the metadata is restored, the upper-layer applications of RTDService need to be restarted.

Prerequisites

- You have checked the path for storing RTDService metadata backup files.
- You have prepared a standby cluster if you need to restore data remotely from HDFS. If the active cluster is deployed in security mode (with Kerberos authentication enabled) and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust must be configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode (with Kerberos authentication disabled), mutual trust is not required.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the **Operation** column of the specified task in the task list, click **More** and select **View History**.

In the window that is displayed, select a success record and click **View** in the **Backup Path** column to view its backup path information and find the following information:

- **Backup Object**: indicates the backup data source.
- **Backup Path**: indicates the full path for storing backup files.

  Select the correct path and copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In **Restoration Configuration**, select **RTDService** under **Metadata and other data**.

Step 8 Set **Path Type** of **RTDService** to a restoration directory type.

The configurations vary based on backup directory types:

- **LocalDir**: indicates that data is restored from the local disk of the active management node.

  If you select this option, you also need to set **Source Path**, which indicates the backup file to be restored, for example, *Backup task name_Data source_Task execution time*.**tar.gz**.
- **LocalHDFS**: indicates that the backup files are stored in the HDFS directory of the current cluster.

  If you select this option, you also need to configure the following parameters:

  – **Source Path**: indicates the full path for storing backup files in HDFS, for example, *Backup path/Backup task name_Task creation time/Version_Data source_Task execution time*.**tar.gz**.

  - **Source NameService Name**: indicates the NameService name that corresponds to the backup directory when a restoration task is executed. The default value is **hacluster**.

- **RemoteHDFS**: indicates that data is restored from the HDFS directory of the standby cluster.

  If you select this option, you also need to configure the following parameters:

  - **Source NameService Name**: indicates the NameService name of the backup data cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects an IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Source Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster.
  - **Source Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster.
  - **Source NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the destination cluster.
  - **Source Path**: indicates the full path of HDFS directory for storing backup data of the standby cluster, for example, *Backup path/Backup task name_Data source_Task creation time/Data source_Task execution time*.**tar.gz**.

Step 9 Click **OK**.

Step 10 In the restoration task list, locate the row where the created task is, and click **Start** in the **Operation** column. In the dialog box that is displayed, click **OK** to start the restoration task.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be re-executed.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to re-execute the task.

----End

10.11.3.20 Restoring Solr Metadata

Scenario

Solr metadata needs to be restored in the following scenarios: Data is modified or deleted unexpectedly and needs to be restored. After an administrator performs major operations (such as upgrade and data adjustment) on ZooKeeper, an exception occurs or the expected result is not achieved. The Solr component is faulty and becomes unavailable. Data is migrated to a new cluster.

System administrators can create a Solr restoration task on FusionInsight Manager. Only manual restoration tasks are supported.

NOTICE

- Data restoration can be performed only when the system version is consistent with that during data backup.
- To restore Solr metadata when the service is running properly, you are advised to manually back up the latest Solr metadata before restoration. Otherwise, the Solr metadata that is generated after the data backup and before the data restoration will be lost.

Impact on the System

- Before restoring the metadata, you need to stop the Solr service. During this period, all upper-layer applications are affected and cannot work properly.
- After the metadata is restored, the data generated after the data backup and before the data restoration is lost.
- After the metadata is restored, the upper-layer applications of Solr need to be started.

Prerequisites

- If you need to restore data from a remote Solr, prepare a standby cluster. If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust must be configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.
- You have checked the path for storing Solr metadata backup files.
- The Solr service has been stopped before its metadata is restored.
- You have logged in to FusionInsight Manager. For details, see **Logging In to FusionInsight Manager**.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the row where the specified backup task is located, choose **More** > **View History** in the **Operation** column to display the historical execution records of the backup task.

In the window that is displayed, select a success record and click **View** in the **Backup Path** column to view its backup path information and find the following information:

- **Backup Object**: indicates the backup data source.
- **Backup Path**: indicates the full path where backup files are stored.

  Select the correct path, and manually copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In **Restoration Configuration**, select **Solr** under **Metadata and other data**.

NOTE

If multiple Solr services are installed, select the Solr service to be restored.

Step 8 Select a backup directory type for **Path Type**.

The configurations vary based on backup directory types:

- **LocalDir**: indicates that the backup files are stored on the local disk of the active management node.

  If you select this option, you also need to set **Source Path**, which indicates the backup file to be restored, for example, *Version_Data source_Task execution time*.**tar.gz**.

- **NFS**: indicates that backup files are stored in NAS using the NFS protocol.

  If you select this option, configure the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Source Path**: indicates the complete path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time*.**tar.gz**.

- **RemoteHDFS**: indicates that the backup files are stored in the HDFS directory of the standby cluster.

  If you select this option, configure the following parameters:

  - **Source NameService Name**: indicates the NameService name of the backup data cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster.
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Source Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster.
  - **Source Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster.
  - **Source NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the standby cluster.
  - **Source Path**: indicates the full path of HDFS directory for storing backup data of the standby cluster, for example, *Backup path/Backup task name_Data source_Task creation time*.

- **CIFS**: indicates that backup files are stored in NAS using the CIFS protocol.

  If you select this option, configure the following parameters:

  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the NAS server.
  - **Port**: indicates the port number used to connect to the NAS server over the CIFS protocol. The default value is **445**.
  - **Username**: indicates the username set when the CIFS protocol is configured.
  - **Password**: indicates the password set when the CIFS protocol is configured.
  - **Source Path**: indicates the complete path of the backup file on the NAS server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time*.**tar.gz**.
- **SFTP**: indicates that backup files are stored in the backup server using the SFTP protocol.

  If you select this option, configure the following parameters:
  - **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
  - **Server IP Address**: indicates the IP address of the server where the backup data is stored.
  - **Port**: indicates the port number used to connect to the backup server over the SFTP protocol. The default value is **22**.
  - **Username**: indicates the username for connecting to the server using the SFTP protocol.
  - **Password**: indicates the password for connecting to the server using the SFTP protocol.
  - **Source Path**: indicates the complete path of the backup file on the backup server, for example, *Backup path/Backup task name_Data source_Task creation time/Version_Data source_Task execution time*.**tar.gz**.

Step 9 Click **OK**.

Step 10 In the restoration task list, locate the row where the created task is located, and click **Start** in the **Operation** column.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be executed again.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to execute the task again.

Step 11 Log in to FusionInsight Manager and restart the Solr service.

----End

10.11.3.21 Restoring Solr Service Data

Scenario

Solr service data needs to be restored in the following scenarios: Data is modified or deleted unexpectedly and needs to be restored. After an administrator performs major operations (such as upgrade and data adjustment) on Solr, an exception occurs or the expected result is not achieved. All modules are faulty and become unavailable. Data is migrated to a new cluster.

System administrators can create a Solr service data restoration task on FusionInsight Manager. After the task is successfully executed, the service data is restored. Only manual restoration tasks are supported.

NOTICE

- Data restoration can be performed only when the system version is consistent with that during data backup.
- To restore Solr service data when services are normal, manually back up the latest service data first and then restore the data. Otherwise, the Solr service data that is generated after the data backup and before the data restoration will be lost.
- During the execution of a restoration task, if the index to be restored already exists, the index will be deleted and then automatically created. Therefore, index-related service operations may be affected during the restoration task execution.
- Ensure that the running status of all instances in the cluster is normal and can receive requests properly. To ensure successful restoration, do not perform operations such as adding, deleting, stopping, or restarting Solr instances, stopping or restarting the Solr service, or stopping or restarting the cluster.
- Solr metadata and service data cannot be restored at the same time. Otherwise, service data restoration fails.

Impact on the System

- After the data is restored, the data generated after the data backup and before the data restoration is lost.
- After the data is restored, the Solr upper-layer applications need to be started.

Prerequisites

- The Solr backup file save path is correct.
- The Solr upper-layer applications are stopped.
- If you need to restore data from a remote HDFS, prepare a standby cluster. If the active cluster is deployed in security mode and the active and standby clusters are not managed by the same FusionInsight Manager, mutual trust must be configured. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**. If the active cluster is deployed in normal mode, no mutual trust is required.

- Time is consistent between the active and standby clusters and the NTP services on the active and standby clusters use the same time source.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the **Operation** column of the specified task in the task list, choose **More** > **View History**.

In the window that is displayed, select a success record and click **View** in the **Backup Path** column to view its backup path information and find the following information:

- **Backup Object**: indicates the backup data source.
- **Backup Path**: indicates the full path where backup files are stored.

  Select the correct path, and manually copy the full path of backup files in **Backup Path**.

Step 3 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Restoration Management**.

Step 4 Click **Create**.

Step 5 Set **Task Name** to the name of the restoration task.

Step 6 Select the desired cluster from **Recovery Object**.

Step 7 In **Restoration Configuration**, choose **Solr** > **Solr** under **Service Data**.

Step 8 Set **Path Type** of **Solr** to a restoration directory type.

The following types of directories can be restored:

RemoteHDFS: indicates that the backup files are stored in the HDFS directory of the standby cluster.

If you select this option, configure the following parameters:

- **Source NameService Name**: indicates the NameService name of the backup data cluster, for example, **hacluster**. You can obtain it from the **NameService Management** page of HDFS of the standby cluster.
- **IP Mode**: indicates the mode of the target IP address. The system automatically selects the IP address mode based on the cluster network type, for example, **IPv4** or **IPv6**.
- **Source Active NameNode IP Address**: indicates the service plane IP address of the active NameNode in the standby cluster.
- **Source Standby NameNode IP Address**: indicates the service plane IP address of the standby NameNode in the standby cluster.
- **Source NameNode RPC Port**: indicates the value of **dfs.namenode.rpc.port** in the HDFS basic configuration of the standby cluster.
- **Source Path**: indicates the full path of HDFS directory for storing backup data of the standby cluster, for example, *Backup path/Backup task name_Data source_Task creation time*.

- **Recovery Point List**: Click **Refresh** and select a Solr snapshot directory that has been backed up in the standby cluster.

Step 9 In the **Data Configuration** area, select one or more indexes for **Backup Object** based on service requirements.

Step 10 Specify **Force recovery**. The value **false** does not take effect. All backup data is forcibly restored when there are indexes with the same name. If the index contains data added after backup, the added data will be lost after the data restoration.

Step 11 Click **Verify** to check whether the restoration task is configured correctly.

- If the specified directory to be restored does not exist, the verification fails.
- If the forcible restoration conditions are not met, the verification fails.

Step 12 Click **OK**.

Step 13 In the restoration task list, locate the row where the created task is located, and click **Start** in the **Operation** column.

- After the restoration is successful, the progress bar is in green.
- After the restoration is successful, the restoration task cannot be executed again.
- If the restoration task fails during the first execution, rectify the fault and click **Retry** to execute the task again.

----End

10.11.4 Enabling Cross-Cluster Replication

Scenario

DistCp is used to replicate the data stored in HDFS from a cluster to another cluster. DistCp depends on the cross-cluster replication function, which is disabled by default. You need to enable it for both clusters.

This section describes how to modify parameters on FusionInsight Manager to enable the cross-cluster replication function. After this function is enabled, you can create a backup task for backing up data to the remote HDFS (RemoteHDFS).

Impact on the System

Yarn needs to be restarted to enable the cross-cluster replication function and cannot be accessed during restart.

Prerequisites

- The **hadoop.rpc.protection** parameter of HDFS in the two clusters for data replication must use the same data transmission mode. The default value is **privacy**, indicating encrypted transmission. The value **authentication** indicates that transmission is not encrypted.
- For clusters in security mode, you need to configure mutual trust between clusters.

Procedure

Step 1 Log in to FusionInsight Manager of one of the two clusters.

Step 2 Choose **Cluster** > **Services** > **Yarn** and click **Configurations** then **All Configurations**.

Step 3 In the navigation pane, choose **Yarn(Service)** > **Distcp**.

Step 4 Modify **dfs.namenode.rpc-address**, set **haclusterX.remotenn1** to the service IP address and RPC port of one NameNode instance of the peer cluster, and set **haclusterX.remotenn2** to the service IP address and RPC port number of the other NameNode instance of the peer cluster.

haclusterX.remotenn1 and **haclusterX.remotenn2** do not distinguish active and standby NameNodes. The default NameNode RPC port is 8020 and cannot be modified on Manager.

Examples of modified parameter values: **10.1.1.1:8020** and **10.1.1.2:8020**.

NOTE

- If data of the current cluster needs to be backed up to the HDFS of multiple clusters, you can configure the corresponding NameNode RPC addresses to haclusterX1, haclusterX2, haclusterX3, and haclusterX4.

Step 5 Click **Save**. In the confirmation dialog box, click **OK**.

Step 6 Restart the Yarn service.

Step 7 Log in to FusionInsight Manager of the other cluster and repeat **Step 2** to **Step 6**.

----End

10.11.5 Managing Local Quick Restoration Tasks

Scenario

When DistCp is used to back up data, the backup snapshot is saved to HDFS of the active cluster. FusionInsight Manager supports using the local snapshot for quick data restoration, requiring less time than restoring data from the standby cluster.

Use FusionInsight Manager and the snapshots on HDFS of the active cluster to create a local quick restoration task and execute the task.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the backup task list, locate a created task and click **Restore** in the **Operation** column.

Step 3 Check whether the system displays "No data is available for quick restoration. Create a task on the restoration management page to restore data".

- If yes, click **OK** to close the dialog box. No backup data snapshot is created in the active cluster, and no further action is required.

- If no, go to **Step 4** to create a local quick restoration task.

NOTE

Metadata does not support quick restoration.

Step 4 Set **Name** to the name of the local quick restoration task.

Step 5 Set **Configuration** to a data source.

Step 6 Set **Recovery Point List** to a recovery point that contains the backup data.

Step 7 Set **Queue Name** to the name of the Yarn queue used in the task execution. The name must be the same as the name of the queue that is running properly in the cluster.

Step 8 Set **Data Configuration** to the object to be recovered.

Step 9 Click **Verify**, and wait for the system to display "The restoration task configuration is verified successfully."

Step 10 Click **OK**.

Step 11 In the restoration task list, locate a created task and click **Start** in the **Operation** column to execute the restoration task.

After the task is complete, **Task Status** of the task is displayed as **Successful**.

----End

10.11.6 Modifying a Backup Task

Scenario

This section describes how to modify the parameters of a created backup task on FusionInsight Manager to meet changing service requirements. The parameters of restoration tasks can only be viewed but cannot be modified.

Impact on the System

After a backup task is modified, the new parameters take effect when the task is executed next time.

Prerequisites

- A backup task has been created.
- A new backup task policy has been planned based on the actual situation.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration** > **Backup Management**.

Step 2 In the task list, locate a specified task, click **Configure** in the **Operation** column to go to the configuration modification page.

On the displayed page, modify the following parameters:

- Started
- Period
- Destination NameService Name
- Target NameNode IP Address
- Target Path
- Max Number of Backup Copies
- Maximum Number of Recovery Points
- Maximum Number of Maps
- Maximum Bandwidth of a Map

NOTE

After the **Target Path** parameter of a backup task is modified, this task will be performed as a full backup task for the first time by default.

Step 3 Click **OK** to save the settings.

----End

10.11.7 Viewing Backup and Restoration Tasks

Scenario

This section describes how to view created backup and recovery tasks and check their running status on FusionInsight Manager.

Prerequisites

You have logged in to FusionInsight Manager. For details, see **Logging In to FusionInsight Manager**.

Procedure

Step 1 On FusionInsight Manager, choose **O&M** > **Backup and Restoration**.

Step 2 Click **Backup Management** or **Restoration Management**.

Step 3 In the task list, obtain the previous execution result in the **Task Status** and **Task Progress** column. Green indicates that the task is executed successfully, and red indicates that the execution fails.

Step 4 In the **Operation** column of a specified task in the task list, choose **More** > **View History** or click **View History** to view the historical record of backup and restoration task execution.

In the displayed window, click ⌄ before a specified record to display log information about the execution.

----End

Related Tasks

- Starting a backup or restoration task

In the task list, locate a specified task and choose **More** > **Back Up Now** or click **Start** in the **Operation** column to start a backup or restoration task that is ready or fails to be executed. Executed restoration tasks cannot be repeatedly executed.

- Stopping a backup or restoration task

  In the task list, locate a specified task and choose **More** > **Stop** or click **Stop** in the **Operation** column to stop a backup or restoration task that is running. After the task is successfully stopped, its **Task Status** changes to **Stopped**.

- Deleting a backup or restoration task

  In the task list, locate a specified task and choose **More** > **Delete** or click **Delete** in the **Operation** column to delete a backup or restoration task. Backup data will be reserved by default after a task is deleted.

- Suspending a backup task

  In the task list, locate a specified task and choose **More** > **Suspend** in the **Operation** column to suspend a backup task. Only periodic backup tasks can be suspended. Suspended backup tasks are no longer executed automatically. When you suspend a backup task that is being executed, the task execution stops. To resume a task, choose **More** > **Resume**.

10.12 SQL Inspector

10.12.1 Overview

SQL engines in the big data field are emerging one after another. In addition to a wide range of solutions, some problems are exposed. For example, the quality of SQL input statements is uneven, SQL problems are difficult to locate, and large SQL statements consume too many resources.

Low-quality SQL statements pose unexpected impacts on the data analysis platform, degrading system performance or platform stability.

Function Description

MRS allows you to configure inspection rules for mainstream SQL engines (Hive, Spark, HetuEngine, and ClickHouse). MRS can identify typical large SQL queries and low-quality SQL statements and intercepts them before execution or block them during execution. Users do not need to change how they submit SQL statements or change SQL syntax. Service modifications are not required and inspection is easy to implement.

- You can configure SQL inspection rules on the UI that also allows you to query and modify the rules.
- During query response and execution, each SQL engine proactively inspects SQL statements based on the rules.
- Administrators can select to display hints on, intercept, or block SQL statements. The system logs SQL inspection events in real time for SQL audit. O&M engineers can analyze the logs, evaluate SQL statement quality on the live network, detect target statements, and take effective measures.

SQL inspection rules are classified into the following types:

- Static interception: The system displays hints on or intercepts SQL statements based on SQL syntax rules.
- Dynamic interception: The system displays hints on or intercepts SQL statements based on rules of data table statistics and metadata information.
- Runtime Blocking: The system blocks SQL statements based on system states (such as CPU, memory, and I/O) during the runtime of the SQL statements.

SQL requests that meet the static and dynamic interception rules can be intercepted, and the system gives hints for processing the statements properly. If a SQL request meets the blocking rule, the system blocks the SQL task.

Rules and Restrictions

- A SQL inspection rule can be associated with multiple SQL engines, and different threshold parameters can be configured for each service.
- A SQL inspection rule can be associated with multiple tenants. A rule takes effect only for associated tenants.

10.12.2 Adding an SQL Inspection

Scenario

You can add rules for specified tenants and SQL engines on FusionInsight Manager. The system will display hints on, intercept, or block SQL requests matched by the rules.

NOTE

Exercise caution when you add or modify a SQL inspection rule for a cluster, enable a rule, and set the threshold. An improper rule may cause upper-layer service interruption.

Adding a Rule

Step 1 Log in to FusionInsight Manager as a user with the Manager administrator rights.

Step 2 Click **Cluster** and choose **SQL Inspector**. The **SQL Inspector** page is displayed.

You can click **View Supported Rules** to view all SQL inspection rules supported by the current cluster.

Step 3 Click **Add Rule**. After the password of the current user is verified, the **Add Rule** page is displayed.

Step 4 Set the required parameters and click **OK**.

Parameter	Description
Name	Name of a SQL inspection rule
ID	Rule ID For details about meaning of the rules corresponding to the IDs, see **Table 10-96**.

Parameter	Description
Tenant	Click **Add** to select the name of the tenant to which the current rule will be associated. If you need to add a new tenant, plan and create a cluster tenant by referring to **Tenant Resources**.
Services and Actions	Click **Add** to specify the SQL engine to which this rule will be associated with and set the threshold parameters of the rule. Each rule can be associated with one SQL engine. If you want to configure a rule for other SQL engines, add new rules. • **Service**: Select the SQL engine associated with the current rule. • If an SQL request meets the rule, the system performs the following operations: – **Hint**: Record logs and display a hint for handling the SQL request. If the rule has parameters, you need to configure the threshold. – **Intercept**: Intercept the SQL request that meets the rule. If the rule has parameters, you need to configure the threshold. – **Block**: Block the SQL request that meets the rule. If the rule has parameters, you need to configure the threshold. **NOTE** For static and dynamic interception rules, **Hint** and **Block** operations are supported. For blocking rules, only the **Block** operation is supported.

Step 5 View the added prevention rule on the **SQL Defense** page. The rule takes effect dynamically.

To adjust the current rule, click **Modify** in the **Operation** column of the row that contains the target rule. After the user password is verified, you can modify rule parameters.

Figure 10-18 Viewing SQL inspection rules

----End

MRS SQL Inspection Rules

Table 10-96 MRS SQL inspection rules

ID	Description	Engine	Threshold	Example SQL Statement
static_0001	Check whether the number of occurrences of count(distinct) in the SQL statement exceeds the limit.	• Hive • Spark • HetuEngine	Number of occurrences of count(distinct) Recommended value: **10**	SELECT COUNT(DISTINCT deviceId), COUNT(DISTINCT collDeviceId) FROM table GROUP BY deviceName, collDeviceName, collCurrentVersion;
static_0002	Check whether the not in <subquery> statement is used in the SQL statement.	• Hive • Spark • HetuEngine	N/A	SELECT * FROM Orders o WHERE Orders.Order_ID not in (Select Order_ID FROM HeldOrders h where h.order_id = o.order_id);
static_0003	Check whether the number of joins in the SQL statement exceeds the limit.	• Hive • Spark • HetuEngine	Number of joins Recommended value: **20**	N/A

ID	Description	Engine	Threshold	Example SQL Statement
static_0004	Check whether the number of union all times in the SQL statement exceeds the limit.	• Hive • Spark • HetuEngine	Number of union all times Recommended value: **20**	select * from tables t1 union all select * from tables t2 union all select * from tables t3 union all select * from tables t4 union all select * from tables t5 union all select * from tables t6 union all select * from tables t7 union all select * from tables t8 union all select * from tables t9;
static_0005	The number of subquery nesting layers exceeds the limit.	• Hive • Spark • HetuEngine	Maximum number of nested subqueries Recommended value: **20**	select * from (with temp1 as (select * from tables) select * from temp1);
static_0006	Check whether the length of the SQL statement string exceeds the upper limit.	• Hive • Spark • HetuEngine	Length of the SQL string, in KB Recommended value: **10**	N/A
static_0007	Check whether the Cartesian product exists when multiple tables are associated.	• Hive • Spark • HetuEngine	N/A	select * from A,B;
static_0008	Check whether alter table update operation is performed at the cluster level (on cluster).	ClickHouse	N/A	alter table testtb1 on cluster default_cluster update price=10.0 where id='100'

ID	Description	Engine	Threshold	Example SQL Statement
static_0009	Check whether alter table delete operation is performed at the cluster level (on cluster).	ClickHouse	N/A	alter table testtb1 on cluster default_cluster delete where id ='10'
static_0010	Check whether the alter table add column operation is performed at the cluster level (on cluster).	ClickHouse	N/A	alter table testtb1 on cluster default_cluster add column testc String
static_0011	Check whether the alter table drop column operation is performed at the cluster level (on cluster).	ClickHouse	N/A	alter table testtb1 on cluster default_cluster drop column testc
static_0012	Check whether the optimize final operation is performed at the cluster level (on cluster).	ClickHouse	N/A	optimize table testtb1 on cluster default_cluster final
static_0013	Check whether drop operations are performed at the cluster level (on cluster).	ClickHouse	N/A	drop table/ database test on cluster default_cluster;
static_0014	Check whether the truncate table operation is performed at the cluster level (on cluster).	ClickHouse	N/A	truncate table testtb1 on cluster default_cluster;
dynamic_0001	Check whether the number of scanned files exceeds the limit.	• Hive • Spark • HetuEngine	Number of files that will be scanned or have been scanned Recommended value: **100,000**	SELECT ss_ticket_number FROM store_sales WHERE ss_ticket_number= 72291252 LIMIT 10;

ID	Description	Engine	Threshold	Example SQL Statement
dynamic_0002	Check whether the number of partitions involved in operations (select, delete, update, and alter) on a table exceeds the upper limit.	• Hive • Spark • HetuEngine • ClickHouse	Number of partitions involved in the delete or alter operation Recommended value: **10,000**	DELETE FROM table_name WHERE column_name = value
dynamic_0003	When the right table of a join is a distributed table, check whether the data volume of the right table exceeds the upper limit.	ClickHouse	Number of rows in the right table when the join operation is performed. Recommended value: **100,000,000**	SELECT name, text FROM table_1 JOIN table_2 ON table_1.Id = table_2.Id
running_0001	Check whether the number of result rows returned by the Select statement to the client exceeds the upper limit.	• Hive • Spark • HetuEngine • ClickHouse	Number of rows in the query result Recommended value: **100,000**	select * from table
running_0002	Check whether the peak memory usage of the SQL statement exceeds the absolute value limit.	• Hive • Spark • HetuEngine • ClickHouse	Memory occupied by SQL running, in MB	N/A
running_0003	Check whether the running duration of the SQL statement exceeds the upper limit.	• Hive • Spark • HetuEngine • ClickHouse	SQL running duration threshold, in seconds	N/A

ID	Description	Engine	Threshold	Example SQL Statement
running_0004	The amount of data scanned by the SQL statements.	• Hive • Spark • HetuEngine • ClickHouse	Amount of data scanned by the SQL statement, in GB Recommended value: **10,240**	N/A

10.12.3 Configuring Hive SQL Inspection

Scenario

You can configure rules for Hive SQL inspection on FusionInsight Manager and configure rule parameters as you need.

Prerequisites

- The cluster client that contains the Hive service has been installed in the **/opt/hadoopclient** directory.
- The Hive service of the cluster is running properly.
- For a cluster with Kerberos authentication enabled, a user with Hive operation permissions has been created.

Constraints

- By default, SQL inspection rules need 5 seconds to take effect dynamically. After the queue is modified, it takes 10 minutes for Hive inspection rules to be reloaded.
- Interception and blocking rules will interrupt SQL tasks, so you need to set parameters of these rules properly based on the site requirements.
- For the rule dynamic_0001 (the number of files scanned by SQL statements exceeds the threshold), when the Spark and Tez engines reach the threshold, interception logs are printed in Yarn task logs and cannot be output on the Beeline client.
- Blocking rules have execution latency. For example, if the running_0004 rule is used and the threshold of the scanned data volume is 10 GB, the statement may be blocked when the data volume is 15 GB or higher due to the determination period and task concurrency.

Procedure

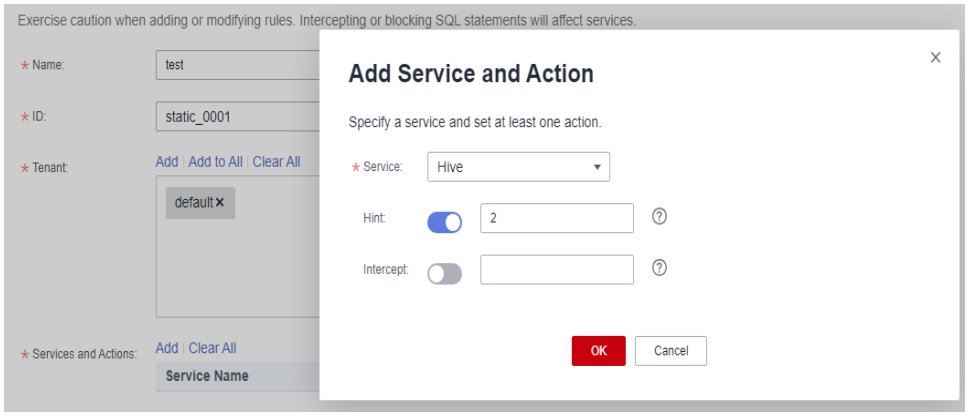
Step 1 Log in to FusionInsight Manager, click **Cluster**, and choose **SQL Inspector**. The **SQL Inspector** page is displayed.

Step 2 Add rules for Hive by referring to **Adding an SQL Inspection**.

For details about the rules supported by the Hive SQL engine, see **MRS SQL Inspection Rules**.

For example, add a rule whose ID is **static_0001** to check whether count distinct appears more than two times in the SQL statement. If so, the system displays a hint.

Figure 10-19 Adding a Hive SQL inspection rule



Step 3 Log in to the node where the Hive client is installed and run the following command to switch to the client installation directory.

cd /opt/hadoopclient

Run the following command to set environment variables:

source bigdata_env

Run the following command to authenticate the current user. Skip this step if Kerberos authentication is disabled for the cluster (the cluster is in normal mode).

kinit *Component service user who has the Hive operation permission*

Step 4 Run the following command to log in to the Hive client:

beeline

Step 5 Run the following commands to create a table and import data to the table.

drop table if exists hivetb;

create table hivetb(a int,b int);

insert into hivetb select 1,11;

insert into hivetb select 2,22;

Step 6 Run the following SQL statement to check whether the current rule takes effect:

select count(distinct a),count(distinct b) from hivetb;

If the number of times count distinct appears in the statement exceeds the threshold configured in **Step 2**, the following information is displayed:

```
...
WARN  : STATIC_0001 The count(distinct X) times exceeds the limit : 2, current count distinct times : 2
...
```

If the operation set in the rule is **Block**, the statement fails to be executed and the following information is displayed:

```
...
Error: Error while compiling statement: FAILED: RuleException STATIC_0001 The count(distinct X) times exceeds the limit : 2, current count distinct times : 2 (state=42000,code=40000)
...
```

NOTE

- For more Hive SQL inspection rules, see **MRS SQL Inspection Rules**.
- You can also obtain the SQL inspection rules via logs which are stored in **/var/log/Bigdata/audit/hive/hiveserver/queryinfo.log**.

----End

10.12.4 Configuring ClickHouse SQL Inspection

Scenario

You can configure rules for ClickHouse SQL inspection on FusionInsight Manager and configure rule parameters as you need.

Prerequisites

- The cluster client that contains the ClickHouse service has been installed in the **/opt/hadoopclient** directory.
- The ClickHouse logical cluster is running properly.
- For clusters with Kerberos authentication enabled, a service user who has the permission to operate ClickHouse tables has been created, for example, a human-machine user **clickhouseuser**.
- A tenant associated with the ClickHouse service has been created and associated with the ClickHouse service user.

Constraints

- The default dynamic validity period of a rule is 1 minute.
- Interception and blocking rules will interrupt SQL queries, so you need to set parameters of these rules properly based on the site requirements.
- After configuring ClickHouse rules, you need to log in to the client again for the rules to take effect.

Procedure

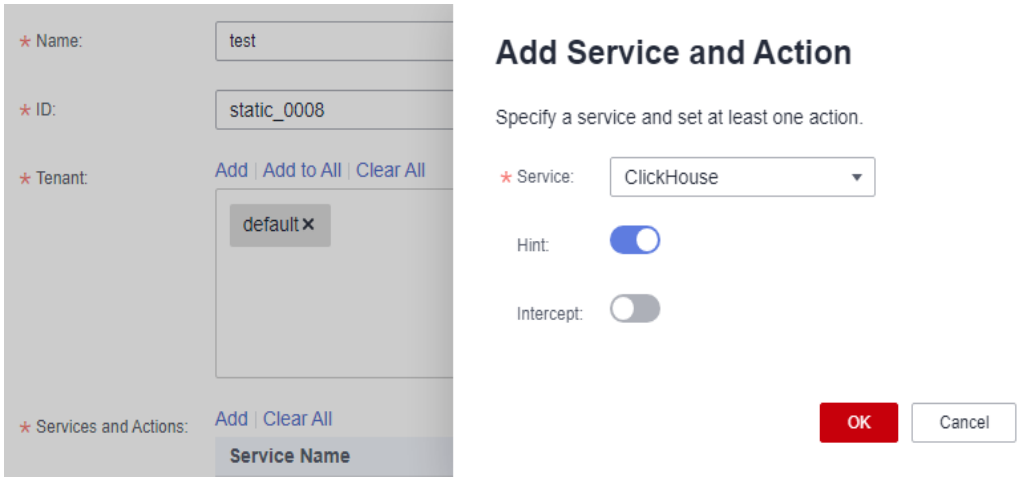
Step 1 Log in to FusionInsight Manager, click **Cluster**, and choose **SQL Inspector**. The **SQL Inspector** page is displayed.

Step 2 Add rules for ClickHouse by referring to **Adding an SQL Inspection**.

For details about the rules supported by the ClickHouse SQL engine, see **MRS SQL Inspection Rules**.

For example, add a rule whose ID is **static_0008** and checks whether a SQL statement executes the cluster-level table update operation. If so, the system displays a hint.

Figure 10-20 Adding a ClickHouse SQL inspection rule



Step 3 Log in to the node where the ClickHouse client is installed and run the following command to switch to the client installation directory.

cd /opt/hadoopclient

Run the following command to set environment variables:

source bigdata_env

Step 4 If the current cluster is in security mode (Kerberos authentication is enabled), run the following command to authenticate the current user. The current user must have the permission to create ClickHouse tables. If the current cluster is in normal mode (Kerberos authentication is disabled), skip this step.

kinit *Component service user*

Example: **kinit clickhouseuser**

Step 5 Use the ClickHouse client to connect to the ClickHouse server.

Security mode

clickhouse client --host *IP address of the ClickHouseServer instance* **--port 9440 --secure**

Normal clusters:

clickhouse client --host *IP address of the ClickHouseServer instance*--**user** *Username* **--password --port 9000**

Enter the password.

Step 6 Run the following statements to create a data table:

CREATE DATABASE *cktest* **ON CLUSTER** *default_cluster*;

CREATE TABLE *cktest.test2* **ON CLUSTER** *default_cluster* **(`EventDate` DateTime, `CounterID` UInt32, `UserID` UInt32, `ver` UInt16) ENGINE = ReplicatedMergeTree('/clickhouse/tables/{shard}/***cktest/test2***', '{replica}') PARTITION BY toYYYYMM(EventDate) ORDER BY (EventDate, intHash32(UserID));**

CREATE TABLE *cktest.test2_dir* **ON CLUSTER** *default_cluster* **as** *cktest.test2* **ENGINE = Distributed(***default_cluster, cktest, test2***, rand());**

Step 7 Run the following command to insert data to the table:

insert into *cktest.test2* **values('2023-08-01',111,111,111);**

insert into *cktest.test2* **values('2023-08-02',222,111,111);**

Step 8 Run the following SQL statement for the created table to check whether the rule takes effect:

alter table *cktest.test2* **on cluster** *default_cluster* **update CounterID = toUInt32(222) where EventDate='2023-08-01' ;**

```
...
<Warning> SQLDefender: Distributed DDL ALTER UPDATE queries are undesirable.
...
```

If the operation set in the rule is **Intercept**, the statement fails to be executed and the following information is displayed:

```
...
DB::Exception: Distributed DDL ALTER TABLE UPDATE queries are undesirable..(QUERY_IS_PROHIBITED)
...
```

NOTE

For more ClickHouse SQL inspection rules, see **MRS SQL Inspection Rules**.

----End

10.12.5 Configuring HetuEngine SQL Inspection

Scenario

You can configure rules for HetuEngine SQL inspection on FusionInsight Manager and configure rule parameters as you need.

Prerequisites

- The cluster client that contains the HetuEngine service has been installed in the **/opt/hadoopclient** directory.
- The HetuEngine service and compute instances are running properly.
- For clusters with Kerberos authentication enabled, a HetuEngine user has been created and granted related permissions. In addition, the user has been granted by Ranger the permission to manage databases, tables, and columns of the data source..

Constraints

- The default dynamic validity period of a rule is 5 minutes.
- Interception and blocking rules will interrupt SQL queries, so you need to set parameters of these rules properly based on the site requirements.
- Blocking rules are controlled by session-level parameters of the system. To configure blocking rules, service users must have the set session permission.
- For static rule **static_0003**, the total number of joins in queries does not include Semi joins and Anti joins.

- When prompt rules are configured for dynamic_0001 and dynamic_0002, prompt messages are recorded only in logs and are not displayed on the client.
- The client and server send asynchronous requests. For blocking rule **Running_0001**, after the server blocks the requests, the message "Query is gone " may be displayed on the client. In this case, you can view logs to check whether the requests are blocked.

Procedure

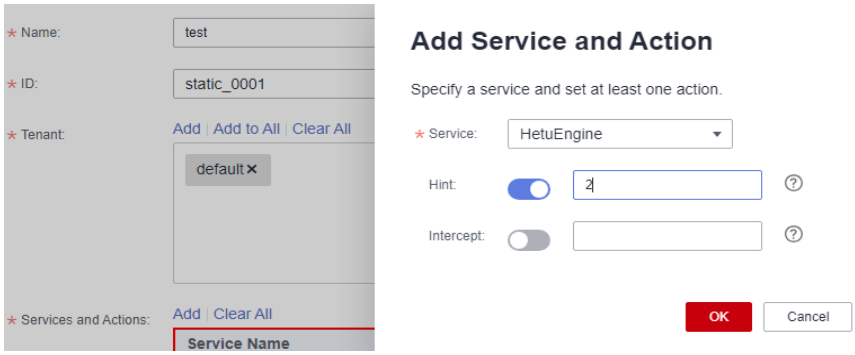
Step 1 Log in to FusionInsight Manager, click **Cluster**, and choose **SQL Inspector**. The **SQL Inspector** page is displayed.

Step 2 Add rules for HetuEngine by referring to **Adding an SQL Inspection**.

For details about the rules supported by the HetuEngine SQL engine, see **MRS SQL Inspection Rules**.

For example, add a rule whose ID is **static_0001** to check whether count distinct appears more than two times in the SQL statement. If so, the system displays a hint.

Figure 10-21 Adding a HetuEngine SQL inspection rule



Step 3 Log in to the node where the HetuEngine client is installed and run the following command to switch to the client installation directory:

cd /opt/hadoopclient

Run the following command to set environment variables:

source bigdata_env

Step 4 Log in to the HetuEngine client based on the cluster authentication mode.

- In security mode, run the following command to authenticate the user and log in to the HetuEngine client:

  kinit hetu_test

  hetu-cli --catalog hive --tenant default --schema default

- In normal mode, run the following command to log in to the HetuEngine client:

  hetu-cli --catalog hive --tenant default --schema default --user hetu_test

NOTE

hetu_test is a service user who has at least the tenant role specified by **--tenant** and cannot be an OS user.

Step 5 Check whether the current rule takes effect.

Run the following statement to create a table:

CREATE TABLE table1(id int, name varchar,rank int);

INSERT INTO table1 VALUES(10,'sachin',1),(45,'rohit',2),(46,'rohit',3),(18,'virat',4),(25,'dhawan',5);

Run the following statement to query data:

select count(distinct id),count(distinct id),count(distinct id),count(distinct id),count(distinct id),count(distinct id) from table1;

If the number of times count distinct appears in the statement exceeds the threshold configured in **Step 2**, the following information is displayed:

```
WARNING: Occurrence number of 'COUNT(DISTINCT XX)' (6) reaches the hint limitation (2)
```

NOTE

- If the action set in the rule is **Intercept** or **Block**, the following information may be displayed:
  ```
  Intercepted. Reason: Occurrence number of 'COUNT(DISTINCT XX)' (6) reaches the interception limitation (2)
  ```
- You can query HetuEngine SQL inspection details in logs stored in **hdfs://hacluster/hetuserverhistory/tenant/coordinator/application_ID/container_ID/yyyyMMdd/server.log**.
- If warning information is required for JDBC secondary development, add the following configuration for the JDBC application:
  ```
  statement = connection.prepareStatement(sql.trim());
  resultSet = statement.executeQuery();
  SQLWarning sqlWarning = statement.getWarnings();
  ```

----End

10.12.6 Configuring Spark SQL Inspection

Scenario

You can configure rules for Spark SQL inspection on FusionInsight Manager and configure rule parameters as you need.

Prerequisites

- The cluster client that contains the Spark service has been installed in the **/opt/hadoopclient** directory.
- Spark is running properly.
- A tenant, for example, **sparkstatic1** has been added to **Tenant Resources**.
- For a cluster with Kerberos authentication enabled, a service user has been created, for example, user **sparkuser**. The user belongs to groups **hive**, **hadoop**, and **supergroup**, the primary group is **hive**, and the bound role is set to **sparkstatic1**.

Constraints

- The default dynamic validity period of a rule is 6 minutes.
- Only SQL jobs are supported.
- Interception and blocking rules will interrupt SQL queries, so you need to set parameters of these rules properly based on the site requirements.
- The static rule static_0007 is not required for Spark because it has a Cartesian product restriction (controlled by **spark.sql.crossJoin.enabled**, which is **true** by default). If the spark parameter is **false**, the static_0007 rule will not take effect.
- Dynamic rules do work on carbon tables.
- The dynamic rule dynamic_0002 supports SELECT, ALTER TABLE ADD PARTITION and ALTER TABLE DROP PARTITION. If you use a batch deletion statement that contains judgment conditions, for example, ALTER TABLE DROP PARTITION (pt < 10), the statement will be intercepted before the dynamic_0002 rule because the number of partitions is limited by **spark.sql.dropPartitionsInBatch.limit**, which is defaulted to **1000**.
- Blocking rules has execution latency. For example, if the running_0004 rule is used and the threshold of the scanned data volume is 10 GB, the statement may be blocked when the data volume is 15 GB or higher due to the determination period and task concurrency.
- If a job does not exceed the threshold until the last several tasks are complete before the block action is triggered, the job cannot be canceled.
- Blocking rule running_0004: The SQL execution duration includes the execution duration on the Driver side and the job running duration. When the SQL execution is blocked on the Driver side, the job cannot be canceled even if the execution duration exceeds the value of interruption threshold. This problem may occur when INSERT OVERWRITE is performed on a large number of partitions where storage and compute are decoupled.

Procedure

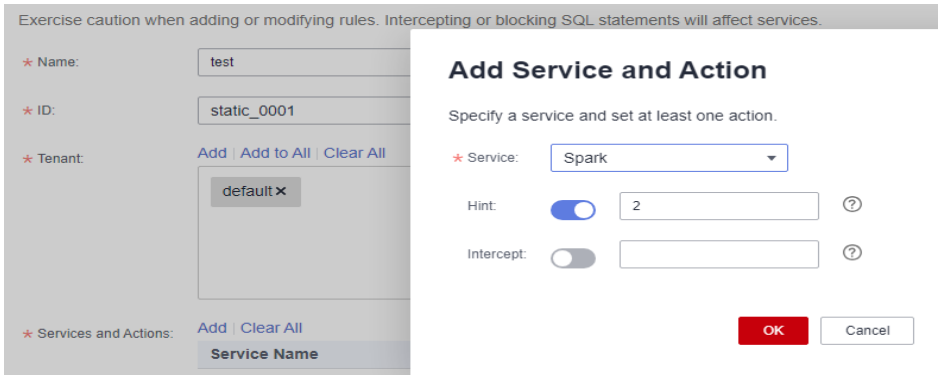
Step 1 Log in to FusionInsight Manager, click **Cluster**, and choose **SQL Inspector**. The **SQL Inspector** page is displayed.

Step 2 Add rules for Spark by referring to **Adding an SQL Inspection**.

For details about the rules supported by the Spark SQL engine, see **MRS SQL Inspection Rules**.

For example, add a rule whose ID is **static_0001** to check whether count distinct appears more than two times in the SQL statement. If so, the system displays a hint.

Figure 10-22 Adding a Spark SQL inspection rule



Step 3 Log in to the node where the Spark client is installed and run the following command to switch to the client installation directory.

cd /opt/hadoopclient

Run the following command to set environment variables:

source bigdata_env

source Spark/component_env

Step 4 Perform user authentication for clusters in security mode (Kerberos authentication enabled). Skip this step for clusters in normal mode (Kerberos authentication disabled).

kinit *Spark operation user*

Example:

kinit sparkuser

Enter the password as prompted and change the password upon your first login.

Step 5 Run the following command to log in to the spark-sql client:

cd opt/client/Spark/spark/bin

./spark-sql

Step 6 Run the following SQL statement on the client to check whether the current rule takes effect:

Run the following statement to create a table:

create table table1(id int, name string) stored as parquet

Run the following statement to query data:

select count(distinct id),count(distinct id),count(distinct id),count(distinct id),count(distinct id),count(distinct id) from table1;

If the number of times count distinct appears in the statement exceeds the threshold configured in **Step 2**, the following information is displayed:

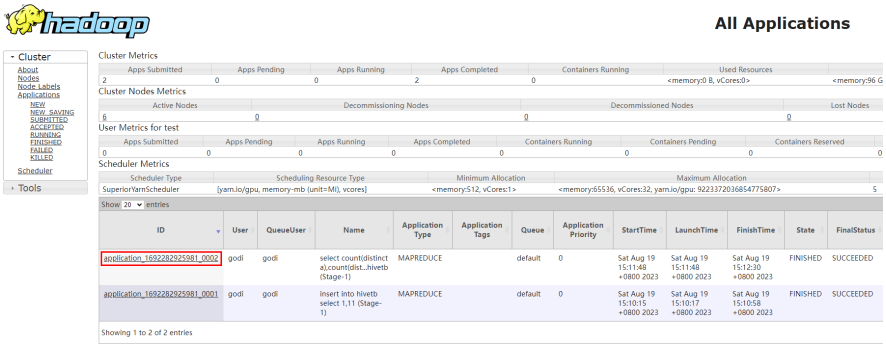
```
WARNING:  static_0001 Occurrence num of 'COUNT(DISTINCT)'(6) reaches the hint threshold(2)
```

If the action set in the rule is **Intercept**, the following information is displayed:

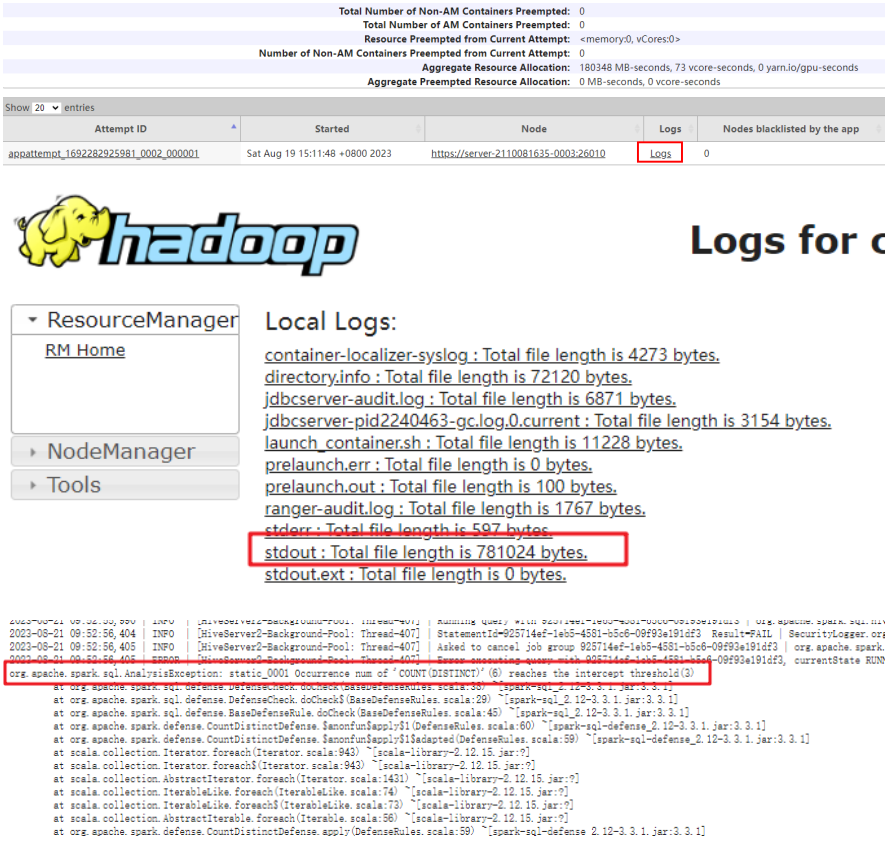
```
Error in query: static_0001 Occurrence num of 'COUNT(DISTINCT)'(6) reaches the intercept threshold(2)
```

In Spark Beeline, you can obtain SQL inspection details from logs.

1. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Yarn**. On the **Dashboard** page, click the link next to **ResourceManager WebUI** to enter the Yarn web UI.
2. Click the ID of the target application on the **All Applications** page. The application details page is displayed.



3. Click **Logs** of the application. On the displayed page, click **stdout** logs to view SQL inspection details.



NOTE

1. For more Spark SQL inspection rules, see **MRS SQL Inspection Rules**.
2. You can view query info in the **/opt/hadoopclient/Spark/spark/audit/query.log** path if you are using the Spark client. The log contains detailed running information and the corresponding SQL inspection information.

----End

10.13 Security Management

10.13.1 Security Overview

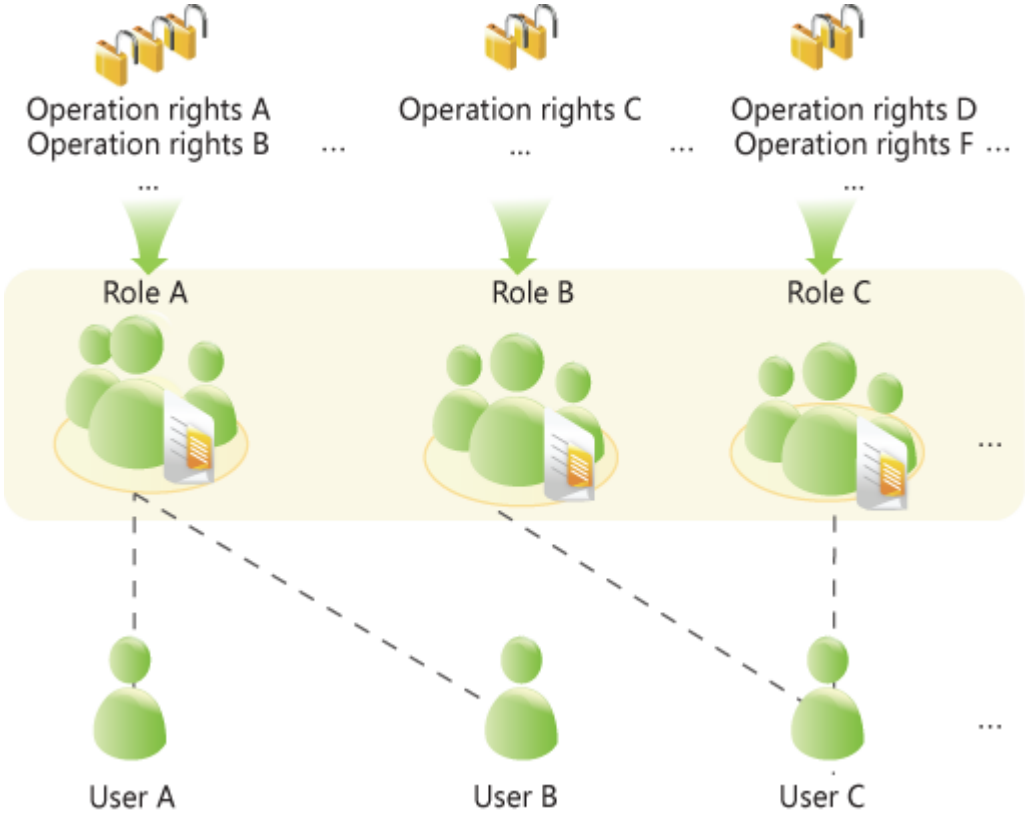
10.13.1.1 Right Model

Role-based Access Control

FusionInsight adopts the role-based access control (RBAC) mode to manage rights on the big data system. It integrates the right management functions of the components to centrally manage rights. Common users are shielded from internal right management details, and the right management operations are simplified for administrators, improving right management usability and user experience.

The right model of FusionInsight consists four parts, that is users, user groups, roles, and rights.

Figure 10-23 Right model



- **Right**

  Right, which is defined by components, allows users to access a certain resource of one component. Different components have different rights for their resources.

  For example:

  - HDFS provides read, write, and execute permissions on files.
  - HBase provides create, read, and write permissions on tables.

- **Role**

  Role is a collection of component rights. Each role can have multiple rights of multiple components. Different roles can have the rights of a resource of one component.

- **User group**

  User group is a collection of users. When a user group is bound to a role, users in this group obtain the rights defined by the role.

  Different user groups can be associated with the same role. A user group can also be associated with no role, and this user group does not have the rights of any component resources.

  NOTE

  In some components, the system grants related rights to specific user groups by default.

- **User**

  A user is a visitor to the system. Each user has the rights of the user group and role associated with the user. Users need to be added to the user group or associated with roles to obtain the corresponding rights.

Policy-based Access Control

The Ranger component uses policy-based access control (PBAC) to manage rights and implement fine-grained data access control on components such as HDFS, Hive, and HBase.

NOTE

The component supports only one right control mechanism. After the Ranger right control policy is enabled for the component, the right on the component in the role created on FusionInsight Manager becomes invalid (The ACL rules of HDFS and Yarn still take effect). You need to add a policy on the Ranger management page to grant rights on resources.

The Ranger right model consists of multiple right policies. A right policy consists of the following parts:

- Resource

  Resources are provided by components and can be accessed by users, such as HDFS files or folders, queues in Yarn, and databases, tables, and columns in Hive.

- User

  A User is a visitor to the system. The rights of each user are obtained based on the policy associated with the user. Information about users, user groups, and roles in the LDAP is periodically synchronized to the Ranger.

- Permission

  In a policy, you can configure various access conditions for resources, such as file read and write, permission conditions, rejection conditions, and exception conditions.

10.13.1.2 Right Mechanism

FusionInsight adopts the Lightweight Directory Access Protocol (LDAP) to store data of users and user groups. Information about role definitions is stored in the relational database and the mapping between roles and rights is saved in components.

FusionInsight uses Kerberos for unified authentication.

The verification process of user rights is as follows:

1. A client (a user terminal or FusionInsight component service) invokes the FusionInsight authentication interface.
2. FusionInsight uses the login username and password for Kerberos authentication.
3. If the authentication succeeds, the client sends a request for accessing the server (a FusionInsight component service).
4. The server finds the user group and role to which the login user belongs.
5. The server obtains all rights of the user group and the role.
6. The server checks whether the client has the right to access the resources it applies for.

Example (RBAC):

There are three files in HDFS, that is, fileA, fileB, and fileC.

- roleA has read and write right for fileA, and roleB has the read right for fileB.
- groupA is bound to roleA, and groupB is bound to roleB.
- userA belongs to groupA and roleB, and userB belongs to groupB.

When userA successfully logs in to the system and accesses the HDFS:

1. HDFS obtains the role (roleB) to which userA is bound.
2. HDFS also obtains the role (roleA) to which the user group of userA is bound.
3. In this case, userA has all the rights of roleA and roleB.
4. As a result, userA has read and write rights for fileA, has the read right on fileB, and has no right for fileC.

Similarly, when userB successfully logs in to the system and accesses the HDFS:

1. userB only has the rights of roleB.
2. As a result, userB has the read right on fileB, and has no rights for fileA and fileC.

10.13.1.3 Authentication Policies

The big data platform performs user identity authentication to prevent invalid users from accessing the cluster. The cluster provides authentication capabilities in both security mode and normal mode.

Security Mode

The clusters in security mode use the Kerberos authentication protocol for security authentication. The Kerberos protocol supports mutual authentication between

clients and servers. This eliminates the risks incurred by sending user credentials over the network for simulated authentication. In clusters, KrbServer provides the Kerberos authentication support.

Kerberos user object

In the Kerberos protocol, each user object is a principal. A complete principal consists of username and domain name. In O&M or application development scenarios, the user identity must be verified before a client connects to a server. Users for O&M and service operations are classified into human-machine and machine-machine users. The password of human-machine users is manually configured, while the password of machine-machine users is generated by the system randomly.

Kerberos authentication

Kerberos supports password and keytab authentication. The validity period of authentication is 24 hours by default.

- Password authentication: User identity is verified by entering the correct password. This mode mainly used in O&M scenarios where human-machine users are used. The configuration command is **kinit** *Username*.
- Keytab authentication: Keytab files contain users' principal and encrypted credential information. When keytab files are used for authentication, the system automatically uses encrypted credential information to perform authentication and the user password does not need to be entered. This mode is mainly used in component application development scenarios where machine-machine users are used. Keytab authentication can also be configured using the **kinit** command.

Normal Mode

Different components in a normal cluster use the native open-source authentication mode and do not support the **kinit** authentication command. FusionInsight Manager (including DBService, KrbServer, and LdapServer) uses the username and password for authentication. **Table 10-97** lists the authentication modes used by components.

Table 10-97 Component authentication modes

Service	Authentication Mode
IoTDB	Simple authentication
CDL	No authentication
ClickHouse	Simple authentication
Elasticsearch	Client: simple authentication
Flume	No authentication
FTP-Server	Username and password authentication
HBase	• Web UI: no authentication • Client: simple authentication

Service	Authentication Mode
HDFS	• Web UI: no authentication • Client: simple authentication
HetuEngine	• Web UI: no authentication • Client: no authentication
Hive	Simple authentication
Hue	Username and password authentication
Kafka	No authentication
Loader	• Web UI: username and password authentication • Client: no authentication
MapReduce	• Web UI: no authentication • Client: no authentication
Metadata	Username and password authentication
Oozie	• Web UI: username and password authentication • Client: simple authentication
Redis	No authentication
Solr	No authentication
Spark	• Web UI: no authentication • Client: simple authentication
Yarn	• Web UI: no authentication • Client: simple authentication
ZooKeeper	Simple authentication
MOTService	Username and password authentication
Containers	No authentication
RTDService	Username and password authentication
Guardian	No authentication
MemArtsCC	No authentication

The authentication modes are as follows:

- Simple authentication: When the client connects to the server, the client automatically authenticates the user (for example, the OS user **root** or **omm**) by default. The authentication is imperceptible to the administrator or service user, which does not require **kinit**.
- Username and password authentication: Use the username and password of human-machine users in the cluster for authentication.

- No authentication: Any user can access the server by default.

10.13.1.4 Permission Verification Policies

Security Mode

After a user is authenticated by the big data platform, the system determines whether to verify the user's permission based on the actual permission management configuration to ensure that the user has limited or all permission on resources. If the user does not have the permission for accessing cluster resources, the system administrator must grant the required permission to the user. Otherwise, the user fails to access the resources. The cluster provides permission verification capabilities in both security mode and normal mode. The specific permission items of the components are the same in the two modes.

By default, the Ranger service is installed and Ranger authentication is enabled for a newly installed cluster in security mode. You can set fine-grained security access policies for accessing component resources through the permission plug-in of the component. If Ranger authentication is not required, administrators can manually disable it on the service page. After Ranger authentication is disabled, the system continues to perform permission control based on the role model of FusionInsight Manager when accessing component resources.

In a cluster in security mode, the following components support Ranger authentication: HDFS, Yarn, Kafka, Hive, HBase, Elasticsearch, HetuEngine, CDL, and Spark.

For a cluster upgraded from an earlier version, Ranger authentication is not used by default when users access component resources. The administrator can manually enable Ranger authentication after installing Ranger.

By default, all components in the cluster of the security edition authenticate access. The authentication function cannot be disabled.

Normal Mode

Different components in a normal cluster use their own native open-source authentication behavior. **Table 10-98** lists detailed permission verification modes.

In a normal cluster, Ranger authentication can be used to perform permission control by OS user on components such as HBase, HDFS, Hive, Spark, and Yarn.

Table 10-98 Component permission verification modes in normal clusters

Service	Permission Verification	Permission Verification Enabling and Disabling
IoTDB	Required	Not supported
ClickHouse	Required	Not supported
Flume	Not required	Not supported
FTP-Server	Depends on HDFS permission verification	Not supported

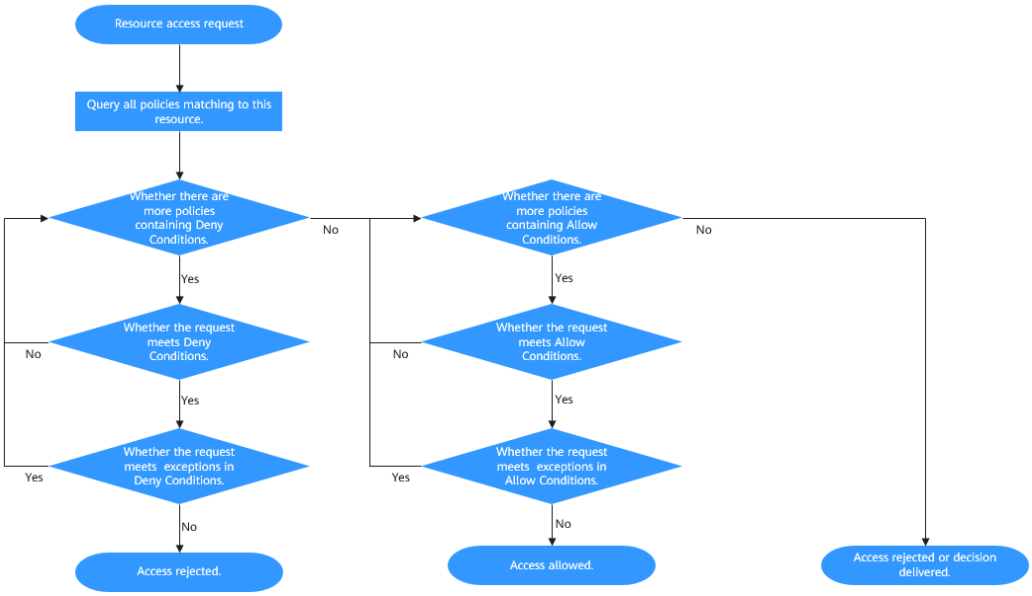
Service	Permission Verification	Permission Verification Enabling and Disabling
HBase	Not required	Supported
HDFS	Required	Supported
HetuEngine	Not required	Not supported
Hive	Not required	Not supported
Hue	Not required	Not supported
Kafka	Not required	Not supported
Loader	Not required	Not supported
MapReduce	Not required	Not supported
Metadata	Not required	Not supported
Oozie	Required	Not supported
Redis	Not required	Not supported
Solr	Not required	Not supported
Spark	Not required	Not supported
Yarn	Not required	Supported
ZooKeeper	Required	Supported
CDL	Not required	Not supported
Elasticsearch	Not required	Not supported
Containers	Not required	Not supported
RTDService	Required	Not supported
MOTService	Required	Supported
Doris	Required	Not supported
Guardian	Not required	Not supported
MemArtsCC	Not required	Not supported

Condition Priorities of the Ranger Permission Policy

When configuring a permission policy for a resource, you can configure Allow Conditions, Exclude from Allow Conditions, Deny Conditions, and Exclude from Deny Conditions for the resource, to meet unexpected requirements in different scenarios.

The priorities of different conditions are listed in descending order: Exclude from Deny Conditions > Deny Conditions > Exclude from Allow Conditions > Allow Conditions

The following figure shows the process of determining condition priorities. If the component resource request does not match the permission policy in Ranger, the system rejects the access by default. However, for HDFS and Yarn, the system delivers the decision to the access control layer of the component for determination.



For example, if you want to grant the read and write permissions of the **FileA** folder to the **groupA** user group, but the user in the group is not **UserA**, you can add an allowed condition and an exception condition.

10.13.1.5 User Account List

User Classification

There are three types of users available in MRS clusters. Do not use the default passwords. Change the passwords periodically.

NOTE

This section describes the default users in the MRS cluster.

User Type	Description
System users	• User created on FusionInsight Manager for O&M and service scenarios. There are two types of users: – **Human-machine** user: used in scenarios such as FusionInsight Manager O&M and operations on a component client. When creating a user of this type, you need to set password and confirm password by referring to **Creating a User**. – **Machine-machine** user: used for system application development. • User who runs OMS processes

User Type	Description
Internal system users	Internal user to perform Kerberos authentication, process communications, save user group information, and associate user permissions. It is recommended that internal system users not be used in O&M scenarios. Operations can be performed as user **admin** or another user created by the system administrator based on service requirements.
Database users	• User who manages OMS database and accesses data • User who runs service components (Hue, Hive, HetuEngine, Metadata, Loader, Oozie, Redis, Ranger, JobGateway, and DBService) in the database.

System Users

NOTE

- User **root** of the OS is required, the password of user **root** on all nodes must be the same.
- User **ldap** of the OS is required. Do not delete this account. Otherwise, the cluster may not work properly. The OS administrator maintains the password management policies.

User Type	Username	Description	Password Change Method
System administrator	admin	FusionInsight Manager administrator. **NOTE** By default, user **admin** does not have the management permission on other components. For example, when accessing the native UI of a component, the user fails to access the complete component information due to insufficient management permission on the component.	For details, see **Changing the Password for User admin**.
Node OS user	ommdba	User that creates the system database. This user is an OS user generated on the management node and does not require a unified password. This account cannot be used for remote login.	For details, see **Changing the Password for an OS User**.

User Type	Username	Description	Password Change Method
	omm	Internal running user of the system. This user is an OS user generated on all nodes and does not require a unified password.	

Internal System Users

User Type	Default User	Description	Password Change Method
Kerberos administrator	kadmin/admin	Used to add, delete, modify, and query user accounts on Kerberos.	For details, see **Changing the Password for the Kerberos Administrator**.
OMS Kerberos administrator	kadmin/admin	Used to add, delete, modify, and query user accounts on OMS Kerberos.	For details, see **Changing the Password for the OMS Kerberos Administrator**.
LDAP administrator	cn=root,dc=hadoop,dc=com	Used to add, delete, modify, and query the user account information on LDAP.	For details, see **Modifying OMS Service Configuration Parameters**.
OMS LDAP administrator	cn=root,dc=hadoop,dc=com	Used to add, delete, modify, and query the user account information on OMS LDAP.	
LDAP user	cn=pg_search_dn,ou=Users,dc=hadoop,dc=com	Used to query information about users and user groups on LDAP.	
OMS LDAP user	cn=pg_search_dn,ou=Users,dc=hadoop,dc=com	Used to query information about users and user groups on OMS LDAP.	
LDAP administrator account	cn=krbkdc,ou=Users,dc=hadoop,dc=com	Used to query Kerberos component authentication account information.	For details, see **Modifying OMS Service Configuration Parameters**.

User Type	Default User	Description	Password Change Method
	cn=krbadmin,ou=Users,dc=hadoop,dc=com	Used to add, delete, modify, and query Kerberos component authentication account information.	
Component running user	iotdb	This user is the IoTDB system administrator and has the following user permissions: 1. IoTDB administrator permissions: • Creates and deletes databases. • Uses TTL. 2. IoTDB data operation permissions: • Creates, modifies, and deletes a time sequence. • Writes, reads, and deletes data in a time sequence. 3. Views user or role permission information. 4. Grants or revokes permissions to or from a user or role. **NOTE** In a common cluster, the IoTDB service retains the open-source feature. The default username is **root**. This user is an administrator and has all permissions, which cannot be assigned, revoked, or deleted.	For details, see **Changing the Password for a Component Running User**.

User Type	Default User	Description	Password Change Method
	hdfs	This user is the HDFS system administrator and has the following permissions: 1. File system operation permissions: ● Views, modifies, and creates files. ● Views and creates directories. ● Views and modifies the groups where files belong. ● Views and sets disk quotas for users. 2. HDFS management operation permissions: ● Views the web UI status. ● Views and sets the active and standby HDFS status. ● Enters and exits the HDFS in security mode. ● Checks the HDFS file system. 3. Logs in to the FTP service page.	

User Type	Default User	Description	Password Change Method
	hbase	This user is the HBase and HBase1 to HBase4 system administrator and has the following permissions: ● Cluster management permission: Performs **Enable** and **Disable** operations on tables to trigger MajorCompact and ACL operations. ● Grants and revokes permissions, and shuts down the cluster. ● Table management permission: Creates, modifies, and deletes tables. ● Data management permission: Reads data in tables, column families, and columns. ● Logs in to the HMaster web UI. ● Logs in to the FTP service page.	

User Type	Default User	Description	Password Change Method
	mapred	This user is the MapReduce/Yarn system administrator and has the following permissions: ● Submits, stops, and views the MapReduce tasks. ● Modifies the Yarn configuration parameters. ● Logs in to the FTP service page. ● Logs in to the Yarn web UI.	
	zookeeper	This user is the ZooKeeper system administrator and has the following permissions: ● Adds, deletes, modifies, and queries all nodes in ZooKeeper. ● Modifies and queries quotas of all nodes in ZooKeeper.	

User Type	Default User	Description	Password Change Method
	solr	This user has the Solr system management permissions and user permissions: ● Accesses the Solr Admin UI. ● Management of configuration files: Uploads a Solr configuration file to a ZooKeeper directory and modifies the Solr configuration file in the ZooKeeper directory. ● Management of index collections: Creates, deletes, and views collections. ● Operations on index data: Creates, deletes, and views indexes.	
	Elasticsearch	This user has the Elasticsearch system management permissions and user permissions: ● Management of index collections: Creates, deletes, and views index collections. ● Operations on index data: Creates, deletes, and views indexes.	
	rangerkms	RangerKMS system administrator	

User Type	Default User	Description	Password Change Method
	rangeradmin	This user has the Ranger system management permissions and user permissions: • Ranger web UI management permission • Management permission of each component that uses Ranger authentication	
	rangerauditor	Default audit user of the Ranger system.	

User Type	Default User	Description	Password Change Method
	hive	This user is the Hive system administrator and has the following permissions: 1. Hive administrator permissions: ● Creates, deletes, and modifies a database. ● Creates, queries, modifies, and deletes a table. ● Queries, inserts, and uploads data. 2. HDFS file operation permissions: ● Views, modifies, and creates files. ● Views and creates directories. ● Views and modifies the groups where files belong. 3. Submits and stops the MapReduce tasks. 4. Ranger policy management permission	

User Type	Default User	Description	Password Change Method
	hive1	This user is the Hive1 system administrator and has the following permissions: 1. Hive1 administrator permissions: ● Creates, deletes, and modifies a database. ● Creates, queries, modifies, and deletes a table. ● Queries, inserts, and uploads data. 2. HDFS file operation permissions: ● Views, modifies, and creates files. ● Views and creates directories. ● Views and modifies the groups where files belong. 3. Submits and stops the MapReduce tasks. 4. Ranger policy management permission	

User Type	Default User	Description	Password Change Method
	hive2	This user is the Hive2 system administrator and has the following permissions: 1. Hive2 administrator permissions: ● Creates, deletes, and modifies a database. ● Creates, queries, modifies, and deletes a table. ● Queries, inserts, and uploads data. 2. HDFS file operation permissions: ● Views, modifies, and creates files. ● Views and creates directories. ● Views and modifies the groups where files belong. 3. Submits and stops the MapReduce tasks. 4. Ranger policy management permission	

User Type	Default User	Description	Password Change Method
	hive3	This user is the Hive3 system administrator and has the following permissions: 1. Hive3 administrator permissions: ● Creates, deletes, and modifies a database. ● Creates, queries, modifies, and deletes a table. ● Queries, inserts, and uploads data. 2. HDFS file operation permissions: ● Views, modifies, and creates files. ● Views and creates directories. ● Views and modifies the groups where files belong. 3. Submits and stops the MapReduce tasks. 4. Ranger policy management permission	

User Type	Default User	Description	Password Change Method
	hive4	This user is the Hive4 system administrator and has the following permissions: 1. Hive4 administrator permissions: ● Creates, deletes, and modifies a database. ● Creates, queries, modifies, and deletes a table. ● Queries, inserts, and uploads data. 2. HDFS file operation permissions: ● Views, modifies, and creates files. ● Views and creates directories. ● Views and modifies the groups where files belong. 3. Submits and stops the MapReduce tasks. 4. Ranger policy management permission	

User Type	Default User	Description	Password Change Method
	kafka	This user is the Kafka system administrator and has the following permissions: • Creates, deletes, produces, and consumes the topic; modifies the topic configuration. • Controls the cluster metadata, modifies the configuration, migrates the replica, elects the leader, and manages ACL. • Submits, queries, and deletes the consumer group offset. • Queries the delegation token. • Queries and submits the transaction.	
	cdl	CDL system administrator Currently, user permissions are not involved in CDL.	
	rangerusersync	Synchronizes users and internal users of user groups.	
	rangertagsync	Internal user for synchronizing tags.	
	oms/manager	Controller and NodeAgent authentication user. The user has the permission on the **supergroup** group.	

User Type	Default User	Description	Password Change Method
	backup/manager	User for running backup and restoration tasks. The user has the permission on the **supergroup**, **wheel**, and **ficommon** groups. After cross-system mutual trust is configured, the user has the permission to access data in the HDFS, HBase, Hive, and ZooKeeper systems.	

User Type	Default User	Description	Password Change Method
	hdfs/ hadoop.<*System domain name*>	This user is used to start the HDFS and has the following permissions: 1. File system operation permissions: ● Views, modifies, and creates files. ● Views and creates directories. ● Views and modifies the groups where files belong. ● Views and sets disk quotas for users. 2. HDFS management operation permissions: ● Views the web UI status. ● Views and sets the active and standby HDFS status. ● Enters and exits the HDFS in security mode. ● Checks the HDFS file system. 3. Logs in to the FTP service page.	

User Type	Default User	Description	Password Change Method
	hetuserver/hadoop.*<System domain name>*	This user is used to start HetuEngine and has the following permissions: ● Accesses KrbServer and HDFS files in the cluster from HetuEngine. ● Used for communication between HetuEngine internal nodes.	
	mapred/hadoop.*<System domain name>*	This user is used to start the MapReduce and has the following permissions: ● Submits, stops, and views the MapReduce tasks. ● Modifies the Yarn configuration parameters. ● Logs in to the FTP service page. ● Logs in to the Yarn web UI.	
	mr_zk/hadoop.*<System domain name>*	Used for MapReduce to access ZooKeeper.	
	hbase/hadoop.*<System domain name>*	User for the authentication between internal components during the HBase system startup.	
	hbase/zkclient.*<System domain name>*	User for HBase to perform ZooKeeper authentication in a security mode cluster.	
	thrift/hadoop.*<System domain name>*	ThriftServer system startup user.	

User Type	Default User	Description	Password Change Method
	rangerkms/hadoop.*<System domain name>*	RangerKMS system startup user	
	rest/hadoop.*<System domain name>*	RestServer system startup user.	
	thrift/*<hostname>*	User for the ThriftServer system to access HBase. This user has the read, write, execution, creation, and administration permission on all NameSpaces and tables of HBase. *<hostname>* indicates the name of the host where the ThriftServer node is installed in the cluster.	

User Type	Default User	Description	Password Change Method
	hive/ hadoop.<*System domain name*>	User for the authentication between internal components during the Hive system startup. The user permissions are as follows: 1. Hive administrator permissions: ● Creates, deletes, and modifies a database. ● Creates, queries, modifies, and deletes a table. ● Queries, inserts, and uploads data. 2. HDFS file operation permissions: ● Views, modifies, and creates files. ● Views and creates directories. ● Views and modifies the groups where files belong. 3. Submits and stops the MapReduce tasks.	

User Type	Default User	Description	Password Change Method
	hive1/ hadoop.*<System domain name>*	User for the authentication between internal components during the Hive1 system startup. The user permissions are as follows: 1. Hive1 administrator permissions: ● Creates, deletes, and modifies a database. ● Creates, queries, modifies, and deletes a table. ● Queries, inserts, and uploads data. 2. HDFS file operation permissions: ● Views, modifies, and creates files. ● Views and creates directories. ● Views and modifies the groups where files belong. 3. Submits and stops the MapReduce tasks.	

User Type	Default User	Description	Password Change Method
	hive2/ hadoop.<*System domain name*>	User for the authentication between internal components during the Hive2 system startup. The user permissions are as follows: 1. Hive2 administrator permissions: ● Creates, deletes, and modifies a database. ● Creates, queries, modifies, and deletes a table. ● Queries, inserts, and uploads data. 2. HDFS file operation permissions: ● Views, modifies, and creates files. ● Views and creates directories. ● Views and modifies the groups where files belong. 3. Submits and stops the MapReduce tasks.	

User Type	Default User	Description	Password Change Method
	hive3/ hadoop.*<System domain name>*	User for the authentication between internal components during the Hive3 system startup. The user permissions are as follows: 1. Hive3 administrator permissions: ● Creates, deletes, and modifies a database. ● Creates, queries, modifies, and deletes a table. ● Queries, inserts, and uploads data. 2. HDFS file operation permissions: ● Views, modifies, and creates files. ● Views and creates directories. ● Views and modifies the groups where files belong. 3. Submits and stops the MapReduce tasks.	

User Type	Default User	Description	Password Change Method
	hive4/ hadoop.*<System domain name>*	User for the authentication between internal components during the Hive4 system startup. The user permissions are as follows: 1. Hive4 administrator permissions: • Creates, deletes, and modifies a database. • Creates, queries, modifies, and deletes a table. • Queries, inserts, and uploads data. 2. HDFS file operation permissions: • Views, modifies, and creates files. • Views and creates directories. • Views and modifies the groups where files belong. 3. Submits and stops the MapReduce tasks.	
	loader/ hadoop.*<System domain name>*	User for Loader system startup and Kerberos authentication	
	HTTP/ *<hostname>*	Used to connect to the HTTP interface of each component. *<hostname>* indicates the host name of a node in the cluster.	

User Type	Default User	Description	Password Change Method
	hue	User for Hue system startup, Kerberos authentication, and HDFS and Hive access	
	flume	User for Flume system startup and HDFS and Kafka access. The user has read and write permission of the HDFS directory **/flume**.	
	flume_server	User for Flume system startup and HDFS and Kafka access. The user has read and write permission of the HDFS directory **/flume**.	
	ftpserver	FTP-Server system startup user.	
	metadata/ hadoop.*<System domain name>*	Metadata system startup user who can access Hive and HBase metadata.	
	spark_zk/ hadoop.*<System domain name>*	Used for Spark to access ZooKeeper.	
	spark2x/ hadoop.*<System domain name>*	This user is the Spark system administrator and has the following user permissions: 1. Starts the Spark service. 2. Submits Spark tasks.	
	spark2x1/ hadoop.*<System domain name>*	This user is the Spark1 system administrator and has the following user permissions: 1. Starts the Spark1 service. 2. Submits Spark tasks.	

User Type	Default User	Description	Password Change Method
	spark2x2/hadoop.*<System domain name>*	This user is the Spark2 system administrator and has the following user permissions: 1. Starts the Spark2 service. 2. Submits Spark tasks.	
	spark2x3/hadoop.*<System domain name>*	This user is the Spark3 system administrator and has the following user permissions: 1. Starts the Spark3 service. 2. Submits Spark tasks.	
	spark2x4/hadoop.*<System domain name>*	This user is the Spark4 system administrator and has the following user permissions: 1. Starts the Spark4 service. 2. Submits Spark tasks.	
	zookeeper/hadoop.*<System domain name>*	ZooKeeper system startup user.	
	zkcli/hadoop.*<System domain name>*	ZooKeeper server login user.	
	oozie	User for Oozie system startup and Kerberos authentication.	

User Type	Default User	Description	Password Change Method
	solr/ hadoop.*<System domain name>*	• Used to access the HDFS data directory. The HDFS Solr data directory is **/user/solr** and the user has the read and write permission of the directory. • Used to access the ZooKeeper data directory. The user can access all the files in the **/solr** directory in ZooKeeper and has the read and write permission of all the files in the directory.	
	elasticsearch/ hadoop.*<System domain name>*	Used to access the ZooKeeper data directory. The user can access all the files in the **/elasticsearch** directory in ZooKeeper and has the read and write permission of all the files in the directory.	
	HTTP/ *<hostname>*	Used to perform Kerberos authentication on the HTTP service of Solr.	
	HTTP/ SOLR_FLOAT_IP	Used to perform Kerberos authentication on the HTTP service of Solr.	
	kafka/ hadoop.*<System domain name>*	Used for security authentication of Kafka.	
	redisCli	Redis system administrator	

User Type	Default User	Description	Password Change Method
	redis/hadoop.*<System domain name>*	Redis system startup user	
	flink/hadoop.*<System domain name>*	Internal user of the Flink service.	
	check_ker_M	User who performs a system internal test about whether the Kerberos service is normal.	
	tez	User for TezUI system startup, Kerberos authentication, and access to Yarn	
	cdl/hadoop.*<System domain name>*	Internal user of the CDL service.	
	rangeradmin/hadoop.*<System domain name>*	Ranger system startup user, which is used for authentication between internal components.	
	clickhouse/hadoop.*<System domain name>*	Used for security authentication of ClickHouse. This user is an internal user and can be used only in the cluster.	• Security mode: see **Changing the Password for a Component Running User**. • Normal mode: see "Configuring the Password of the Default Account of a ClickHouse Cluster" in .
	default	ClickHouse internal user, which is an administrator user that can be used only in non-security mode.	For details, see "Configuring the Password of the Default Account of a ClickHouse Cluster" in .

User Type	Default User	Description	Password Change Method
	K/M	Kerberos internal functional user. It cannot be deleted, and its password cannot be changed. This internal account can only be used on nodes where Kerberos service is installed.	None
	kadmin/changepw		
	kadmin/history		
	krbtgt<*System domain name*>		
	root	Used in Doris internally to initialize the **doris_manager** user.	None
	admin	Doris internal user of common clusters	After you can connect to Doris as user **admin**, run **SET PASSWORD = PASSWORD('***password***');** to change the password. Commands carrying authentication passwords pose security risks. Disable historical command recording before running such commands to prevent information leakage.
	doris_manager	Used in Doris internally to add instance, users, and roles	None
	doris	Doris internal user, which is used by Hive Catalog to access other components when Kerberos authentication is enabled for the cluster (the cluster is in security mode).	None

User Type	Default User	Description	Password Change Method
	doris/hadoop.*<System domain name>*	Doris internal user, which is used by Hive Catalog to access other components when Kerberos authentication is enabled for the cluster (the cluster is in security mode).	None
Component running user	rangerobs/hadoop.*<System domain name>*	System administrator used by Guardian to access Ranger	For details, see **Changing the Password for a Component Running User**.
Component running user	jobserver	This user is the JobGateway system administrator and has the following permissions: 1. HDFS file operations: • Views, modifies, and creates files. • Views and creates directories. • Views and modifies the groups where files belong. 2. Manager administrator permission	For details, see **Changing the Password for a Component Running User**.
Component running user	HTTP/_HOST	Internal user of the JobGateway service, which is used for Kerberos authentication of the HTTP service	For details, see **Changing the Password for a Component Running User**.

User Type	Default User	Description	Password Change Method
LDAP user	admin	FusionInsight Manager administrator. The primary group is **compcommon**, which does not have the group permission but has the permission of the **Manager_administrator** role.	The LDAP user cannot log in to the system, and the password cannot be changed.
	backup	The primary group is **compcommon**.	
	backup/manager	The primary group is **compcommon**.	
	oms	The primary group is **compcommon**.	
	oms/manager	The primary group is **compcommon**.	
	clientregister	The primary group is **compcommon**.	
	zookeeper	The primary group is **hadoop**.	
	zookeeper/hadoop.*<System domain name>*	The primary group is **hadoop**.	
	zkcli	The primary group is **hadoop**.	
	zkcli/hadoop.*<System domain name>*	The primary group is **hadoop**.	
	flume	The primary group is **hadoop**.	
	flume_server	The primary group is **hadoop**.	
	ftpserver	The primary group is **supergroup**.	
	hdfs	The primary group is **hadoop**.	

User Type	Default User	Description	Password Change Method
	hdfs/ hadoop.*<System domain name>*	The primary group is **hadoop**.	
	mapred	The primary group is **hadoop**.	
	mapred/ hadoop.*<System domain name>*	The primary group is **hadoop**.	
	mr_zk	The primary group is **hadoop**.	
	mr_zk/ hadoop.*<System domain name>*	The primary group is **hadoop**.	
	hue	The primary group is **supergroup**.	
	hive	The primary group is **hive**.	
	hive/ hadoop.*<System domain name>*	The primary group is **hive**.	
	hive1	The primary group is **hive1**.	
	hive1/ hadoop.*<System domain name>*	The primary group is **hive1**.	
	hive2	The primary group is **hive2**.	
	hive2/ hadoop.*<System domain name>*	The primary group is **hive2**.	
	hive3	The primary group is **hive3**.	
	hive3/ hadoop.*<System domain name>*	The primary group is **hive3**.	
	hive4	The primary group is **hive4**.	

User Type	Default User	Description	Password Change Method
	hive4/hadoop.*<System domain name>*	The primary group is **hive4**.	
	hbase	The primary group is **hadoop**.	
	hbase/hadoop.*<System domain name>*	The primary group is **hadoop**.	
	thrift	The primary group is **hadoop**.	
	thrift/hadoop.*<System domain name>*	The primary group is **hadoop**.	
	oozie	The primary group is **hadoop**.	
	hbase/zkclient.*<System domain name>*	The primary group is **hadoop**.	
	loader	The primary group is **hadoop**.	
	loader/hadoop.*<System domain name>*	The primary group is **hadoop**.	
	spark2x	The primary group is **hadoop**.	
	spark2x/hadoop.*<System domain name>*	The primary group is **hadoop**.	
	spark2x1	The primary group is **hadoop**.	
	spark2x1/hadoop.*<System domain name>*	The primary group is **hadoop**.	
	spark2x2	The primary group is **hadoop**.	
	spark2x2/hadoop.*<System domain name>*	The primary group is **hadoop**.	

User Type	Default User	Description	Password Change Method
	spark2x3	The primary group is **hadoop**.	
	spark2x3/hadoop.*<System domain name>*	The primary group is **hadoop**.	
	spark2x4	The primary group is **hadoop**.	
	spark2x4/hadoop.*<System domain name>*	The primary group is **hadoop**.	
	metadata	The primary group is **supergroup**.	
	metadata/hadoop.*<System domain name>*	The primary group is **supergroup**.	
	kafka	The primary group is **kafkaadmin**.	
	kafka/hadoop.*<System domain name>*	The primary group is **kafkaadmin**.	
	cdl	The primary group is **cdladmin**.	
	cdl/hadoop.*<System domain name>*	The primary group is **cdladmin**.	
	redisCli	The primary group is **supergroup**.	
	redis	The primary group is **supergroup**.	
	redis/hadoop.*<System domain name>*	The primary group is **supergroup**.	
	solr	The primary group is **ficommon**.	
	solr/hadoop.*<System domain name>*	The primary group is **ficommon**.	
	Elasticsearch	The primary group is **ficommon**.	

User Type	Default User	Description	Password Change Method
	elasticsearch/ hadoop.*<System domain name>*	The primary group is **ficommon**.	
	rangeradmin	The primary group is **supergroup**.	
	rangeradmin/ hadoop.*<System domain name>*	The primary group is **supergroup**.	
	rangerusersync	The primary group is **supergroup**.	
	rangertagsync	The primary group is **supergroup**.	
	rangerauditor	The primary group is **compcommon**.	
	kms/hadoop	The primary group is **kmsadmin**.	
	knox	The primary group is **compcommon**.	
	executor	The primary group is **compcommon**.	
	doris	The primary group is **supergroup**.	
	doris/ hadoop.*<System domain name>*	The primary group is **supergroup**.	
LDAP user	jobserver	The primary group is **compcommon**.	The LDAP user cannot log in to the system, and the password cannot be changed.

NOTE

Log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and check the value of **Local Domain**. In the preceding table, all letters in the system domain name contained in the username of the system internal user are lowercase letters.

For example, if **Local Domain** is set to **9427068F-6EFA-4833-B43E-60CB641E5B6C.COM**, the username of default HDFS startup user is **hdfs/hadoop.9427068f-6efa-4833-b43e-60cb641e5b6c.com**.

Database Users

The system database users include OMS database users and DBService database users.

Database Type	Default User	Description	Password Change Method
OMS database	ommdba	OMS database administrator who performs maintenance operations, such as creating, starting, and stopping.	For details, see **Changing the Password of the OMS Database Administrator**.
	omm	User for accessing OMS database data	For details, see **Changing the Password for the Data Access User of the OMS Database**.
DBService database	omm	Administrator of the GaussDB database in the DBService component	For details, see **Resetting the Password for User omm in DBService**.
	compdbuser	Administrator of the GaussDB database in the DBService component. It is used in service O&M scenarios. If the password of this account has expired, you need to reset the password upon your first login.	For details, see **Changing the Password for User compdbuser of the DBService Database**.
	hetu	User for HetuEngine to connect to the DBService database **hetumeta**.	For details, see **Resetting the Component Database User Password**.
	hive	User for Hive to connect to the DBService database **hivemeta**.	
	hive1	User for Hive1 to connect to the DBService database **hivemeta1**.	
	hive2	User for Hive2 to connect to the DBService database **hivemeta2**.	

Database Type	Default User	Description	Password Change Method
	hive3	User for Hive3 to connect to the DBService database **hivemeta3**.	
	hive4	User for Hive4 to connect to the DBService database **hivemeta4**.	
	hive*N*/*N*	User for **Hive-***N* to connect to the DBService database **hive***N*/***N*meta** when multiple services are installed. For example, the user for **Hive-1** to connect to the DBService database **hive1meta** is **hive11**.	
	hue	User for Hue to connect to the DBService database **hue**.	
	sqoop	User for Loader to connect to the DBService database **sqoop**.	
	sqoop*N*	User for **Loader-***N* to connect to the DBService database **sqoop***N* when multiple services are installed. For example, the user for **Loader-1** to connect to the DBService database **sqoop1** is **sqoop1**.	
	metadata	User for Metadata to connect to the DBService database **metadata**.	

Database Type	Default User	Description	Password Change Method
	metadata*N*	User for **Metadata-*N*** to connect to the DBService database **metadata*N*** when multiple services are installed. For example, the user for **Metadata-1** to connect to the DBService database **metadata1** is **metadata1**.	
	oozie	User for Oozie to connect to the DBService database **oozie**.	
	oozie*N*	User for **Oozie-*N*** to connect to the DBService database **oozie*N*** when multiple services are installed. For example, the user for **Oozie-1** to connect to the DBService database **oozie1** is **oozie1**.	
	redis	User for Redis to connect to the DBService database **redismeta**.	
	rangeradmin	User for Ranger to connect to the DBService database **ranger**.	
	kafkaui*N*	User for Kafka UI to connect to the DBService database **kafkaui**.	
	flink	User for Flink to connect to the DBService database **flink**.	

Database Type	Default User	Description	Password Change Method
	cdl	User for CDL to connect to the DBService database **cdl**.	
	activiti	User for Containers to connect to the DBService database **activitidb**.	
	rtd	User for RTDService to connect to the DBService database **rtdmeta**.	
	lakesearch	User for LakeSearch to connect to the DBService database **lakesearch**.	
	jobgateway	User for JobGateway to connect to the DBService database **jobmeta**.	
MOTService database	omm	Administrator of the database in the MOTService component	Contact the system administrator to obtain the password.

10.13.1.6 Default Permission Information

Role

Default Role	Description
Manager_administrator	Manager administrator who has all permissions for Manager. Manager administrators can create first-level tenants, create and modify user groups, and specify user permissions.
Manager_operator	Manager operator who has all the permissions on the **Homepage**, **Cluster**, **Hosts**, and **O&M** tab pages.
Manager_auditor	Manager auditor who has all permissions on the **Audit** tab page. Manager auditors can view and manage Manager system audit logs.

Default Role	Description
Manager_viewer	Manager viewer who has the permission to view information about **Homepage**, **Cluster**, **Hosts**, **Alarm**, **Events**, and **System > Permission**, and download clients.
Manager_tenant	Manager tenant administrator. This role can create and manage sub-tenants for the non-leaf tenants to which the current user belongs. It has the permission to view alarms and events on **O&M > Alarm**.
System_administrator	System administrator, this role has Manager system administrator rights and all services administrator rights.
default	This role is the default role created for the **default** tenant. It has the management permissions on the Yarn component and the default queue. The default role of the default tenant that is not the first cluster to be installed is **c***<cluster ID>*_**default**.
Manager_administrator_180	FusionInsight Manager system administrator group. Internal system user group, which is used only between components.
Manager_auditor_181	FusionInsight Manager system auditor group. Internal system user group, which is used only between components.
Manager_operator_182	FusionInsight Manager system operator group. Internal system user group, which is used only between components.
Manager_viewer_183	FusionInsight Manager system viewer group. Internal system user group, which is used only between components.
System_administrator_186	System administrator group. Internal system user group, which is used only between components.
Manager_tenant_187	Tenant system user group. Internal system user group, which is used only between components.
default_1000	This group is created for tenant. Internal system user group, which is used only between components.

User group

Type	Default User Group	Description
Default cluster user groups	cdl	Common user group of CDL. Users in this group can create and query CDL jobs.
	cdladmin	CDL administrator group. Only users in this group can access CDL APIs.
	Elasticsearch	Users added to this user group can use Elasticsearch.
	graphbaseadmin	GraphBase administrator group. Users added to this user group will have the administrator rights of GraphBase and GraphServer.
	graphbasedeveloper	GraphBase developer group. Users added to this user group will have the developer rights of GraphBase and GraphServer.
	graphbaseoperator	GraphBase operator group. Users in this group have the permission to query data on the GraphServer web UI.
	hadoop	Users added to this group are granted the permission to submit all Yarn queue tasks.
	hadoopmanager	Users added to this user group can have the O&M manager rights of HDFS and Yarn. The O&M manager of HDFS can access the NameNode WebUI and perform active to standby switchover manually. The O&M manager of Yarn can access the ResourceManager WebUI, operate NodeManager nodes, refresh queues, and set node labels, but cannot submit tasks.
	hetuadmin	HetuEngine administrator group. Users in this group have the permission to perform operations on HSConsole.
	hetuuser	User group to which the users need to be added to obtain the SQL execution permission
	hive/hive1/hive2/hive3/hive4	Common user group. Hive/Hive1/Hive2/Hive3/Hive4 users must be in this user group.
	iotdbgroup	Users added to this user group have the administrator rights of the IoTDB component.
	kafka	Kafka common user group. A user in this group can access a topic only when a user in the kafkaadmin group grants the read and write permission of the topic to the user.
	kafkaadmin	Kafka administrator group. Users in this group have the rights to create, delete, authorize, read, and write all topics.

Type	Default User Group	Description
	kafkasuperuser	Topic read/write user group of Kafka. Users added to this group have the read and write permissions on all topics.
	kafkaui	Kafka UI user group. Users in this group have the permission to view Kafka UI.
	kmsadmin	After a user is added to the user group, the read permission on all keys in the KMS can be obtained.
	lakesearchgroup	Users added to this user group have the administrator rights of the LakeSearch component.
	msadmin	Users added to this user group have the administrator rights of Metastore.
	rkmsadmin	User group for RangerKMS permission management. If the key management permission is required, add the user to this group.
	solr	Users added to this user group can use Solr.
	supergroup	Users added to this user group can have the administrator rights of HBase, HDFS, Solr, Redis, and Yarn and can use Hive.
	yarnviewgroup	Indicates the read-only user group of the Yarn task. Users in this user group can have the view permission on Yarn and MapReduce tasks.
	check_sec_ldap	Perform internal test on the active LDAP to see whether it works properly. This user group is generated randomly in a test and automatically deleted after the test is complete. Internal system user group, which is used only between components.
	compcommon	System internal group for accessing cluster system resources. All system users and system running users are added to this user group by default.
OS user groups	wheel	Primary group of the FusionInsight internal running user omm.
	ficommon	System common group that corresponds to **compcommon** for accessing cluster common resource files stored in the OS.

NOTE

If the current cluster is not the cluster that is installed for the first time in FusionInsight Manager, the default user group name of all components except Manager in the cluster is **c***<cluster ID>_ default user group name*, for example, **c2_hadoop**.

Service-related User Security Parameters

- **FTP-Server**
  - The **ftp-group** parameter specifies the user group to which common users who are allowed to connect to the FTP server belong. If the users are not added to the corresponding user group, they cannot connect to the FTP server. The default value is **hadoop**.
  - The **ftp-admin-group** parameter specifies the user group to which the administrator of the FTP server belongs. If the administrator is not added to the corresponding user group, the administrator cannot operate directories and files of other users. The default value is **supergroup**.
- **HDFS**

  The **dfs.permissions.superusergroup** parameter specifies the administrator group with the highest permission on the HDFS. The default value is **supergroup**.
- **Spark and Corresponding Multi-Instances**

  The **spark.admin.acls** parameter indicates the Spark administrator list. Members in the list have the permission to manage all Spark tasks. If a user is not added to the list, the user cannot manage all Spark tasks. The default value is **admin**.

10.13.1.7 FusionInsight Manager Security Functions

You can query and set user rights data through the following FusionInsight Manager modules:

- User management: Users can be added, deleted, modified, queried, bound to user groups, and assigned with roles.

  For details, see **Managing Users**.
- User group management: User groups can be added, deleted, modified, queried, and bound to roles.

  For details, see **Managing User Groups**.
- Role management: Roles can be added, deleted, modified, queried, and assigned with the resource access rights of one or multiple components.

  For details, see **Managing Roles**.
- Tenant management: Tenants can be added, deleted, modified, queried, and bound to component resources. FusionInsight generates a role for each tenant to facilitate management. If a tenant is assigned with the rights of some resources, its corresponding role also has these rights.

  For details, see **Tenant Resources**.

10.13.2 Account Management

10.13.2.1 Account Security Settings

10.13.2.1.1 Unlocking LDAP Users and Management Accounts

Scenario

If the LDAP user **cn=pg_search_dn,ou=Users,dc=hadoop,dc=com** and LDAP management accounts **cn=krbkdc,ou=Users,dc=hadoop,dc=com** and **cn=krbadmin,ou=Users,dc=hadoop,dc=com** are locked, the administrator must unlock these accounts.

NOTE

If you input an incorrect password for the LDAP user or management account for five consecutive times, the LDAP user or management account is locked. The account is automatically unlocked after 5 minutes.

Procedure

Step 1 Log in to the active management node as user **omm**.

Step 2 Run the following command to go to the related directory:

cd ${BIGDATA_HOME}/om-server/om/ldapserver/ldapserver/local/script

Step 3 Run the following command to unlock the LDAP user or management account:

./ldapserver_unlockUsers.sh *USER_NAME*

In the command, *USER_NAME* indicates the name of the user to be unlocked.

For example, to unlock the LDAP management **account cn=krbkdc,ou=Users,dc=hadoop,dc=com**, run the following command:

./ldapserver_unlockUsers.sh krbkdc

After the script is executed, enter the password of user **krbkdc** next to **ROOT_DN_PASSWORD**. If the following command output is displayed, the account is successfully unlocked:

```
Unlock user krbkdc successfully.
```

----End

10.13.2.1.2 Internal an Internal System User

Scenario

If the service is abnormal, the internal user of the system may be locked. Unlock the user promptly, or the cluster cannot run properly. System internal users cannot be unlocked using FusionInsight Manager.

Prerequisites

You have obtained the default password of the LDAP administrator **cn=root,dc=hadoop,dc=com**.

Procedure

Step 1 Use the following method to confirm whether the internal system username is locked:

1. OLdap port number obtaining method:
   a. Log in to FusionInsight Manager, choose **System** > **OMS** > **oldap** > **Modify Configuration**.
   b. The **LDAP Listening Port** parameter value is **oldap port**.
2. Domain name obtaining method:
   a. Log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**.
   b. The **Local Domain** parameter value is the domain name.

      For example, the domain name of the current system is **9427068F-6EFA-4833-B43E-60CB641E5B6C.COM**.
3. Run the following command on each node in the cluster as user **omm** to query the number of password authentication failures:

   ldapsearch -H ldaps://*OMS Floating IP Address***:***OLdap port* **-LLL -x -D cn=root,dc=hadoop,dc=com -b krbPrincipalName=***Internal system username***@***Domain name***,cn=***Domain name***,cn=krbcontainer,dc=hadoop,dc=com -w** *Password of LDAP administrator* **-e ppolicy | grep krbLoginFailedCount**

   For example, run the following command to check the number of password authentication failures for user **oms/manager**:

   ldapsearch -H ldaps://10.5.146.118:21750 -LLL -x -D cn=root,dc=hadoop,dc=com -b krbPrincipalName=oms/manager@9427068F-6EFA-4833-B43E-60CB641E5B6C.COM,cn=9427068F-6EFA-4833-B43E-60CB641E5B6C.COM,cn=krbcontainer,dc=hadoop,dc=com -w *Password of user cn=root,dc=hadoop,dc=com* **-e ppolicy | grep krbLoginFailedCount**

   ```
   krbLoginFailedCount: 5
   ```
4. Log in to FusionInsight Manager, choose **System** > **Permission** > **Security Policy** > **Password Policy**.
5. Check the value of the **Password Retries** parameter. If the value is less than or equal to the value of **krbLoginFailedCount**, the user is locked.

   NOTE

   You can also check whether internal users are locked by viewing operations logs.

Step 2 Log in to the active management node as user **omm** and run the following command to unlock the user:

sh ${BIGDATA_HOME}/om-server/om/share/om/acs/config/unlockuser.sh --userName *Internal system username*

Example: **sh ${BIGDATA_HOME}/om-server/om/share/om/acs/config/unlockuser.sh --userName oms/manager**

----End

10.13.2.1.3 Enabling and Disabling Permission Verification on Cluster Components

Scenario

HDFS and ZooKeeper verify the permission of users who attempt to access the services in both security and normal clusters by default. Users without related permission cannot access resources in HDFS and ZooKeeper. When the cluster is deployed in normal mode, HBase and Yarn do not verify the permission of users who attempt to access the services by default. All users can access resources in HBase and Yarn.

Based on actual service requirements, administrators can enable permission verification on HBase and Yarn or disable permission verification on HDFS and ZooKeeper in normal clusters.

Impact on the System

After the enabling and disabling operations, the service configuration will expire. You need to restart the corresponding service for the configuration to take effect.

Enabling Permission Verification on HBase

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services** > **HBase** and click **Configurations**.

Step 3 Click **All Configurations**.

Step 4 Search for parameters **hbase.coprocessor.region.classes**, **hbase.coprocessor.master.classes**, and **hbase.coprocessor.regionserver.classes**.

Add the coprocessor parameter **org.apache.hadoop.hbase.security.access.AccessController** to the end of the values of the preceding parameters, and use a comma (,) to separate the values from those of the original coprocessors.

Step 5 Click **Save**, click **OK**, and wait for message "Operation successful" to display.

----End

Disabling Permission Verification on HBase

NOTE

After HBase permission verification is disabled, the existing permission data will be retained. If you want to delete permission information, disable permission verification, enter the HBase shell, and delete table **hbase:acl**.

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services** > **HBase** and click **Configurations**.

Step 3 Click **All Configurations**.

Step 4 Search for parameters **hbase.coprocessor.region.classes**, **hbase.coprocessor.master.classes**, and **hbase.coprocessor.regionserver.classes**.

Delete the coprocessor parameter **org.apache.hadoop.hbase.security.access.AccessController**.

Step 5 Click **Save**, click **OK**, and wait for message "Operation successful" to display.

----End

Disabling Permission Verification on HDFS

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services** > **HDFS** and click **Configurations**.

Step 3 Click **All Configurations**.

Step 4 Search for parameters **dfs.namenode.acls.enabled** and **dfs.permissions.enabled**.

- **dfs.namenode.acls.enabled** indicates whether to enable HDFS ACL. The default value is **true**, indicating that the ACL is enabled. Change the value to **false**.
- **dfs.permissions.enabled** indicates whether to enable permission check for HDFS. The default value is **true**, indicating that permission check is enabled. Change the value to **false**. After the modification, the owner, owner group, and permission of the directories and files in HDFS remain unchanged.

Step 5 Click **Save**, click **OK**, and wait for message "Operation successful" to display.

----End

Enabling Permission Verification on Yarn

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services** > **Yarn** and click **Configurations**.

Step 3 Click **All Configurations**.

Step 4 Search for parameter **yarn.acl.enable**.

yarn.acl.enable indicates whether to enable the permission check for Yarn.

- In normal clusters, the value is set to **false** by default to disable permission check. To enable permission check, change the value to **true**.
- In security clusters, the value is set to **true** by default to enable authentication.

Step 5 Click **Save**, click **OK**, and wait for message "Operation successful" to display.

----End

Disabling Permission Verification on ZooKeeper

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services** > **ZooKeeper** and click **Configurations**.

Step 3 Click **All Configurations**.

Step 4 Search for parameter **skipACL**.

skipACL indicates whether to skip the ZooKeeper permission check. The default value is **no**, indicating that permission check is enabled. Change the value to **yes**.

Step 5 Click **Save**, click **OK**, and wait for message "Operation successful" to display.

----End

10.13.2.1.4 Logging In to a Non-Cluster Node Using a Cluster User in Normal Mode

Scenario

When the cluster is installed in normal mode, the component clients do not support security authentication and cannot use the **kinit** command. Therefore, nodes outside the cluster cannot use users in the cluster by default. This may result in a user authentication failure when one of these nodes access a component server.

The node administrator can configure a user who has the same name as that of a user for a node outside the cluster, allow the user to log in to the node using the SSH protocol, and connect to the servers of components in the cluster by using the user who logs in to the OS.

Prerequisites

- Nodes outside the cluster can connect to the service plane of the cluster.
- The KrbServer service of the cluster is running properly.
- You have obtained the password of user **root** of the node outside the cluster.
- A human-machine user has been planned and added to the cluster, and you have obtained the authentication credential file. For details, see **Creating a User** and **Exporting an Authentication Credential File**.

Procedure

Step 1 Log in to the node where a user is to be added as user **root**.

Step 2 Run the following command:

rpm -qa | grep pam and **rpm -qa| grep krb5-client**

The following RPM packages are displayed:

```
pam_krb5-32bit-2.3.1-47.12.1
pam-modules-32bit-11-1.22.1
yast2-pam-2.17.3-0.5.211
pam-32bit-1.1.5-0.10.17
pam_mount-32bit-0.47-13.16.1
pam-config-0.79-2.5.58
pam_krb5-2.3.1-47.12.1
pam-doc-1.1.5-0.10.17
pam-modules-11-1.22.1
pam_mount-0.47-13.16.1
pam_ldap-184-147.20
pam-1.1.5-0.10.17
krb5-client-1.6.3
```

Step 3 Check whether the RPM packages in the list are installed in the OS.

- If yes, go to **Step 5**.
- If no, go to **Step 4**.

Step 4 Obtain the lacked RPM packages from the OS image, upload the files to the current directory, and run the following command to install the RPM package:

rpm -ivh *.rpm

NOTE

The RPM packages to be installed may bring security risks. The risks that may be brought by the installation of these RPM packages must be taken into consideration during OS hardening.

After the RPM packages are installed, go to **Step 5**.

Step 5 Run the following command to configure Kerberos authentication on PAM:

pam-config --add --krb5

NOTE

If you need to cancel Kerberos authentication and system user login on a non-cluster node, run the **pam-config --delete --krb5** command as user **root**.

Step 6 Decompress the authentication credential file to obtain **krb5.conf**, use WinSCP to upload this configuration file to the **/etc** directory on the node outside the cluster, and run the following command to configure related permission to enable other users to access the file, such as permission **604**:

chmod 604 /etc/krb5.conf

Step 7 Run the following command in the connection session as user **root** to add the corresponding OS user to the human-machine user, and specify **root** as the primary group.

The OS user password is the same as the initial password when the human-machine user is created on Manager.

useradd *User name* **-m -d /home/admin_test -g root -s /bin/bash**

For example, if the name of the human-machine user is **admin_test**, run the following command:

useradd admin_test -m -d /home/admin_test -g root -s /bin/bash

NOTE

When you use the newly added OS user to log in to the node by using the SSH protocol for the first time, the system prompts that the password has expired after you enter the user password, and the system prompts that the password needs to be changed after you enter the user password again. You need to enter a new password that meets the password complexity requirements of both the node OS and the cluster.

----End

10.13.2.2 Changing the Password for a System User

10.13.2.2.1 Changing the Password for User admin

Scenario

User **admin** is the system administrator account of FusionInsight Manager. You are advised to periodically change the password on FusionInsight Manager to improve system security.

Procedure

Step 1 Log in to FusionInsight Manager.

User **admin** is required for login.

Step 2 Move the cursor to **Hello, admin** in the upper right corner of the page.

In the displayed menu, click **Change Password**.

Step 3 Set **Old Password**, **New Password**, and **Confirm Password**, and click **OK**.

The password must meet the following complexity requirements by default:

- The password contains 8 to 64 characters.
- The password contains at least four types of the following characters: Uppercase letters, lowercase letters, digits, spaces, and special characters which can only be ~`!?,.;-_'(){}[]/<>@#$%^&*+|\=.
- The password cannot be the same as the username or the username spelled backwards.
- The password cannot be a common easily-cracked passwords.
- The password cannot be the same as the password used in the last *N* times. *N* indicates the value of **Repetition Rule** in **Configuring Password Policies**.

----End

10.13.2.2.2 Changing the Password for an OS User

Scenario

During FusionInsight Manager installation, the system automatically creates user **omm** and **ommdba** on each node in the cluster. Periodically change the login passwords of the OS users **omm** and **ommdba** of the cluster node to improve the system O&M security.

The passwords of users **omm** and **ommdba** of the nodes can be different.

Prerequisites

- You have obtained the IP address of the node where the passwords of users **omm** and **ommdba** are to be changed.
- You have obtained the password of user **root** before changing the passwords of users **omm** and **ommdba**.

Changing the Password of an OS User

Step 1 Log in to the node where the password is to be changed as user **root**.

Step 2 Run the following command to change the user password:

passwd *ommdba*

Red Hat system displays the following information:

```
Changing password for user ommdba.
New password:
```

Step 3 Enter a new password. The policy for changing the password of an OS user varies according to the OS that is actually used.

```
Retype New Password:
Password changed.
```

----End

10.13.2.2.3 Changing the OS User Password Validity Period

Scenario

By default, the password validity period of an OS user is 90 days. This topic describes how to change the validity period.

You are advised to periodically change a user's login password of the cluster node operating system to improve system O&M security.

Procedure

Step 1 Log in to the node where you want to change the password validity period of the OS user password as the **root** user.

Step 2 Change the OS user password validity period.

- **Legacy users**

  Run the following command to change the password validity period:

  chage -M*Validity period (days) user_name*

  NOTE

  - *Validity period (days)*: how many days the password is valid since its creation. If this parameter is set to **99999**, the password never expires. Set this parameter based on the site requirements.
  - *user_name*: OS user whose validity period you want to change, for example, **ommdba**.
  - You are advised to set this parameter based on service demands and periodically change the user password.

- **New users**

  Run the following command to edit the file and change the value of **PASS_MAX_DAYS**, which indicates the password validity period, in days. If the value is changed to **99999**, the password never expires.

  vi /etc/login.defs

----End

10.13.2.3 Changing the Password for a System Internal User

10.13.2.3.1 Changing the Password for the Kerberos Administrator

Scenario

It is recommended that the administrator periodically change the password of Kerberos administrator **kadmin** to improve the system O&M security.

If the user password is changed, the OMS Kerberos administrator password is changed as well.

Prerequisites

You have installed the client on any node in the cluster and obtained the IP address of the node.

Procedure

Step 1 Log in to the node where the client is installed as user **root**.

Step 2 Run the following command to go to the client directory, for example, **/opt/hadoopclient**:

cd /opt/hadoopclient

Step 3 Run the following command to set environment variables:

source bigdata_env

Step 4 Run the following command to change the password for **kadmin/admin**. The password changing takes effect on all servers. Keep the password secure because it cannot be retrieved once lost.

kpasswd kadmin/admin

The password must meet the following complexity requirements by default:

- The password contains at least 8 characters.
- The password contains at least four types of the following characters: Uppercase letters, lowercase letters, digits, spaces, and special characters which can only be ~`!?,.;-_'(){}[]/<>@#$%^&*+|\=.
- The password cannot be the same as the username or the username spelled backwards.
- The password cannot be a common easily-cracked passwords.
- The password cannot be the same as the password used in the last *N* times. *N* indicates the value of **Repetition Rule** in **Configuring Password Policies**.

----End

10.13.2.3.2 Changing the Password for the OMS Kerberos Administrator

Scenario

It is recommended that the administrator periodically change the password of OMS Kerberos administrator **kadmin** to improve the system O&M security.

If the user password is changed, the Kerberos administrator password is changed as well.

Procedure

Step 1 Log in to any management node in the cluster as user **omm**.

Step 2 Run the following command to go to the related directory:

cd ${BIGDATA_HOME}/om-server/om/meta-0.0.1-SNAPSHOT/kerberos/scripts

Step 3 Run the following command to set environment variables:

source component_env

Step 4 Run the following command to change the password for **kadmin/admin**. The password changing takes effect on all servers. Keep the password secure because it cannot be retrieved once lost.

kpasswd kadmin/admin

The password must meet the following complexity requirements by default:

- The password contains at least 8 characters.
- The password contains at least four types of the following characters: uppercase letters, lowercase letters, digits, and special characters can only be ~`!?,.:;-_'(){}[]/<>@#$%^&*+|\=.
- The password cannot be the same as the username or the username spelled backwards.
- The password cannot be a common easily-cracked passwords.
- The password cannot be the same as the password used in the last *N* times. *N* indicates the value of **Repetition Rule** in **Configuring Password Policies**.

----End

10.13.2.3.3 Changing the Password for a Component Running User

Scenario

It is recommended that the administrator periodically change the password for each component running user to improve the system O&M security.

Component running users can be classified into the following two types depending on whether their initial passwords are randomly generated by the system:

- If the initial password of a component running user is randomly generated by the system, the user is of the machine-machine type.
- If the initial password of a component running user is not randomly generated by the system, the user is of the human-machine type.

Impact on the System

If the initial password is randomly generated by the system, the cluster needs to be restarted for the password changing to take effect. Services are unavailable during the restart.

Prerequisites

You have installed the client on any node in the cluster and obtained the IP address of the node.

Procedure

Step 1 Log in to the node where the client is installed as the client installation user

Step 2 Run the following command to switch to the client directory, for example, **/opt/client**:

cd /opt/client

Step 3 Run the following command to set environment variables:

source bigdata_env

Step 4 Run the following command and enter the password of user **kadmin/admin** to log in to the **kadmin** console:

kadmin -p kadmin/admin

NOTE

The default password of user **kadmin/admin** can be obtained by contacting the system administrator. The password will expire upon your first login. Change the password as prompted. Keep the password secure because it cannot be retrieved once lost.

Step 5 Run the following command to change the password of an internal component running user.

cpw *Internal system username*

Example: **cpw hdfs**

User **hdfs** is an example. Replace it with the actual username.

The password must meet the following complexity requirements by default:

- Contains at least 8 characters.
- Contains at least four types of the following: uppercase letters, lowercase letters, numbers, spaces, and special characters (~`!?,.;-_'(){}[]/<>@#$%^&*+|\=).
- Cannot be the same as the username or the username spelled backwards.
- Cannot be a common easily-cracked password.
- Cannot be the same as the password used in the latest *N* times. *N* indicates the value of **Repetition Rule** configured in **Configuring Password Policies**. This policy applies only to human-machine accounts.

NOTE

Run the following command to check user information:

getprinc *Internal system username*

Example: **getprinc hdfs**

Step 6 Determine the type of the user whose password needs to be changed.

- If the user is a machine-machine user, go to **Step 7**.
- If the user is a human-machine user, the password is changed successfully and no further action is required.

Step 7 Log in to FusionInsight Manager.

Step 8 In the upper right corner of **Homepage**, click **More** and select **Restart**.

Step 9 In the displayed dialog box, enter the password of the current login user and click **OK**.

Step 10 In the displayed restart confirmation dialog box, click **OK**.

Step 11 Wait for message "Operation successful" to display.

----End

10.13.2.4 Changing the Password for a Database User

10.13.2.4.1 Changing the Password of the OMS Database Administrator

Scenario

It is recommended that the administrator periodically change the password of the OMS database administrator to improve the system O&M security.

Procedure

Step 1 Log in to the active management node as user **root**.

NOTE

The password of user **ommdba** cannot be changed on the standby management node. Otherwise, the cluster may not work properly. Change the password on the active management node only.

Step 2 Run the following command to switch to another user:

su - omm

Step 3 Run the following command to switch the directory:

cd $OMS_RUN_PATH/tools

Step 4 Run the following command to change the password for user **ommdba**:

mod_db_passwd ommdba

Step 5 Enter the old password of user **ommdba** and enter a new password twice.

The password must meet the following complexity requirements:

- Contains 16 to 32 characters.
- Contains at least three types of the following: uppercase letters, lowercase letters, numbers, and special characters (~`!@#$%^&*()-+_=\|[{}];,<.>/?).
- Cannot be the same as the username or the username spelled backwards.
- Cannot be the same as the last 20 historical passwords.

If the following information is displayed, the password is changed:

```
Congratulations, update [ommdba] password successfully.
```

----End

10.13.2.4.2 Changing the Password for the Data Access User of the OMS Database

Scenario

It is recommended that the administrator periodically change the password of the user accessing the OMS database to improve the system O&M security.

Impact on the System

The OMS service needs to be restarted for the new password to take effect. The service is unavailable during the restart.

Procedure

Step 1 On FusionInsight Manager, choose **System** > **OMS** > **gaussDB** > **Change Password**.

Step 2 Locate the row where user **omm** is located and click **Change Password** in the **Operation** column.

Step 3 In the displayed dialog box, enter the password of the current login user and click **OK**.

Step 4 Enter the old and new passwords as prompted.

The password must meet the following complexity requirements:

- Contains 8 to 32 characters.
- Contains at least three types of the following: uppercase letters, lowercase letters, numbers, and special characters (~`!@#$%^&*()-+_=\|[{}];,<.>/?).
- Cannot be the same as the username or the username spelled backwards.
- Cannot be the same as the last 20 historical passwords.

Step 5 Click **OK**. Wait until the system displays a message indicating that the operation is successful.

Step 6 Locate the row where user **omm** is located and click **Restart OMS Service** in the **Operation** column.

Step 7 In the displayed dialog box, enter the password of the current login user and click **OK**.

Step 8 In the displayed restart confirmation dialog box, click **OK** to restart the OMS service.

----End

10.13.2.4.3 Resetting the Component Database User Password

Scenario

Default passwords for components in the MRS cluster to connect to the DBService database are random. You are advised to periodically reset the passwords of component database users to improve system O&M security.

Impact on the System

To reset passwords, you need to stop and then restart services, during which services are unavailable.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services**.

Step 2 Click the name of the service whose database user password is to be reset, for example, **Kafka**, and click **Stop Service** on the **Dashboard** page.

In the displayed dialog box, enter the password of the current login user and click **OK**.

After confirming the impact of stopping the service, wait until the service is stopped.

Step 3 On the **Dashboard** page, choose **More** > **Reset Database Password**.

In the displayed dialog box, enter the password of the current login user and click **OK**.

Select "I have read the information and understand the impact", and click **OK**.

Step 4 After the password is reset, click **Start Service** on the **Dashboard** page.

Step 5 In the displayed dialog box, click **OK** and wait until the service is started.

----End

10.13.2.4.4 Resetting the Password for User omm in DBService

Scenario

The default password of the DBService database user **omm** in the MRS cluster is randomly generated. Periodically reset the password to improve system O&M security.

Impact on the System

Services need to be stopped and restarted and therefore become unavailable during this period.

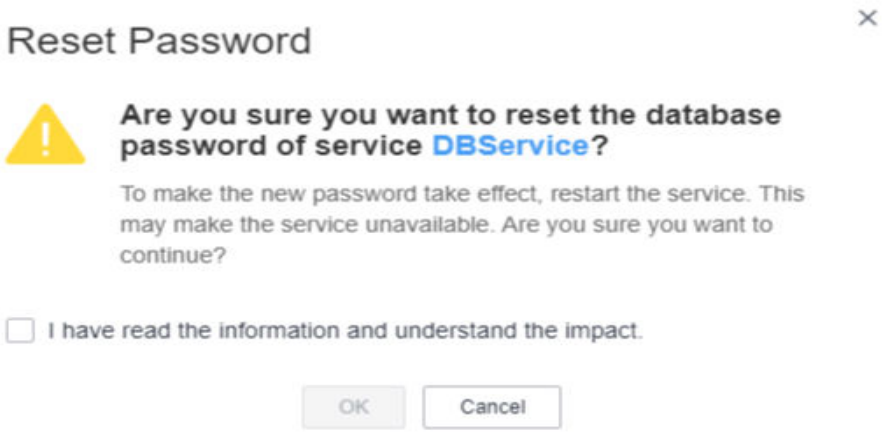
Procedure

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **DBService**.

Step 2 On the **Dashboard** page, click **More** and select **Reset Database Password**.

In the displayed dialog box, enter the password of the current login user and click **OK**.

Select **I have read the information and understand the impact**, and click **OK**.



Step 3 After the password is reset, click **More** and select **Restart Service** on the **Dashboard** page.

In the displayed dialog box, enter the password of the current login user and click **OK**.

Confirm the impact of restarting the service, click **OK**, and wait until the service is started.

----End

10.13.2.4.5 Changing the Password for User compdbuser of the DBService Database

Scenario

It is recommended that the administrator periodically change the password of the OMS database administrator to improve the system O&M security.

Procedure

Step 1 Log in to FusionInsight Manager, choose **Cluster** > **Services** > **DBService**, click **Instance**, and view the IP address of the active DBService node.

Step 2 Log in to the active DBService node as user **root**.

NOTE

The password of user **compuserdb** cannot be changed on the standby DBService node. Change the password on the active management node only.

Step 3 Switch to the **$DBSERVER_HOME** directory and configure environment variables:

su - omm

cd $DBSERVER_HOME

source .dbservice_profile

Step 4 Run the following command to change the password of user **compdbuser** as user **omm** of the DBService database:

gsql -U omm -W omm*Password of user omm of the DBService database* **-d postgres -p 20051 -c "alter user compdbuser identified by '***New password***' valid until '***Expiration time***';"**

NOTE

- The default password of the DBService database user **omm** is randomly generated by the system. For details about how to obtain a random password, Contact the system administrator.
- The new password must meet the following complexity requirements:
  - The password contains 16 to 32 characters.
  - The password contains at least three types of the following: uppercase letters, lowercase letters, digits, and special characters ('~!@#$%^&*()-_=+\|[{}];:'",<.>/?).
  - The password cannot be the same as the username or the username spelled backwards.
  - The password cannot be the same as the last 20 historical passwords.
- The expiration time format is xxxx-xx-xx, for example, **2020-10-31**.

If the following information is displayed, the modification is successful:

```
ALTER ROLE
```

----End

10.13.3 Security Hardening

10.13.3.1 Hardening Policies

Hardening Tomcat

Tomcat is hardened as follows based on open-source software during FusionInsight Manager software installation and use:

- Upgrade Tomcat to the official stable version.
- Permissions on the directories under applications are set to **500**, and the write permission on some directories is supported.
- The Tomcat installation package is automatically deleted after the system software is installed.
- The automatic deployment function is disabled for projects in application directories. Only the **web**, **cas**, and **client** projects are deployed.
- Some unused **http** methods are disabled, preventing attacks by using the **http** methods.

- The default shutdown port and command of the Tomcat server are changed to prevent hackers from shutting down the server and attacking servers and applications.
- To ensure security, the value of **maxHttpHeaderSize** is changed, which enables server administrators to control abnormal requests of clients.
- The Tomcat version description file is modified after Tomcat is installed.
- To prevent disclosure of Tomcat information, the Server attributes of Connector are modified so that attackers cannot obtain information about the server.
- Permissions on files and directories of Tomcat, such as the configuration files, executable files, log directories, and temporary folders, are under control.
- Session facade recycling is disabled to prevent request leakage.
- LegacyCookieProcessor is used as CookieProcessor to prevent the leakage of sensitive data in cookies.

Hardening LDAP

LDAP is hardened as follows after a cluster is installed:

- In the LDAP configuration file, the password of the administrator account is encrypted using SHA. After the OpenLDAP is upgraded to 2.4.39 or later, data is automatically synchronized between the active and standby LDAP nodes using the SASL External mechanism, which prevents disclosure of the password.
- The LDAP service in the cluster supports the SSLv3 protocol by default, which can be used safely. When the OpenLDAP is upgraded to 2.4.39 or later, the LDAP automatically uses TLS1.0 or later to prevent unknown security risks.

Hardening JDK

- If the client process uses the AES256 encryption algorithm, JDK security hardening is required. The operations are as follows:

  Obtain the Java Cryptography Extension (JCE) package whose version matches that of JDK. The JCE package contains **local_policy.jar** and **US_export_policy.jar**. Copy the JAR files to the following directory and replace the files in the directory.

  - Linux: *JDK installation directory*/**jre/lib/security**
  - Windows: *JDK installation directory***jre\lib\security**

  NOTE

  Access the Open JDK open-source community to obtain the JCE file.

- If the client process uses the SM4 encryption algorithm, the JAR package needs to be updated.

  Obtain **SMS4JA.jar** in the *client installation directory*/**JDK/jdk/jre/lib/ext/** directory, and copy the JAR package to the following directory:

  - Linux: *JDK installation directory*/**jre/lib/ext/**
  - Windows: *JDK installation directory***jre\lib\ext**

10.13.3.2 Configuring a Trusted IP Address to Access LDAP

Scenario

By default, the LDAP service deployed in the OMS and cluster can be accessed by any IP address. To enable the LDAP service to be accessed by only trusted IP addresses, you can configure the INPUT policy in the iptables filtering list.

Impact on the System

After the configuration, the LDAP service cannot be accessed by IP addresses that are not configured. Before the expansion, the added IP addresses need to be configured as trusted IP addresses.

Prerequisites

- You have collected the management plane IP addresses and service plane IP addresses of all nodes in the cluster and all floating IP addresses.
- You have obtained the **root** user account for all nodes in the cluster.

Procedure

Configuring trusted IP addresses for the LDAP service on the OMS

Step 1 Confirm the management node IP address. For details, see **Logging In to the Management Node**.

Step 2 Log in to FusionInsight Manager. For details, see **Logging In to FusionInsight Manager**.

Step 3 Choose **System** > **OMS** and choose **oldap** > **Modify Configuration** to view the OMS LDAP port number, that is, the value of **LDAP Listening Port**. The default port number is **21750**.

Step 4 Log in to the active management node as user **root** using the IP address of the active management node.

Step 5 Run the following command to check the INPUT policy in the iptables filtering list:

iptables -L

For example, if no rule is configured, the INPUT policy is displayed as follows:

```
Chain INPUT (policy ACCEPT)
target     prot opt source               destination
```

Step 6 Run the following command to configure all IP addresses used by the cluster as trusted IP addresses. Each IP address needs to be added independently.

iptables -A INPUT -s *Trusted IP address* **-p tcp --dport** *Port number* **-j ACCEPT**

For example, to configure **10.0.0.1** as a trusted IP address and enable it to access port **21750**, you need to run the following command:

iptables -A INPUT -s 10.0.0.1 -p tcp --dport 21750 -j ACCEPT

Step 7 Run the following command to configure all IP addresses as untrusted IP addresses. The trusted IP addresses will not be affected by this rule.

iptables -A INPUT -p tcp --dport *Port number* **-j DROP**

For example, to disable all IP addresses to access port **21750**, run the following command:

iptables -A INPUT -p tcp --dport 21750 -j DROP

Step 8 Run the following command to view the modified INPUT policy in the iptables filtering list:

iptables -L

For example, after a trusted IP address is configured, the INPUT policy is displayed as follows:

```
Chain INPUT (policy ACCEPT)
target     prot opt source               destination
ACCEPT     tcp  --  10.0.0.1             anywhere            tcp dpt:21750
DROP       tcp  --  anywhere             anywhere            tcp dpt:21750
```

Step 9 Run the following command to view the rules and rule numbers in the iptables filtering list:

iptables -L -n --line-number

```
Chain INPUT (policy ACCEPT)
num target     prot opt source               destination
1   DROP       tcp  --  0.0.0.0/0            0.0.0.0/0           tcp dpt:21750
```

Step 10 Run the following command to delete the desired rule from the iptables filtering list based on site requirement:

iptables -D INPUT *Number of the rule to be deleted*

For example, to delete rule 1, run the following command:

iptables -D INPUT 1

Step 11 Log in to the standby management node as user **root** using the standby IP address. Repeat **Step 5** to **Step 10**.

Configuring trusted IP addresses for the LDAP service in the cluster

Step 12 Log in to FusionInsight Manager.

Step 13 Choose **Cluster** > **Services** > **LdapServer**. Click **Instance** and view the LDAP nodes.

Step 14 Go to the **Configurations** page, and view the LDAP port number of the cluster, that is, the value of **LDAP_SERVER_PORT**. The default value is **21780**.

Step 15 Log in to the LDAP node as user **root** using the LDAP service IP address.

Step 16 Run the following command to view the INPUT policy in the iptables filtering list:

iptables -L

For example, if no rule is configured, the INPUT policy is displayed as follows:

```
Chain INPUT (policy ACCEPT)
target     prot opt source               destination
```

Step 17 Run the following command to configure all IP addresses used by the cluster as trusted IP addresses. Each IP address needs to be added independently.

iptables -A INPUT -s *Trusted IP address* **-p tcp --dport** *Port number* **-j ACCEPT**

For example, to configure **10.0.0.1** as a trusted IP address and enable it to access port **21780**, you need to run the following command:

iptables -A INPUT -s 10.0.0.1 -p tcp --dport 21780 -j ACCEPT

Step 18 Run the following command to configure all IP addresses as untrusted IP addresses. The trusted IP addresses will not be affected by this rule.

iptables -A INPUT -p tcp --dport *Port number* **-j DROP**

For example, to disable all IP addresses to access port **21780**, run the following command:

iptables -A INPUT -p tcp --dport 21780 -j DROP

Step 19 Run the following command to view the modified INPUT policy in the iptables filtering list:

iptables -L

For example, after a trusted IP address is configured, the INPUT policy is displayed as follows:

```
Chain INPUT (policy ACCEPT)
target     prot opt source               destination
ACCEPT     tcp  --  10.0.0.1            anywhere            tcp dpt:21780
DROP       tcp  --  anywhere            anywhere            tcp dpt:21780
```

Step 20 Run the following command to view the rules and rule numbers in the iptables filtering list:

iptables -L -n --line-number

```
Chain INPUT (policy ACCEPT)
num target     prot opt source               destination
1   DROP       tcp  --  0.0.0.0/0           0.0.0.0/0           tcp dpt:21780
```

Step 21 Run the following command to delete the desired rule from the iptables filtering list based on site requirement:

iptables -D INPUT *Number of the rule to be deleted*

For example, to delete rule 1, run the following command:

iptables -D INPUT 1

Step 22 Log in to the LDAP node as user **root** using the IP address of another LDAP service, and repeat **Step 16** to **Step 21**.

----End

10.13.3.3 HFile and WAL Encryption

HFile and WAL Encryption

NOTICE

- Setting the HFile and WAL encryption mode to SMS4 or AES has a great impact on the system and will cause data loss in case of any misoperation. Therefore, this operation is not recommended.
- Batch data import using Bulkload does not support data encryption.

HFile and Write ahead log (WAL) in HBase are not encrypted by default. To encrypt them, perform the following operations.

Step 1 On any HBase node, run the following commands to create a key file as user **omm**:

sh ${BIGDATA_HOME}/FusionInsight_HD_8.3.1/install/FusionInsight-HBase-*/hbase/bin/hbase-encrypt.sh *<path>/hbase.jks <type> <length> <alias>*

- */<path>/hbase.jks* indicates the path for storing the generated JKS file.
- *<type>* indicates the encryption type, which can be SMS4 or AES.
- *<length>* indicates the key length. SMS4 supports 16-bit and AES supports 128-bit.
- *<alias>* indicate the alias of the key file. When you create the key file for the first time, retain the default value **omm**.

For example, to generate an SMS4 encryption key, run the following command:

sh ${BIGDATA_HOME}/FusionInsight_HD_8.3.1/install/FusionInsight-HBase-*/hbase/bin/hbase-encrypt.sh /home/hbase/conf/hbase.jks SMS4 16 omm

To generate an AES encryption key, run the following command:

sh ${BIGDATA_HOME}/FusionInsight_HD_8.3.1/install/FusionInsight-HBase-*/hbase/bin/hbase-encrypt.sh /home/hbase/conf/hbase.jks AES 128 omm

NOTE

- To ensure operations can be successfully performed, the **<path>/hbase.jks** directory needs to be created in advance, and the cluster operation user must have the **rw** permission of this directory.
- After running the command, enter the same *<password>* four times. The password encrypted in **Step 3** is the same as the password in this step.

Step 2 Distribute the generated key files to the same directory on all nodes in the cluster and assign read and write permission to user **omm**.

NOTE

- Administrators need to select a safe procedure to distribute keys based on the enterprise security requirements.
- If the key files of some nodes are lost, repeat the step to copy the key files from other nodes.

Step 3 On FusionInsight Manager, set **hbase.crypto.keyprovider.parameters.encryptedtext** to the encrypted password. Set **hbase.crypto.keyprovider.parameters.uri** to the path and name of the key file.

- The format of **hbase.crypto.keyprovider.parameters.uri** is **jceks://** *<key_Path_Name>*.

  <key_Path_Name> indicates the path of the key file. For example, if the path of the key file is **/home/hbase/conf/hbase.jks**, set this parameter to **jceks:///home/hbase/conf/hbase.jks**.

- The format of **hbase.crypto.keyprovider.parameters.encryptedtext** is *<encrypted_password>*.

  <encrypted_password> indicates the encrypted password generated during the key file creation. The parameter value is displayed in ciphertext. Run the following command as user **omm** to obtain the related encrypted password on the nodes where HBase service is installed:

  sh ${BIGDATA_HOME}/FusionInsight_HD_8.3.1/install/FusionInsight-HBase-*/hbase/bin/hbase-encrypt.sh

  NOTE

  After running the command, you need to enter **<password>**. The password is the same as that entered in **Step 1**.

Step 4 On FusionInsight Manager, set **hbase.crypto.key.algorithm** to **SMS4** or **AES** to use SMS4 or AES for HFile encryption.

Step 5 On FusionInsight Manager, set **hbase.crypto.wal.algorithm** to **SMS4** or **AES** to use SMS4 or AES for WAL encryption.

Step 6 On FusionInsight Manager, set **hbase.regionserver.wal.encryption** to **true**.

Step 7 Save the settings and restart the HBase service for the settings to take effect.

Step 8 Create an HBase table through CLI or code and configure the encryption mode to enable encryption. **<type>** indicates the encryption type, and **d** indicates the column family.

- When you create an HBase table through CLI, set the encryption mode to SMS4 or AES for the column family.

  create '*<table name>*', {*NAME => 'd'*, ***ENCRYPTION => '****<type>*'}

- When you create an HBase table using code, set the encryption mode to SMS4 or AES by adding the following information to the code:

```
public void testCreateTable()
{
   String tableName = "user";
   Configuration conf = getConfiguration();
   HTableDescriptor htd = new HTableDescriptor(TableName.valueOf(tableName));

   HColumnDescriptor hcd = new HColumnDescriptor("d");
   //Set the encryption mode to SMS4 or AES.
   hcd.setEncryptionType("<type>");
   htd.addFamily(hcd);

   HBaseAdmin admin = null;
   try
   {
      admin = new HBaseAdmin(conf);
```

```
        if(!admin.tableExists(tableName))
        {
            admin.createTable(htd);
        }
    }
    catch (IOException e)
    {
        e.printStackTrace();
    }
    finally
    {
        if(admin != null)
        {
            try
            {
                admin.close();
            }
            catch (IOException e)
            {
                e.printStackTrace();
            }
        }
    }
}
```

Step 9 If you have configured SMS4 or AES encryption by performing **Step 1** to **Step 7**, but do not set the related encryption parameter when creating the table in **Step 8**, the inserted data is not encrypted.

In this case, you can perform the following steps to encrypt the inserted data:

1. Run the **flush** command for the table to import the data in the memory to the HFile.

   flush *'<table_name>'*

2. Run the following commands to modify the table properties:

   disable *'<table_name>'*

   alter *'<table_name>'*,**NAME=>** *'<column_name>'*,**ENCRYPTION =>** *'<type>'*

   enable *'<table_name>'*

3. Insert a new data record and flush the table.

   NOTE

   A new data record must be inserted so that the HFile will generate a new HFile and the unencrypted data inserted previously will be rewritten and encrypted.

   put *'<table_name>'*, **'id2','f1:c1','value22222222222222222222222222222222'**

   flush *'<table_name>'*

4. Perform the following step to rewrite the HFile:

   major_compact'*<table_name>*'

NOTICE

During this step, the HBase table is disabled and cannot provide services. Exercise caution when you perform this step.

----End

Modifying a Key File

NOTICE

Modifying a key file has a great impact on the system and will cause data loss in case of any misoperation. Therefore, this operation is not recommended.

During the **HFile and WAL Encryption** operation, the related key file must be generated and its password must be set to ensure system security. After a period of running, you can replace the key file with a new one to encrypt HFile and WAL.

Step 1 Run the following command to generate a new key file as user **omm**:

sh ${BIGDATA_HOME}/FusionInsight_HD_8.3.1/install/FusionInsight-HBase-*/hbase/bin/hbase-encrypt.sh *<path>/hbase.jks <type> <length> <alias-new>*

- *<path>/hbase.jks*: indicates the path for storing the generated **hbase.jks** file. The path and file name must be consistent with those of the key file generated in **HFile and WAL Encryption**.
- *<alias-new>*: indicates the alias of the key file. The alias must be different with that of the old key file.
- *<type>*: indicates the encryption type, which can be SMS4 or AES.
- *<length>* indicates the key length. SMS4 supports 16-bit and AES supports 128-bit.

For example, to generate an SMS4 encryption key, run the following command:

sh ${BIGDATA_HOME}/FusionInsight_HD_8.3.1/install/FusionInsight-HBase-*/hbase/bin/hbase-encrypt.sh /home/hbase/conf/hbase.jks SMS4 16 omm_new

To generate an AES encryption key, run the following command:

sh ${BIGDATA_HOME}/FusionInsight_HD_8.3.1/install/FusionInsight-HBase-*/hbase/bin/hbase-encrypt.sh /home/hbase/conf/hbase.jks AES 128 omm_new

NOTE

- To ensure operations can be successfully performed, the **<path>/hbase.jks** directory needs to be created in advance, and the cluster operation user must have the **rw** permission of this directory.
- After running the command, you need to enter the same *<password>* for three times. This password is the password of the key file. You can use the password of the old file without any security risk.

Step 2 Distribute the generated key files to the same directory on all nodes in the cluster and assign read and write permission to user **omm**.

NOTE

Administrators need to select a safe procedure to distribute keys based on the enterprise security requirements.

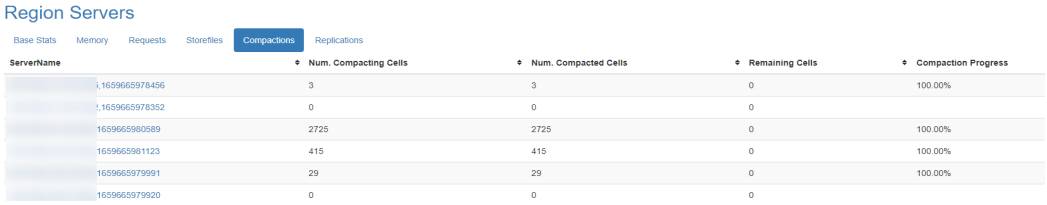
Step 3 On the HBase service configuration page of FusionInsight Manager, add custom configuration items, set **hbase.crypto.master.key.name** to **omm_new**, set **hbase.crypto.master.alternate.key.name** to **omm**, and save the settings.

Step 4 Restart the HBase service for the configuration to take effect.

Step 5 In HBase shell, run the **major compact** command to generate the HFile file based on the new encryption algorithm.

major_compact *'<table_name>'*

Step 6 You can view the major compact progress from the HMaster web page.



Step 7 When all items in **Compaction Progress** reach **100%** and those in **Remaining KVs** are **0**, run the following command as user **omm** to destroy the old key file:

sh ${BIGDATA_HOME}/FusionInsight_HD_8.3.1/install/FusionInsight-HBase-*/hbase/bin/hbase-encrypt.sh *<path>/hbase.jks <alias-old>*

- *<path>/hbase.jks*: indicates the path for storing the generated **hbase.jks** file. The path and file name must be consistent with those of the key file generated in **HFile and WAL Encryption**.
- *<alias-old>*: indicates the alias of the old key file to be deleted.

For example:

sh ${BIGDATA_HOME}/FusionInsight_HD_8.3.1/install/FusionInsight-HBase-*/hbase/bin/hbase-encrypt.sh /home/hbase/conf/hbase.jks omm

NOTE

To ensure operations can be successfully performed, the **<path>/hbase.jks** directory needs to be created in advance, and the cluster operation user must have the **rw** permission of this directory.

Step 8 Repeat **Step 2** and distribute the updated key files again.

Step 9 Delete the HBase self-defined configuration item **hbase.crypto.master.alternate.key.name** added in **Step 3** from FusionInsight Manager.

Step 10 Repeat **Step 4** for the configuration take effect.

----End

10.13.3.4 Configuring Hadoop Security Parameters

Configuring Security Channel Encryption

The channels between components are not encrypted by default. You can set the following parameters to configure security channel encryption.

To modify parameters, log in to FusionInsight Manager, choose **Cluster** > **Services** > *Service name*, click **Configurations** then **All Configurations**, and enter a parameter name in the search box.

NOTE

Restart corresponding services for the modification to take effect after you modify configuration parameters.

Table 10-99 Parameter description

Service	Parameter	Description	Default Value
HBase	hbase.rpc.protection	Indicates whether the HBase channels, including the remote procedure call (RPC) channels for HBase clients to access the HBase server and the RPC channels between the HMaster and RegionServer, are encrypted. If this parameter is set to **privacy**, the channels are encrypted and the authentication, integrity, and privacy functions are enabled. If this parameter is set to **integrity**, the channels are not encrypted and only the authentication and integrity functions are enabled. If this parameter is set to **authentication**, the channels are not encrypted, only packets are authenticated, and integrity and privacy are not required. **NOTE** The privacy mode encrypts transmitted content, including sensitive information such as user tokens, to ensure the security of the transmitted content. However, this mode has great impact on performance. Compared with the other two modes, this mode reduces read/write performance by about 60%. Modify the configuration based on the enterprise security requirements. The configuration items on the client and server must be the same.	• Security mode: privacy • Normal mode: authentication
HDFS	dfs.encrypt.data.transfer	Indicates whether the HDFS data transfer channels and the channels for clients to access HDFS are encrypted. The HDFS data transfer channels include the data transfer channels between DataNodes and the Data Transfer (DT) channels for clients to access DataNodes. The value **true** indicates that the channels are encrypted. The channels are not encrypted by default.	false

Service	Parameter	Description	Default Value
HDFS	dfs.encrypt.data.transfer.algorithm	Indicates whether the HDFS data transfer channels and the channels for clients to access HDFS are encrypted. This parameter is valid only when **dfs.encrypt.data.transfer** is set to **true**. The default value is **3des**, indicating that 3DES algorithm is used to encrypt data. The value can also be set to **rc4**. However, to avoid security risks, you are not advised to set the parameter to this value.	3des
HDFS	hadoop.rpc.protection	Indicates whether the RPC channels of each module in Hadoop are encrypted. The channels include: ● RPC channels for clients to access HDFS ● RPC channels between modules in HDFS, for example, between DataNode and NameNode ● RPC channels for clients to access Yarn ● RPC channels between NodeManager and ResourceManager ● RPC channels for Spark to access Yarn and HDFS ● RPC channels for MapReduce to access Yarn and HDFS ● RPC channels for HBase to access HDFS The default value is **privacy**, indicating encrypted transmission. The value **authentication** indicates that transmission is not encrypted. **NOTE** You can set this parameter on the HDFS component configuration page. The parameter setting is valid globally, that is, the setting of whether the RPC channel is encrypted takes effect on all modules in Hadoop.	● Security mode: **privacy** ● Normal mode: **authentication**

Setting the Maximum Number of Concurrent Web Connections

To ensure web server reliability, new connections are rejected when the number of user connections reaches a specific threshold. This prevents DDOS attacks and

service unavailability caused by too many users accessing the web server at the same time.

To modify parameters, log in to FusionInsight Manager, choose **Cluster** > **Services** > *Service name*, click **Configurations** then **All Configurations**, and enter a parameter name in the search box.

Table 10-100 Parameter description

Service	Parameter	Description	Default Value
HDFS/Yarn	hadoop.http.server.MaxRequests	Specifies the maximum number of concurrent web connections of each component.	2000
Spark	spark.connection.maxRequest	Specifies the maximum number of request connections of JobHistory.	5000

10.13.3.5 Configuring an IP Address Whitelist for Modification Allowed by HBase

If the Replication function is enabled for HBase clusters, a protection mechanism for data modification is added on the standby HBase cluster to ensure data consistency between the active and standby clusters. Upon receiving an RPC request for data modification, the standby HBase cluster checks the permission of the user who sends the request (only HBase manage users have the modification permission). Then it checks the validity of the source IP address of the request. Only modification requests from IP addresses in the white list are accepted. The IP address white list is configured by the **hbase.replication.allowedIPs** item.

Log in to FusionInsight Manager and choose **Cluster** > **Services** > **HBase**. Click **Configurations** and enter the parameter name in the search box.

Table 10-101 Parameter description

Parameter	Description	Default Value
hbase.replication.allowedIPs	Allows replication request processing from configured IP addresses only. It supports comma separated regex patterns. Each pattern can be any of the following: • Regex pattern Example: 10.18.40.*, 10.18.*, 10.18.40.11 • Range pattern (Range can be specified only in the last octet) Example: 10.18.40.[10-20] If this item is empty (default value), the white list contains only the IP address of the RegionServer of the cluster, indicating that only modification requests from the RegionServer of the standby HBase cluster are accepted.	N/A

10.13.3.6 Updating a Key for a Cluster

Scenario

When a cluster is installed, an encryption key is generated automatically by the system so that the security information in the cluster (such as all database user passwords and key file access passwords) can be stored in encryption mode. After the cluster is installed, if the original key is accidentally disclosed or a new key is required, you can manually update the key.

Impact on the System

- After a cluster key is updated, a new key is generated randomly in the cluster. This key is used to encrypt and decrypt the newly stored data. The old key is not deleted, and it is used to decrypt data encrypted using the old key. After security information is modified, for example, a database user password is changed, the new password is encrypted using the new key.
- When a key is updated for a cluster, the cluster must be stopped and cannot be accessed.

Prerequisites

- You have obtained the IP addresses of the active and standby management nodes. For details, see **Logging In to the Management Node**.
- You have stopped the upper-layer service applications that depend on the cluster.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 In the upper right corner of **Homepage**, click **Stop**. In the dialog box displayed, enter the password of the current user for identity confirmation.

and click **OK**. Wait for a while until a message indicating that the operation is successful is displayed.

Step 3 Log in to the active management node as user **omm**.

Step 4 Run the following command to disable logout upon timeout:

TMOUT=0

NOTE

After the operations in this section are complete, run the **TMOUT=***Timeout interval* command to restore the timeout interval in a timely manner. For example, **TMOUT=600** indicates that a user is logged out if the user does not perform any operation within 600 seconds.

Step 5 Run the following command to go to the related directory:

cd ${BIGDATA_HOME}/om-server/om/tools

Step 6 Run the following command to update the cluster key:

sh updateRootKey.sh

Enter **y** as prompted.

```
The root key update is a critical operation.
Do you want to continue?(y/n):
```

If the following information is displayed, the key is updated successfully.

```
Step 4-1: The key save path is obtained successfully.
...
Step 4-4: The root key is sent successfully.
```

Step 7 In the upper right corner of **Homepage**, click **Start**.

In the displayed dialog box, click **OK**. Wait until a message is displayed, indicating that the startup is successful.

----End

10.13.3.7 Changing the Cluster Encryption Mode

Scenario

This section describes how to change the encryption mode of a cluster.

Impact on the System

When changing the encryption mode of a cluster, the cluster and OMS node are stopped and cannot be accessed.

Prerequisites

The upper-layer applications depending on the cluster are stopped.

Procedure

Step 1 Log in to FusionInsight Manager as user **admin**.

Step 2 In the upper right corner of **Homepage**, click **Stop**. In the dialog box displayed, enter the password of the current user for identity confirmation.

and click **OK**. Wait for a while until a message indicating that the operation is successful is displayed.

Step 3 Log in to the active management node as user **root** and run the following command to switch to user **omm**:

su - omm

Step 4 Run the following command to check the current encryption mode of the cluster (that is, the value of the **defaultAlgorithm** parameter in the **scc.conf** file):

cat $BIGDATA_COMMON/securityforscc/config/scc.conf

For example, the following information indicates that the current cluster is encrypted using the general encryption algorithm.

```
.....
defaultAlgorithm=AES256_GCM
.....
```

Step 5 Run the following commands to change the cluster encryption mode, for example, to SMCompatible:

cd $CONTROLLER_HOME/tools

bash updateSysSecretMain.sh -o update -a *SMCompatible*

For details about the parameters of the script for changing the encryption mode, see **Reference Information**.

The cryptographic algorithm is successfully changed if the following information is displayed:

```
start to pre-action(update)
end to pre-action(update)
Operations(update) need to be performed on 3 nodes in the cluster.
start to execute action(update) on node[No:1, ip:192.168.43.43, nodeType:oms-node-active]
end to execute action(update) on node[No:1, ip:192.168.43.43, nodeType:oms-node-active]
.....
start to post-action(update)
end to post-action(update)
execute action(update) success.
```

Step 6 Run the following command to check view cluster encryption mode:

cat $BIGDATA_COMMON/securityforscc/config/scc.conf

```
.....
defaultAlgorithm=SM4_CTR
.....
```

Step 7 In the upper right corner of **Homepage**, click **More** and select **Synchronize Configurations**. In the dialog box displayed, click **OK** to synchronize configurations for the current cluster. Wait until the synchronization is complete.

Step 8 Click **Start**. In the displayed dialog box, click **OK**. Wait until a message is displayed indicating that the startup is successful.

Step 9 Check whether the cluster is successfully started and all services are running properly.

- If yes, go to **Step 10**.
- If no, go to **Step 11**.

Step 10 After the cluster is started and services are running properly, run the following commands on the active management node of the cluster to delete the files related to the old key:

cd $CONTROLLER_HOME/tools

bash updateSysSecretMain.sh -o commit

The operation is successful if the following information is displayed:

```
Operations(commit) need to be performed on 3 nodes in the cluster.
start to execute action(commit) on node[No:1, ip:192.168.43.43, nodeType:oms-node-active]
end   to execute action(commit) on node[No:1, ip:192.168.43.43, nodeType:oms-node-active]
......
execute action(commit) success.
```

Step 11 If the cluster fails to be started or the service running status is abnormal, run the following commands on the active management node of the cluster to roll back to the state before the encryption mode of the cluster is changed. If the rollback fails, contact technical support.

cd $CONTROLLER_HOME/tools

bash updateSysSecretMain.sh -o rollback

The operation is successful if the following information is displayed:

```
start to pre-action(rollback)
end to pre-action(rollback)
Operations(rollback) need to be performed on 3 nodes in the cluster.
start to execute action(rollback) on node[No:1, ip:192.168.43.43, nodeType:oms-node-active]
end   to execute action(rollback) on node[No:1, ip:192.168.43.43, nodeType:oms-node-active]
......
start to post-action(rollback)
end to post-action(rollback)
execute action(rollback) success.
```

Run the following command to submit the rollback operation:

bash updateSysSecretMain.sh -o commit

The operation is successful if the following information is displayed:

```
Operations(commit) need to be performed on 3 nodes in the cluster.
start to execute action(commit) on node[No:1, ip:192.168.43.43, nodeType:oms-node-active]
end   to execute action(commit) on node[No:1, ip:192.168.43.43, nodeType:oms-node-active]
......
execute action(commit) success.
```

----End

Reference Information

The following describes the parameters of the script for changing the encryption mode.

```
help:
  parameters:
     -o: Operation Type, Mandatory parameters, Enumerated Value: update | commit | rollback
     -a: Algorithm Type, Optional parameters(Required only for update operation), Enumerated Value:
generalCipher | SMCompatible | SMOnly
  usage:
     updateSysSecretMain.sh -o [ update | commit | rollback ] | [ -a [ generalCipher | SMCompatible |
SMOnly ] ]
```

- **-o**: indicates the supported operations for changing the encryption mode of a cluster key, including the update, rollback, and commit operations. The update or rollback operation is followed by a commit operation, which is used to submit the current operation result.
- **-a**: indicates the type of an encryption mode. The update operation supports the following key modes:
  - **generalCipher**: indicates that the general encryption mode is used.
  - **SMCompatible/SMOnly**: indicates that the national encryption mode is used.

10.13.3.8 Hardening the LDAP

Configuring the LDAP Firewall Policy

In the cluster adopting the dual-plane networking, the LDAP is deployed on the service plane. To ensure the LDAP data security, you are advised to configure the firewall policy in the cluster to disable relevant LDAP ports.

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services** > **LdapServer** and click **Configurations**.

Step 3 Check the value of **LDAP_SERVER_PORT**, which is the service port of LdapServer.

Step 4 To ensure data security, configure the firewall policy for the whole cluster to disable the LdapServer port based on the customer's firewall environment.

----End

Enabling the LDAP Audit Log Output

Users can set the audit log output level of the LDAP service and output audit logs in a specified directory, for example, **/var/log/messages**. The logs output can be used to check user activities and operation commands.

NOTE

If the function of LDAP audit log output is enabled, massive logs are generated, affecting the cluster performance. Exercise caution when enabling this function.

Step 1 Log in to any LdapServer node.

Step 2 Run the following command to edit the **slapd.conf.consumer** file, and set the value of **loglevel** to **256** (you can run the **man slapd.conf** command on the OS to view the log level definition).

cd ${BIGDATA_HOME}/FusionInsight_BASE_8.3.1/install/FusionInsight-ldapserver-2.7.0/ldapserver/local/template

vi slapd.conf.consumer

```
...
pidfile         [PID_FILE_SLAPD_PID]
argsfile        [PID_FILE_SLAPD_ARGS]
loglevel   256
...
```

Step 3 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **LdapServer**. Click **More** and select **Restart Service**. In the dialog box displayed, verify the current user identity, and restart the service.

----End

10.13.3.9 Configuring Kafka Data Encryption During Transmission

Scenario

Data between the Kafka client and the broker is transmitted in plain text. The Kafka client may be deployed in an untrusted network, exposing the transmitting data to leakage and tampering risks.

Procedure

The channel between components is not encrypted by default. You can set the following parameters to enable security channel encryption.

To modify parameters, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Kafka**, and click **Configurations** then **All Configurations**. Enter a parameter name in the search box.

NOTE

After the configuration, restart the corresponding service for the settings to take effect.

Table 10-102 describes the parameters related to transmission encryption on the Kafka server.

Table 10-102 Parameters relevant to Kafka data encryption during transmission

Parameter	Description	Default Value
ssl.mode.enable	Indicates whether to enable the Secure Sockets Layer (SSL) protocol. If this parameter is set to **true**, services relevant to the SSL protocol are started during the broker startup.	false

Parameter	Description	Default Value
security.inter.broker.protocol	Indicates communication protocol between brokers. The communication protocol can be PLAINTEXT, SSL, SASL_PLAINTEXT, or SASL_SSL.	SASL_PLAINTEXT

The SSL protocol can be configured for the server or client to encrypt transmission and communication only after **ssl.mode.enable** is set to **true** and broker enables the **SSL** and **SASL_SSL** protocols.

10.13.3.10 Configuring HDFS Data Encryption During Transmission

Configuring HDFS Security Channel Encryption

The channel between components is not encrypted by default. You can set parameters to enable security channel encryption.

To modify parameters, log in to FusionInsight Manager, choose **Cluster** > **Services** > **HDFS**, and click **Configurations** then **All Configurations**. Enter a parameter name in the search box.

NOTE

After the configuration, restart the corresponding service for the settings to take effect.

Table 10-103 Parameters

Configuration Item	Description	Default Value
hadoop.rpc.protection	**NOTICE** • The setting takes effect only after the service is restarted. Rolling restart is not supported. • After the setting, you need to download the client configuration file again. Otherwise, HDFS cannot provide the read and write services. • After the setting, you need to restart the executor. Otherwise, the job management and file management functions on the console become unavailable. Indicates whether the RPC channels of each module in Hadoop are encrypted. The channels include: • RPC channels for clients to access HDFS • RPC channels between modules in HDFS, for example, between DataNode and NameNode • RPC channels for clients to access Yarn • RPC channels between NodeManager and ResourceManager • RPC channels for Spark to access Yarn and HDFS • RPC channels for MapReduce to access Yarn and HDFS • RPC channels for HBase to access HDFS • RPC channels for CDL to submit tasks **NOTE** The setting takes effect globally, that is, the encryption attribute of the RPC channel of each module in the Hadoop takes effect.	• Security mode: privacy • Normal mode: authentication **NOTE** • **authentication**: indicates that only authentication is required. • **integrity**: indicates that authentication and consistency check need to be performed. • **privacy**: indicates that authentication, consistency check, and encryption need to be performed.

Configuration Item	Description	Default Value
dfs.encrypt.data.transfer	Indicates whether the HDFS data transfer channels and the channels for clients to access HDFS are encrypted. The HDFS data transfer channels include the data transfer channels between DataNodes and the Data Transfer (DT) channels for clients to access DataNodes. The value **true** indicates that the channels are encrypted. The channels are not encrypted by default. **NOTE** • This parameter is valid only when **hadoop.rpc.protection** is set to **privacy**. • If a large amount of service data is transmitted, enabling encryption by default severely affects system performance. • If data transmission encryption is configured for one cluster in the trusted cluster, the same data transmission encryption must be configured for the peer cluster.	false
dfs.encrypt.data.transfer.algorithm	Indicates the algorithm to encrypt the HDFS data transfer channels and the channels for clients to access HDFS. This parameter is valid only when **dfs.encrypt.data.transfer** is set to **true**. **NOTE** The default value is **3des**, indicating that 3DES algorithm is used to encrypt data. The value can also be set to **rc4**. However, to avoid security risks, you are not advised to set the parameter to this value.	3des
dfs.encrypt.data.transfer.cipher.suites	This parameter can be left empty or set to **AES/CTR/NoPadding** to specify the cipher suite for data encryption. If this parameter is not specified, the encryption algorithm specified by **dfs.encrypt.data.transfer.algorithm** is used for data encryption. The default value is **AES/CTR/NoPadding**.	AES/CTR/NoPadding

Configuration Item	Description	Default Value
dfs.data.transfer.protection	Whether to encrypt the RPC channel used by the HDFS client to read and write data. There are three encryption methods: • **authentication**: only authentication is required. • **integrity**: authentication and consistency check are required. • **privacy**: authentication, consistency check, and encryption are required. **NOTICE** After the configuration is modified, you need to restart the HDFS service and its upper-layer services. Rolling restart is not supported. Services will be interrupted during the restart. Exercise caution when performing this operation.	-

10.13.3.11 Configuring HetuEngine Data Encryption During Transmission

Scenario

This section describes how to configure HTTPS encryption for communication between nodes in a cluster and configure a whitelist for accessing HSConsole to enhance security.

NOTE

You are advised to use the secure HTTPS protocol. Risks exist if you use an insecure protocol.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **HetuEngine**. Click **Configurations** then **All Configurations**. Enter the parameter name in the search box.

NOTE

After the configuration, restart the corresponding service for the settings to take effect.

Table 10-104 Security configuration

Parameter	Description	Default Value
internal-communication.https.required	Whether communication between nodes in a cluster requires HTTPS encryption. If this option is enabled, the query performance may deteriorate.	true **NOTE** If this parameter is set to **false**, **http-server.http.enabled** must be enabled.
referer.whitelist	Whitelist of web request headers that are allowed to access the HSconsole. Use semicolons (;) to separate multiple whitelists, for example, "https://192.168.1.2:25000:*;https://192.168.1.3:25001:*".	N/A
http-server.https.enabled	Whether to enable HTTPS access for HetuEngine Computer Cluster.	true **NOTICE** If it is set to false, the HTTP protocol is used, please ensure that HetuEngine Compute Instance works in secure context.

----End

10.13.3.12 Configuring RTD Data Encryption During Transmission

Scenario

Configure RTD security channel encryption to enhance security.

Procedure

Step 1 Log in to FusionInsight Manager as a service user and choose **Cluster** > **Services** > **MOTService**. Click **Configurations** then **All Configurations**.

Step 2 Click **MOTServer(Role)**, select **Security**, and check whether the value of the following parameter is **true**. If not, change the value to **true** and save the settings.

Table 10-105 Parameters

Parameter	Description	Example Value
REQUIRE_SSL	The server forcibly requires the SSL connection.	true

Step 3 Click **Dashboard**, click **More**, and select **Restart Service** to restart MOTService as prompted.

Step 4 When creating a MOT cluster tenant, select **Enable SSL**.

1. Log in to FusionInsight Manager as a service user and choose **Cluster** > **Services** > **RTDService**.
2. Click the link next to **RTD WebUI** to access the RTD web UI.
3. Choose **System** > **Tenant Management**. Click **Add**, enter a tenant name, and set **DB Type** to **MOT**.
4. Click **MOT Cluster**, select **Enable SSL** (set other parameters based on site requirements), and click **OK**.

----End

10.13.3.13 Configuring IoTDB Data Encryption During Transmission

Scenario

In security scenarios, IoTDB data transmission encryption is required to ensure data security.

NOTE

Data transmission encryption affects performance. Therefore, you are not advised to enable this function in scenarios that require high performance.

Prerequisites

- Service users of each component are created by the administrator as required. For details, see **Creating a User**. In security mode, machine-machine users need to download the keytab file. For details, see **Exporting an Authentication Credential File**. A human-machine user must change the password upon the first login.
- The IoTDB client has been installed in a directory, for example, **/opt/client**. Choose **Cluster** > **Services** > **IoTDB** then choose **More** > **Download Client**. In the dialog box that is displayed, select **Save to Path**. The generated file is saved to the **/tmp/FusionInsight-Client** directory on the active management node by default.

Procedure

Step 1 Perform operations on the server.

1. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **IoTDB**. Click the **Configurations** tab.

2. Modify the following parameters:
   - Search for **SSL_ENABLE** in the upper right corner of the page and change its value to **true**.
   - Search for **iotdb_server_kerberos_qop** in the upper right corner of the page and change its value to **auth-conf**.
3. Click **Save**. In the **Save Configuration** dialog box, click **OK**.

   When **Operation succeeded** is displayed, click **Finish**.
4. Click the **Dashboard** tab. Choose **More** > **Restart Service**. Wait until the service is restarted.

Step 2 Perform operations on the client.

1. Log in to the active management node as user **root** and run the following command to switch to the client installation directory, for example, **/opt/client**:

   cd /opt/client
2. Run the following command to configure environment variables:

   source bigdata_env
3. (Optional) Run the following command to authenticate the current user if Kerberos authentication is enabled for the cluster. If Kerberos authentication is not enabled, skip this step.

   kinit *Component service user*
4. Run the following commands to generate the **truststore.jks** file using the **ca.crt** certificate file in the root directory of the client:

   cd /tmp/FusionInsight-Client/FusionInsight_Cluster_*_IoTDB_ClientConfig

   keytool -noprompt -import -alias myservercert -file ca.crt -keystore truststore.jks
5. Run the following command to copy the generated **truststore.jks** file to the client installation directory, for example, **/opt/client/IoTDB/iotdb/conf**.

   cp truststore.jks /opt/client/IoTDB/iotdb/conf
6. Run the following command to switch to the directory where the IoTDB client running script is stored:

   cd /opt/client/IoTDB/iotdb/sbin
7. Run the **vim start-cli.sh** command to compile the **start-cli.sh** script and add **iotdb_ssl_truststore=/opt/client/IoTDB/iotdb/conf/truststore.jks** and **iotdb_ssl_enable=true** to the startup parameter **exec "$JAVA" -cp "$JAVA_CLASSPATH" "$JAVA_MAIN_CLASS" $PARAMETERS** in the script.

   ```
   exec "$JAVA" -Diotdb_ssl_truststore=/opt/client/IoTDB/iotdb/conf/truststore.jks -Diotdb_ssl_enable=true -cp "$JAVA_CLASSPATH" "$JAVA_MAIN_CLASS" $PARAMETERS
   ```
8. Run the following command to log in to the client. If the login is successful, data transmission encryption is enabled for IoTDB.

   ./start-cli.sh -h *Service IP address of node where the IoTDBServer instance is located* **-p** *IoTDBServer RPC port*

NOTE

- You can also log in to the client by running the **./start-cli.sh -h** *Service IP address of the node where the IoTDBServer instance is located* **-p** *IoTDBServer RPC port* **-u** *Service username* **-pw** *Service user password* command.
- To view the service IP address of the node where the IoTDBServer instance is located, log in to FusionInsight Manager, choose **Cluster** > **Services** > **IoTDB**, and click the **Instance** tab.
- The default RPC port is **22260**. To obtain the port number, choose **Cluster** > **Services** > **IoTDB**, click **Configurations** then **All Configurations**, and search for **IOTDB_SERVER_RPC_PORT**.

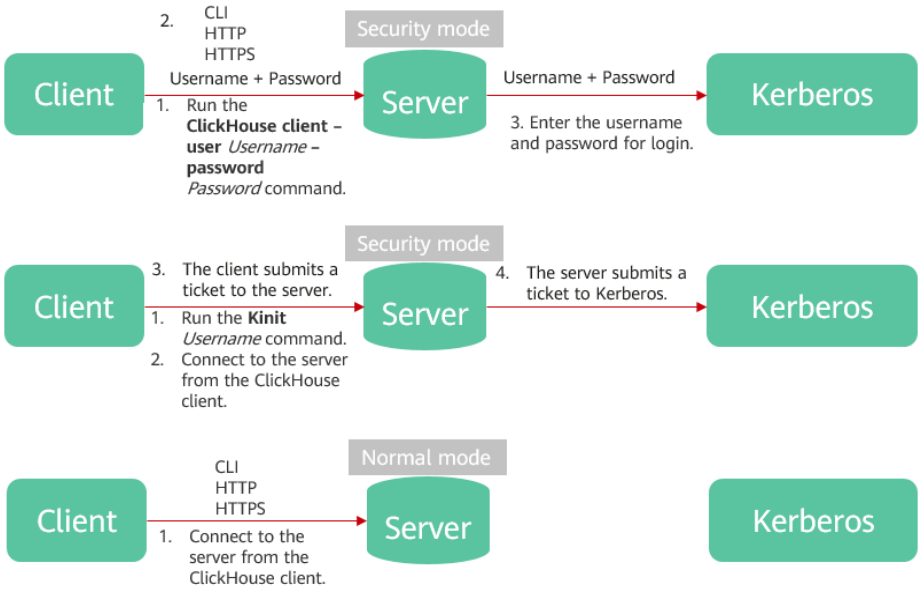
----End

10.13.3.14 ClickHouse Security Hardening

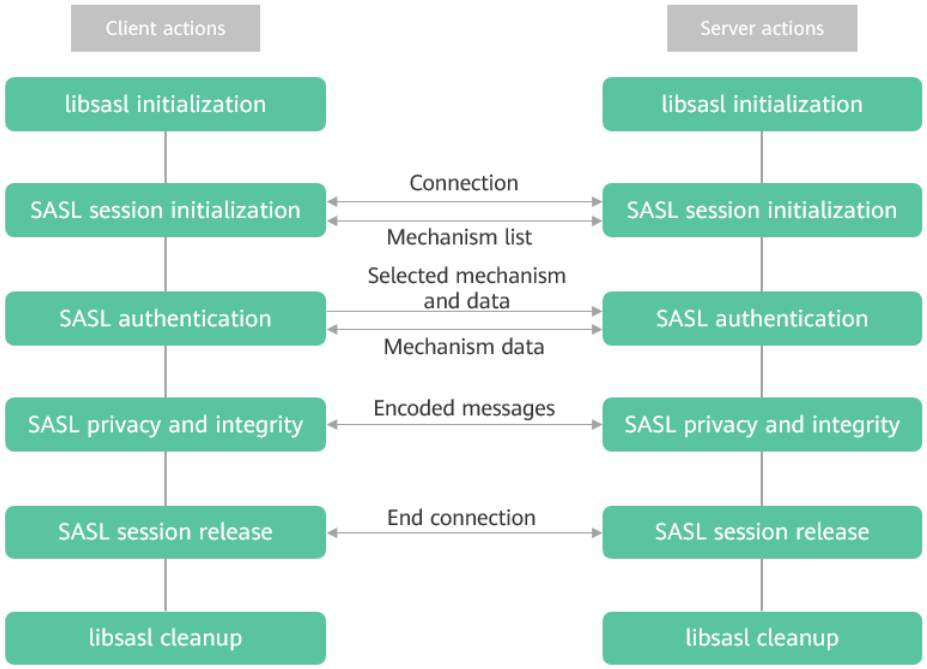
Authentication and Encryption

The authentication system of ClickHouse is as follows:

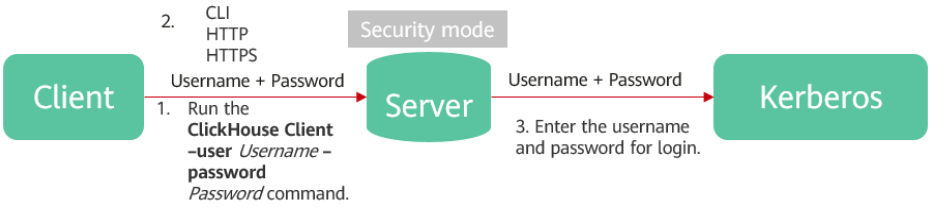
Figure 10-24 ClickHouse system authentication mode



- The normal mode does not require authentication. You can use the built-in default user to log in to the system without authentication.
- The kinit authentication mode of the client in security mode uses the sasl authentication mode. The implementation principle is as follows:



- The client in security mode is compatible with the community version. Kerberos authentication is performed only on the server.



- ClickHouse supports permission management for the following objects:

Resource	Permission
Database	CREATE
Table/View	SELECT/INSERT
Admin	ALL

NOTE

ClickHouse does not support disabling security authentication on a cluster in security mode.

Encrypted Channel

ClickHouse enhances usability based on the open-source community version. By default, clusters in security mode use TCP and HTTP channels encrypted by OpenSSL.

Security Hardening

- Encoding rules

  Description: The same encoding mode is used on the web service client and server to prevent garbled characters and to implement input verification.

Security hardening: Response messages of web servers are encoded using UTF-8.

- IP address whitelist filtering supported for management users

  Description: IP address whitelist filtering is used to prevent unauthorized clients from logging in to the system.

  Security hardening: External nodes are not allowed to access the ClickHouse client as a management user.

- URL injection attack

  Description: A customized UI of data migration is used to prevent URL injection attacks.

  Security hardening: URL and path validity checks are implemented.

- SQL injection attack

  Description: ClickHouse prevents SQL injection attacks.

  Security hardening: SQL statements are precompiled.

- Log injection attack

  Description: Log injection must be prevented to avoid security information leakage.

  Security hardening: Privacy information is encrypted to prevent sensitive stack information from being recorded in logs.

- DDoS attack

  Description: ClickHouse prevents service interruption or exceptions caused by DDoS attacks.

  Security hardening: The number of connections is configurable. The default value is 4096.

- Anti-repudiation

  Description: Audit logs are recorded.

  Security hardening: DDL operations such as write, permission granting and revoking, and data migration are audited.

10.13.3.15 Hive Metastore Security Hardening

Hive Metastore Fine-Grained Authorization

Metastore of Hive 3.*x* supports only StorageBased authorization. This authorization mode depends on the permission of the file system, such as HDFS. The permission is coarse-grained. Metastore fine-grained authorization supports SQLStd and Ranger authorization.

Security hardening points:

- Hive Metastore supports SQLStd or Ranger authorization in the following scenarios:
  - Creating a database
  - Creating a table
  - Creating a UDF

  - Adding a partition
  - Deleting a database
  - Deleting a table
  - Deleting a UDF
  - Modifying a database
  - Modifying a table
  - Modifying a partition
  - Granting a permission
  - Revoking a permission
- Metastore requests sent by Hive Metastore clients, such as HiveServer, Spark, HetuEngine, and Flink, are authorized.

Procedure

Fine-grained authorization is enabled for Hive Metastore by default. You can also disable security hardening and use the original StorageBased authorization by configuring parameters.

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Hive**. Click **Configurations** then **All Configurations**.

Step 2 Search for the following parameters in the search box:

Table 10-106 Hive Metastore fine-grained authorization parameters

Parameter	Description	Default Value
metastore-ext.authorization.enable	Whether to enable Metastore API authorization. After this function is enabled, SQLStd or Ranger authorization is used depending on the value of **metastore-ext.authorization.ranger.and.sqlstd**. If this parameter is set to **false**, the original StorageBased authorization is used.	true

Parameter	Description	Default Value
metastore-ext.authorization.ranger.and.sqlstd	Authorization mode used when **metastore-ext.authorization.enable** is set to **true**. Specifically: • **true**: indicates that Ranger authorization is performed before role authorization. • **false**: indicates that only Ranger or role authorization is used. By default, the authorization mode is the same as that of HiveServer.	false

Step 3 After the modification is complete, click **Save** then **OK**.

Step 4 Click **Dashboard**, click **More**, and select **Restart Service**. Enter the password for verification, and click **OK**.

----End

10.13.3.16 Configuring ZooKeeper SSL

Scenario

By default, SSL channel encryption transmission is disabled between the ZooKeeper client and server and between instances on the server. This section describes how to enable the ZooKeeper channel encryption transmission.

Impact on the System

- When SSL channel encryption transmission is enabled on the ZooKeeper server, the performance deteriorates.
- When SSL channel encryption transmission is enabled on the ZooKeeper server, ZooKeeper and dependent upper-layer components need to be restarted. During the restart, services are unavailable.
- To enable SSL channel encryption transmission on the ZooKeeper server, you need to download the client again.
- If SSL channel encryption transmission is enabled for ZooKeeper, rolling restart is not supported.
- Guardian does not support SSL for ZooKeeper.

Procedure

Step 1 Log in to FusionInsight Manager, click **Cluster** and choose **Services** > **ZooKeeper**. On the displayed page, click **Configurations** and click **All Configurations**.

Step 2 Enter the parameter name in the search box, and change the value as follows:

Table 10-107 Security configuration item

Parameter	Description	Default Value	New Value
ssl.enabled	Whether to enable SSL communication encryption.	false	true

Step 3 After the modification is complete, click **Save** and then click **OK**.

Step 4 Click **Cluster** and choose **Services** > **ZooKeeper**. On the ZooKeeper service page, choose **More** > **Restart Service**, enter the password for authentication, and confirm the operation impact on the **Restart Service** page.

You can select **Restart upper-layer services**. During the restart of all affected components, services will be unavailable. Exercise caution when performing this operation.

Step 5 Click **OK** and wait until the services are restarted successfully.

Step 6 Choose **Cluster** > **Active/Standby Cluster DR** to check whether active/standby DR is configured for the current cluster.

- If yes, go to **Step 7**.
- If no, no further action is required.

Step 7 The **ssl.enabled** configuration of the ZooKeeper service in the active cluster must be the same as that in the DR cluster. Modify the **ssl.enabled** parameter in the cluster where no operation is performed by referring to the preceding steps.

Step 8 Log in to the active OMS node in the active cluster as user **root** and run the following commands to restart the DR management process:

su - omm

${BIGDATA_HOME}/om-server/om/share/om/disaster/sbin/restart-disaster.sh

If the following information is displayed, the operation is successful:

```
...
disaster start with process id : 23256
End into restart-disaster.sh
```

Step 9 Log in to the active OMS node in the DR cluster as user **root** and run the following commands to restart the DR management process:

su - omm

${BIGDATA_HOME}/om-server/om/share/om/disaster/sbin/restart-disaster.sh

Step 10 (Optional) If the cluster uses Flink services, log in to the node where the Flink client is installed as user **root** and run the following command to modify the Flink configuration file:

cd Client installation directory**/client/Flink/flink/conf**

vim flink-conf.yaml

Add the following parameters to the end of **env.java.opts** and save the file:

```
-Dzookeeper.clientCnxnSocket=ClientCnxnSocketNetty -Dzookeeper.client.secure=true
```

Step 11 (Optional) If the cluster uses the HetuEngine service, log in to Manager, restart HSBroker, and then log in to the HetuEngine web UI to restart all compute instances.

----End

10.13.3.17 Encrypting the Communication Between the Controller and the Agent

Scenario

After a cluster is installed, Controller and Agent need to communicate with each other. The Kerberos authentication is used during the communication. By default, the communication is not encrypted during the communication for the sake of cluster performance. Users who have demanding security requirements can use the method described in this section for encryption.

Impact on the System

- Controller and all Agents automatically restart, which interrupts FusionInsight Manager.
- The performance of management nodes deteriorates in large clusters. You are advised to enable the encryption function for clusters with a maximum of 200 nodes.

Prerequisites

You have obtained the IP addresses of the active and standby management nodes.

Procedure

Step 1 Log in to the active management node as user **omm**.

Step 2 Run the following command to disable logout upon timeout:

TMOUT=0

NOTE

After the operations in this section are complete, run the **TMOUT=***Timeout interval* command to restore the timeout interval in a timely manner. For example, **TMOUT=600** indicates that a user is logged out if the user does not perform any operation within 600 seconds.

Step 3 Run the following command to go to the related directory:

cd ${CONTROLLER_HOME}/sbin

Step 4 Run the following command to enable communication encryption:

./enableRPCEncrypt.sh -t

Run the **sh ${BIGDATA_HOME}/om-server/om/sbin/status-oms.sh** command to check whether **ResHAStatus** of the active management node Controller is **Normal**

and whether you can log in to FusionInsight Manager again. If yes, the enablement is successful.

Step 5 Run the following command to disable communication encryption when necessary:

./enableRPCEncrypt.sh -f

Run the **sh ${BIGDATA_HOME}/om-server/om/sbin/status-oms.sh** command to check whether **ResHAStatus** of the active management node Controller is **Normal** and whether you can log in to FusionInsight Manager again. If yes, the enablement is successful.

----End

10.13.3.18 Updating SSH Keys for User omm

Scenario

During cluster installation, the system automatically generates the SSH public key and private key for user **omm** to establish the trust relationship between nodes. After the cluster is installed, if the original keys are accidentally disclosed or new keys are used, the system administrator can perform the following operations to manually change the keys.

Prerequisites

- The cluster has been stopped.
- No other management operations are being performed.

Procedure

Step 1 Log in as user **omm** to the node whose SSH keys need to be replaced.

If the node is a Manager management node, run the following command on the active management node.

Step 2 Run the following command to disable logout upon timeout:

TMOUT=0

NOTE

After the operations in this section are complete, run the **TMOUT=***Timeout interval* command to restore the timeout interval in a timely manner. For example, **TMOUT=600** indicates that a user is logged out if the user does not perform any operation within 600 seconds.

Step 3 Run the following command to generate a key for the node:

- If the node is a Manager management node, run the following command:

  sh ${CONTROLLER_HOME}/sbin/update-ssh-key.sh

- If the node is a non-Manager management node, run the following command:

  sh ${NODE_AGENT_HOME}/bin/update-ssh-key.sh

If "Succeed to update ssh private key." is displayed when the preceding command is executed, the SSH key is generated successfully.

Step 4 Run the following command to transfer the node's public key to the primary management node. Note that this step is necessary even if the current node is the primary management node.

scp ${HOME}/.ssh/id_rsa.pub** *oms_ip*:**${HOME}/.ssh/id_rsa.pub_bak

oms_ip: indicates the IP address of the active management node.

Enter the password of user **omm** to copy the files.

Step 5 Log in to the active management node as user **omm**.

Step 6 Run the following command to disable logout on system timeout:

TMOUT=0

Step 7 Run the following command to go to the related directory:

cd ${HOME}/.ssh

Step 8 Run the following command to add new public keys:

cat id_rsa.pub_bak >> authorized_keys

Step 9 Run the following command to move the temporary public key file, for example, **/tmp**.

mv -f id_rsa.pub_bak /tmp

Step 10 Copy the **authorized_keys** file of the active management node to the other nodes in the cluster:

scp authorized_keys *node_ip*:**/${HOME}/.ssh/authorized_keys**

node_ip: indicates the IP address of another node in the cluster. Multiple IP addresses are not supported.

Step 11 Run the following command to confirm private key replacement without entering the password:

ssh *node_ip*

node_ip: indicates the IP address of another node in the cluster. Multiple IP addresses are not supported.

Step 12 Log in to FusionInsight Manager and click **Start** in the upper right corner of **Homepage** to start the cluster.

----End

10.13.3.19 Changing the Timeout Duration of the Manager Page

FusionInsight Manager allows you to configure the timeout duration of the Manager page based on service requirements. You must properly set the timeout duration to prevent information leakage in long-time exposure of the web page.

Changing the Timeout Duration of the Manager Page

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **OMS**.

Step 3 In the list, locate the row that contains **tomcat** and click **Modify Configuration**.

Step 4 On the displayed page, set **Session Timeout** as required and click **OK**.

NOTICE

- Set the minimum session duration based on service requirements. Otherwise, there will be security risks.
- Currently, you cannot use the method described as follows to change the timeout duration of component web UIs.

----End

10.13.3.20 Resetting Sessions During Secondary Authentication Configuration

Scenario

Before performing important operations, you need to perform secondary authentication on users. You can enable the function of resetting sessions during secondary authentication to invalidate the original sessions.

If session hijacking occurs before secondary authentication, resetting the session can terminate the session hijacking and reduce loss to users.

By default, resetting sessions during secondary authentication is disabled. You can enable the function by following the instructions provided in this section.

NOTE

After secondary authentication is enabled and the session is reset, you will be switched to the login page after you enter the password for secondary authentication and confirm the password, because the heartbeat interface session is reset. In this case, log in again.

Procedure

Step 1 Log in to the active management node as user **omm**.

Step 2 Run the following command to modify the configuration:

vi ${BIGDATA_HOME}/om-server/tomcat/webapps/web/WEB-INF/classes/config/web_security.properties

Set **second_auth_need_refresh_session** to **true**.

Step 3 Run the following command to restart Tomcat:

sh ${BIGDATA_HOME}/om-server/tomcat/bin/shutdown.sh;sh ${BIGDATA_HOME}/om-server/tomcat/bin/startup.sh

Step 4 Log in to the standby management node as user omm, and perform operations in **Step 2**.

----End

10.13.4 Security Maintenance

10.13.4.1 Account Maintenance Suggestions

It is recommended that the administrator conduct routine checks on the accounts. The check covers the following items:

- Check whether the accounts of the OS, FusionInsight Manager, and each component are necessary and whether temporary accounts have been deleted.
- Check whether the permissions of the accounts are appropriate. Different administrators have different rights.
- Check and audit the logins and operation records of all types of accounts.

10.13.4.2 Password Maintenance Suggestions

Accessing portal requires identity authentication. The complexity and validity period of an account password must meet your security requirements.

Refer to the following suggestions to maintain passwords:

1. Assign dedicated personnel to keep OS passwords.
2. Use passwords that meet certain strength requirements, such as minimum password length or mixing of letter cases.
3. Encrypt passwords before transferring them, and do not transfer them via email.
4. Encrypt passwords for storage.
5. Remind enterprise users to change passwords during system handover.
6. Change passwords periodically.

10.13.4.3 Log Maintenance Suggestions

Operation logs help discover exceptions such as illegal operations and login by unauthorized users. The system records important operations in logs. You can use operation logs to locate problems.

Checking Logs Regularly

Check system logs periodically and handle exceptions such as unauthorized operations or logins in a timely manner.

Backing Up Logs Regularly

The audit logs provided by FusionInsight Manager and cluster record the user activities and operations. You can export the audit logs on FusionInsight Manager. If there are too many audit logs in the system, you can configure dump

parameters to dump audit logs to a specified server to ensure that the cluster nodes disk space is sufficient.

Maintenance Owner

Network monitoring engineers and system maintenance engineers

10.13.5 Security Statement

JDK Usage Statement

MRS MRS cluster is a big data cluster that provides users with distributed data analysis and computing capabilities. The built-in JDK of MRS MRS is OpenJDK, which is used in the following scenarios:

- Platform service running and maintenance
- Linux client operations, including service submission and application O&M

JDK Risk Description

The system performs permission control on the built-in JDK. Only users in the related group of the FusionInsight platform can access the JDK. In addition, the platform is deployed on a customer's intranet. Therefore, the security risk is low.

JDK Hardening

For details about how to harden the JDK, see "Hardening JDK" in **Hardening Policies**.

Public IP Addresses in Hue

Hue uses the test cases of third-party packages, such as **ipadrress**, **requests**, and **Django**, and uses the public IP addresses in the comments of the test cases. However, these public IP addresses are not involved when Hue provides services, and the Hue configuration file does not involve these public IP addresses.

11 Alarm Reference

11.1 ALM-12001 Audit Log Dumping Failure

Alarm Description

Cluster audit logs need to be dumped on a third-party server due to the local historical data backup policy. The system starts to check the dump server at 3 a.m. every day. If the dump server meets the configuration conditions, audit logs can be successfully dumped. This alarm is generated when the audit log dump fails if the disk space of the dump directory on the third-party server is insufficient or a user changes the username, password, or dump directory of the dump server.

Alarm Attributes

Alarm ID	Alarm Severity	Alarm Type	Service Type	Auto Cleared
12001	Minor	Quality of service	FusionInsight Manager	Yes

Alarm Parameters

Type	Parameter	Description
Location Information	Source	Specifies the cluster or system for which the alarm is generated.
	ServiceName	Specifies the service for which the alarm is generated.
	RoleName	Specifies the role for which the alarm is generated.
	HostName	Specifies the host for which the alarm is generated.

Impact on the System

System can store a maximum of only 50 dump files locally. If the fault persists on the dump server, the local audit logs may be lost, and the first 50 audit logs that exceed the current time cannot be queried.

Possible Causes

- The network connection is abnormal.
- The username, password, or dump directory of the dump server does not meet the configuration conditions.
- The disk space of the dump directory is insufficient.

Handling Procedure

Check whether the network connection is normal.

Step 1 On the FusionInsight Manager home page, choose **Audit > Configurations**.

Step 2 Check whether the SFTP IP on the dump configuration page is valid.

Log in to the node where Manager is located as user **root** and run the **ping** command to check whether the network connection between the SFTP server and the cluster is normal.

- If yes, go to **Step 5**.
- If no, go to **Step 3**.

Step 3 Repair the network connection, reset the SFTP password, and click **OK**.

Step 4 Wait for 2 minutes and check whether the alarm is cleared.

- If yes, no further action is required.
- If no, go to **Step 5**.

Check whether the username, password, or dump directory are correct.

Step 5 On the dump configuration page, check whether the username, password, and dump directory of the third-party server are correct.

- If yes, go to **Step 8**.
- If no, go to **Step 6**.

Step 6 Change the username, password, or dump directory, reset the SFTP password and click **OK**.

Step 7 Wait for 2 minutes and check whether the alarm is cleared.

- If yes, no further action is required.
- If no, go to **Step 8**.

Check whether the disk space of the dump directory is sufficient.

Step 8 Log in to the third-party server as user **root** and run the **df** command to check whether the disk space of the dump directory of the third-party server exceeds 100 MB.

- If yes, go to **Step 11**.
- If no, go to **Step 9**.

Step 9 Expand disk space capacity for the third-party server, Reset the SFTP password and click **OK**

Step 10 Wait for 2 minutes, view real-time alarms and check whether the alarm is cleared.

- If yes, no further action is required.
- If no, go to **Step 11**.

Reset the dump rule.

Step 11 On the FusionInsight Manager home page, choose **Audit > Configurations**.

Step 12 Reset dump rules, set the parameters properly, and click **OK**.

Step 13 Wait for 2 minutes, view real-time alarms and check whether the alarm is cleared.

- If yes, no further action is required.
- If no, go to **Step 14**.

Collect fault information.

Step 14 On the FusionInsight Manager, choose **O&M**>**Log > Download**.

Step 15 Select **OmmServer** from the **Service** and click **OK**.

Step 16 Click  in the upper right corner, and set **Start Date** and **End Date** for log collection to 10 minutes ahead of and after the alarm generation time, respectively. Then, click **Download**.

Step 17 Contact the O&M engineers and send the collected log information.

----End

Alarm Clearance

After the fault is rectified, the system automatically clears this alarm.

Related Information

None.

11.2 ALM-12004 Manager OLdap Resource Abnormal

Alarm Description

The system checks LDAP resources every 60 seconds. This alarm is generated when the system detects that the LDAP resources in Manager are abnormal for six consecutive times.

This alarm is cleared when the Ldap resource in the Manager recovers and the alarm handling is complete.

Alarm Attributes

Alarm ID	Alarm Severity	Alarm Type	Service Type	Auto Cleared
12004	Major	Quality of service	FusionInsight Manager	Yes

Alarm Parameters

Type	Parameter	Description
Location Information	Source	Specifiestheclusterorsystemforwhichthealarmis-generated.
	ServiceName	Specifies the service for which the alarm is generated.
	RoleName	Specifies the role for which the alarm is generated.
	HostName	Specifies the host for which the alarm is generated.

Impact on the System

Manager active/standby switchover may occur. The Manager and WebUI authentication service of components is unavailable. Security authentication and user management functions cannot be provided for upper-layer web services. As a result, you may fail to log in to the Manager and WebUI of components.

Possible Causes

The LdapServer process in the Manager is abnormal.

Handling Procedure

Check whether the LdapServer process in the Manager is normal.

Step 1 Log in the Manager node in the cluster as user **omm**.

Log in to FusionInsight Manager using the floating IP address, and run the **sh ${BIGDATA_HOME}/om-server/om/sbin/status-oms.sh** command to check the information about the current Manager two-node cluster.

Step 2 Run **ps -ef | grep slapd**command to check whether the LdapServer resource process in the**${BIGDATA_HOME}/om-server/om/** in the process configuration file is running properly.

NOTE

You can determine that the resource is normal by checking the following information:

1. After the **sh ${BIGDATA_HOME}/om-server/om/sbin/status-oms.sh**command runs,**ResHAStatus**of the OLdap is**Normal**.
2. After the **ps -ef | grep slapd** command runs, the slapd process of port 21750 can be viewed.
   - If yes, go to **Step 3**.
   - If no, go to **Step 4**.

Step 3 Run the **kill -2***ldap pid* command to restart the LdapServer process and wait for 20 seconds. The HA starts the OLdap process automatically. Check whether the current OLdap resource is in normal state.

- If yes, the operation is complete.
- If no, go to **Step 4**.

Collect fault information.

Step 4 On the FusionInsight Manager home page, choose **O&M**>**Log > Download**.

Step 5 Select **OmsLdapServer**and**OmmServer**from the**Service** and click **OK**.

Step 6 Click in the upper right corner, and set **Start Date** and **End Date** for log collection to 1 hour ahead of and after the alarm generation time, respectively. Then, click **Download**.

Step 7 Contact the O&M engineers and send the collected log information.

----End

Alarm Clearance

After the fault is rectified, the system automatically clears this alarm.

Related Information

None.

11.3 ALM-12005 Manager OKerberos Resource Abnormal

Alarm Description

The alarm module checks the status of the Kerberos resource in Manager every 80 seconds. This alarm is generated when the alarm module detects that the Kerberos resources are abnormal for six consecutive times.

This alarm is cleared when the Kerberos resource recovers and the alarm handling is complete.

Alarm Attributes

Alarm ID	Alarm Severity	Alarm Type	Service Type	Auto Cleared
12005	Major	Quality of service	FusionInsight Manager	Yes

Alarm Parameters

Type	Parameter	Description
Location Information	Source	Specifiestheclusterorsystemforwhichthealarmis-generated.
	ServiceName	Specifies the service for which the alarm is generated.
	RoleName	Specifies the role for which the alarm is generated.
	HostName	Specifies the host for which the alarm is generated.

Impact on the System

The component WebUI authentication services are unavailable and cannot provide security authentication functions for web upper-layer services. Users may be unable to log in to FusionInsight Manager and the WebUIs of components.

Possible Causes

The OLdap resource on which the Okerberos depends is abnormal.

Handling Procedure

Check whether the OLdap resource on which the Okerberos depends is abnormal in the Manager.

Step 1 Log in the Manager node in the cluster as user **omm**.

Log in to FusionInsight Manager using the floating IP address, and run the **sh ${BIGDATA_HOME}/om-server/om/sbin/status-oms.sh** command to check the information about the current Manager two-node cluster.

Step 2 Run the **sh ${BIGDATA_HOME}/om-server/OMS/workspace0/ha/module/hacom/script/status_ha.sh** command to check whether the OLdap resource status managed by HA is normal. (In single-node mode, the OLdap resource is in the Active_normal state; in the two-node mode, the OLdap resource is in the Active_normal state on the active node and in the Standby_normal state on the standby node.)

- If yes, go to **Step 4**.
- If no, go to **Step 3**.

Step 3 See the procedure in **ALM-12004 Manager OLdap Resource Abnormal** to resolve the problem. After the OLdap resource status recovers, check whether the OKerberos resource status is normal.

- If yes, the operation is complete.
- If no, go to **Step 4**.

Collect fault information.

Step 4 On the FusionInsight Manager home page, choose **O&M**>**Log > Download**.

Step 5 Select **OmsKerberos**and**OmmServer**from the**Service** and click **OK**.

Step 6 Click in the upper right corner, and set **Start Date** and **End Date** for log collection to 1 hour ahead of and after the alarm generation time, respectively. Then, click **Download**.

Step 7 Contact the O&M engineers and send the collected log information.

----End

Alarm Clearance

After the fault is rectified, the system automatically clears this alarm.

Related Information

None.

11.4 ALM-12006 NodeAgent Process Is Abnormal

Alarm Description

Controller checks the NodeAgent heartbeat every 30 seconds. If Controller does not receive heartbeat messages from a NodeAgent, it attempts to restart the NodeAgent process. This alarm is generated if the NodeAgent fails to be restarted for three consecutive times.

This alarm is cleared when Controller can properly receive the status report of the NodeAgent.

Alarm Attributes

Alarm ID	Alarm Severity	Alarm Type	Service Type	Auto Cleared
12006	Major	Quality of service	FusionInsight Manager	Yes

Alarm Parameters

Type	Parameter	Description
Location Information	Source	Specifies the cluster or system for which the alarm is generated.
	ServiceName	Specifies the service for which the alarm is generated.
	RoleName	Specifies the role for which the alarm is generated.
	HostName	Specifies the host for which the alarm is generated.
Additional Information	Detail	Specifies the details for which the alarm is generated.

Impact on the System

NodeAgent process is abnormal, heartbeat messages cannot be reported to the platform. If the problem is caused by network faults, hardware faults, or SSH mutual trust, component services cannot be normal.

Possible Causes

- The network is disconnected, the hardware is faulty, or the operating system runs slowly.
- The memory of the NodeAgent process is insufficient.
- The NodeAgent process is faulty.

Handling Procedure

Check whether the network is disconnected, whether the hardware is faulty, or whether the operating system runs commands slowly.

Step 1 On FusionInsight Manager, choose **O&M** > **Alarm** > **Alarms**. On the page that is displayed, click ⌄ in the row containing the alarm, click the host name, and view the IP address of the host for which the alarm is generated.

Step 2 Log in to the active management node as user **root**.

NOTE

If the faulty node is the active management node and fails login, the network of the active management node may be faulty. In this case, go to **Step 4**.

Step 3 Run the **ping** *IP address of the faulty host* command to check whether the faulty node is reachable.

- If yes, go to **Step 12**.
- If no, go to **Step 4**.

Step 4 Contact the network administrator to check whether the network is faulty.

- If yes, go to **Step 5**.
- If no, go to **Step 6**.

Step 5 Rectify the network fault and check whether the alarm is cleared from the alarm list.

- If yes, no further action is required.
- If no, go to **Step 6**.

Step 6 Contact the hardware administrator to check whether the hardware (CPU or memory) of the node is faulty.

- If yes, go to **Step 7**.
- If no, go to **Step 12**.

Step 7 Repair or replace faulty components and restart the node. Check whether the alarm is cleared.

- If yes, no further action is required.
- If no, go to **Step 8**.

Step 8 If a large number of node faults are reported in the cluster, the floating IP addresses may be abnormal. As a result, Controller cannot detect the NodeAgent heartbeat.

Log in to any management node and view the **/var/log/Bigdata/omm/oms/ha/scriptlog/floatip.log** log to check whether the logs generated one to two minutes before and after the faults occur are complete.

For example, a complete log is in the following format:

```
2017-12-09 04:10:51,000 INFO (floatip) Read from ${BIGDATA_HOME}/om-server_8.1.0.1/om/etc/om/routeSetConf.ini,value is : yes
2017-12-09 04:10:51,000 INFO (floatip) check wsNetExport : eth0 is up.
2017-12-09 04:10:51,000 INFO (floatip) check omNetExport : eth0 is up.
2017-12-09 04:10:51,000 INFO (floatip) check wsInterface : eRth0:oms, wsFloatIp: XXX.XXX.XXX.XXX.
2017-12-09 04:10:51,000 INFO (floatip) check omInterface : eth0:oms, omFloatIp: XXX.XXX.XXX.XXX.
2017-12-09 04:10:51,000 INFO (floatip) check  wsFloatIp : XXX.XXX.XXX.XXX is reachable.
2017-12-09 04:10:52,000 INFO (floatip) check  omFloatIp : XXX.XXX.XXX.XXX is reachable.
```

- If yes, go to **Step 12**.
- If no, go to **Step 9**.

Step 9 Check whether the omNetExport log is printed after the wsNetExport is detected or whether the interval for printing two logs exceeds 10 seconds or longer.

- If yes, go to **Step 10**.
- If no, go to **Step 12**.

Step 10 View the **/var/log/message** file of the OS to check whether sssd frequently restarts or nscd exception information is displayed when the fault occurs.

sssd restart example

```
Feb  7 11:38:16 10-132-190-105 sssd[pam]: Shutting down
Feb  7 11:38:16 10-132-190-105 sssd[nss]: Shutting down
Feb  7 11:38:16 10-132-190-105 sssd[nss]: Shutting down
Feb  7 11:38:16 10-132-190-105 sssd[be[default]]: Shutting down
Feb  7 11:38:16 10-132-190-105 sssd: Starting up
Feb  7 11:38:16 10-132-190-105 sssd[be[default]]: Starting up
Feb  7 11:38:16 10-132-190-105 sssd[nss]: Starting up
Feb  7 11:38:16 10-132-190-105 sssd[pam]: Starting up
```

Example nscd exception information

```
Feb 11 11:44:42 10-120-205-33 nscd: nss_ldap: failed to bind to LDAP server ldaps://10.120.205.55:21780: Can't contact LDAP server
Feb 11 11:44:43 10-120-205-33 ntpq: nss_ldap: failed to bind to LDAP server ldaps://10.120.205.55:21780: Can't contact LDAP server
Feb 11 11:44:44 10-120-205-33 ntpq: nss_ldap: failed to bind to LDAP server ldaps://10.120.205.92:21780: Can't contact LDAP server
```

- If yes, go to **Step 11**.
- If no, go to **Step 12**.

Step 11 Check whether the LdapServer node is faulty, for example, the service IP address is unreachable or the network latency is too high. If the fault occurs periodically, locate and eliminate it and run the **top** command to check whether abnormal software exists.

Check whether the memory of the NodeAgent process is insufficient.

Step 12 Log in to the faulty node as user **root** and run the following command to view the NodeAgent process logs:

vi /var/log/Bigdata/nodeagent/scriptlog/agent_gc.log.*.current

Step 13 Check whether the log file contains an error indicating that the metaspace size or heap memory size is insufficient.

- If yes, go to **Step 14**.
- If no, go to **Step 21**.

Step 14 Run the **su - omm** command to switch to user **omm**, increase the values of **nodeagent.Xms** (initial heap memory) and **nodeagent.Xmx** (maximum heap memory) in the **$NODE_AGENT_HOME/etc/agent/nodeagent.properties** file, and save the modification.

Step 15 Run the following commands to restart the NodeAgent service:

sh ${BIGDATA_HOME}/om-agent/nodeagent/bin/stop-agent.sh

sh ${BIGDATA_HOME}/om-agent/nodeagent/bin/start-agent.sh

Step 16 Wait a moment and check whether this alarm is cleared.

- If yes, no further action is required.
- If no, go to **Step 17**.

Check whether the NodeAgent process is faulty.

Step 17 Log in to the faulty node as user **omm** and run the following command:

ps -ef | grep "Dprocess.name=nodeagent" | grep -v grep

Step 18 Check whether the command output is empty.

- If yes, go to **Step 19**.
- If no, go to **Step 21**.

Step 19 View the NodeAgent startup and run logs to locate the fault. After the fault is rectified, go to **Step 20**.

- NodeAgent run logs: **/var/log/Bigdata/nodeagent/agentlog/agent.log**
- NodeAgent start and stop logs: **/var/log/Bigdata/nodeagent/scriptlog/nodeagent_ctl.log**

Step 20 Run the following commands to restart the NodeAgent service:

sh ${BIGDATA_HOME}/om-agent/nodeagent/bin/stop-agent.sh

sh ${BIGDATA_HOME}/om-agent/nodeagent/bin/start-agent.sh

Collect fault information.

Step 21 On FusionInsight Manager, choose **O&M**. In the navigation pane on the left, choose **Log** > **Download**.

Step 22 Select the following nodes from **Services** and click **OK**.

- NodeAgent
- Controller
- OS

Step 23 Click the edit button in the upper right corner, and set **Start Date** and **End Date** for log collection to 10 minutes ahead of and after the alarm generation time, respectively. Then, click **Download**.

Step 24 Contact O&M engineers and provide the collected logs.

----End

Alarm Clearance

This alarm is automatically cleared after the fault is rectified.

Related Information

None.

11.5 ALM-12007 Process Fault

Alarm Description

The process health check module checks the process status every 5 seconds. This alarm is generated when the process health check module detects that the process connection is faulty for three consecutive times.

This alarm is cleared when the process can be connected.

Alarm Attributes

Alarm ID	Alarm Severity	Alarm Type	Service Type	Auto Cleared
12007	Major	Quality of service	FusionInsight Manager	Yes

Alarm Parameters

Type	Parameter	Description
Location Information	Source	Specifies the cluster or system for which the alarm is generated.
	ServiceName	Specifies the service for which the alarm is generated.
	RoleName	Specifies the role for which the alarm is generated.
	HostName	Specifies the host for which the alarm is generated.
Additional Information	Details	Specifies alarm details.

Impact on the System

The impact varies depending on the instance that is faulty.

For example, if an HDFS instance is faulty, the impacts are as follows:

- If a DataNode instance is faulty, read and write operations cannot be performed on data blocks stored on the DataNode, which may cause data loss or unavailability. However, data in HDFS is redundant. Therefore, the client can access data from other DataNodes.
- If an HttpFS instance is faulty, the client cannot access files in HDFS over HTTP. However, the client can use other methods (such as shell commands) to access files in HDFS.
- If a JournalNode instance is faulty, namespaces and data logs cannot be stored to disks, which may cause data loss or unavailability. However, HDFS stores backups on other JournalNodes. Therefore, the faulty JournalNode can be recovered and data can be rebalanced.
- If a NameNode deployed in active/standby mode is faulty, an active/standby switchover occurs. If only one NameNode is deployed, the client cannot read or write any HDFS data. On MRS, NameNodes must be deployed in two-node mode.
- If a Router instance is faulty, the client cannot access data on the router. However, the client can use other Routers or directly access data on the backend NameNode.
- If a ZKFC instance is faulty, the NameNode does not continuously and automatically fail over. As a result, data cannot be read from or write to HDFS by the client. In this case, you need to enable automatic failover on other available ZKFC instances to restore the HDFS cluster.

Possible Causes

- The instance process is abnormal.

- The drive space is insufficient.

NOTE

If a large number of process fault alarms are reported in the same period, files in the installation directory may be deleted by mistake or the permission may be modified.

Handling Procedure

Check whether the instance process is abnormal.

Step 1 Log in to FusionInsight Manager, choose **O&M** > **Alarm** > **Alarms**, click ⌄ in the row that contains the target alarm, and record the service name in **Location** Information. Click the hostname to view the IP address of the host for which the alarm is generated.

Step 2 On the **Alarms** page, check whether the "ALM-12006 Abnormal NodeAgent Process" alarm is reported.

- If yes, go to **Step 3**.
- If no, go to **Step 4**.

Step 3 Handle the alarm by following the procedure provided in "ALM-12006 Abnormal NodeAgent Process".

Step 4 Log in to the host for which the alarm is generated as user **root**. Check whether the user, user group, and permission of the installation directory where the alarm role is deployed are correct. The correct user, user group, and the permission are **omm**, **ficommon**, and **750**, respectively.

For example, the NameNode installation directory is **${BIGDATA_HOME}/FusionInsight_Current/1_8_NameNode/etc**.

- If yes, go to **Step 6**.
- If no, go to **Step 5**.

Step 5 Run the following commands to set the permission to **750** and **User:Group** to **omm:ficommon**:

chmod 750 *<folder_name>*

chown omm:ficommon *<folder_name>*

Step 6 Wait 5 minutes and check whether this alarm is cleared.

- If yes, no further action is required.
- If no, go to **Step 7**.

Step 7 Log in to the active OMS node as user **root** and run the following command to view the **configurations.xml** file. In the command, *Service name* indicates the service name queried in **Step 1**.

vi $BIGDATA_HOME/components/current/*Service name***/configurations.xml**

Search for **healthMonitor.properties**, locate the health check configuration of the instance for which the alarm is generated, and record the interface or script path specified by **monitor.info**.

View the logs recorded in the interface or script and rectify the fault.
